Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://ipr.etsi.org>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Report (TR) has been produced by ETSI Technical Committee Cyber Security (CYBER).

Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the [ETSI Drafting Rules](#) (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

Executive summary

The present document captures and describes the top twenty Enterprise industry level cybersecurity best practices that provide enhanced cyber security, developed and maintained by the Council on CyberSecurity as an independent, expert, global non-profit organization. The Council provides ongoing development, support, adoption, and use of the Critical Controls [i.5]. See (www.counciloncybersecurity.org). The Critical Security Controls reflect the combined knowledge of actual attacks and effective defences of experts from every part of the cyber security ecosystem. This ensures that the Controls are an effective and specific set of technical measures available to detect, prevent, respond, and mitigate damage from the most common to the most advanced of those attacks.

The Controls are not limited to blocking the initial compromise of systems, but also address detecting already-compromised machines and preventing or disrupting attackers' follow-on actions. The defences identified through these Controls deal with reducing the initial attack surface by hardening device configurations, identifying compromised machines to address long-term threats inside an organization's network, disrupting attackers' command-and-control of 5 implanted malicious code, and establishing an adaptive, continuous defence and response capability that can be maintained and improved. The five critical tenets of an effective cyber defence system as reflected in the Critical Security Controls are:

- **Offense informs defence:** Use knowledge of actual attacks that have compromised systems to provide the foundation to continually learn from these events to build effective, practical defences. Include only those controls that can be shown to stop known real-world attacks.
- **Prioritization:** Invest first in Controls that will provide the greatest risk reduction and protection against the most dangerous threat actors, and that can be feasibly implemented in your computing environment.
- **Metrics:** Establish common metrics to provide a shared language for executives, IT specialists, auditors, and security officials to measure the effectiveness of security measures within an organization so that required adjustments can be identified and implemented quickly.
- **Continuous diagnostics and mitigation:** Carry out continuous measurement to test and validate the effectiveness of current security measures, and to help drive the priority of next steps.
- **Automation:** Automate defences so that organizations can achieve reliable, scalable, and continuous measurements of their adherence to the Controls and related metrics.

Introduction

The evolution of cyber defence is increasingly challenging. Massive data losses, theft of intellectual property, credit card breaches, identity theft, threats to privacy, denial of service - these have become endemic. Access exists to an extraordinary array of security tools and technology, security standards, training and classes, certifications, vulnerability databases, guidance, best practices, catalogues of security controls, and countless security checklists, benchmarks, and recommendations.

But all of this technology, information, and oversight have become a veritable "Fog of More": competing options, priorities, opinions, and claims. The threats have evolved, the actors have become smarter, and users have become more mobile. Data is now distributed across multiple locations, many of which are not within our organization's infrastructure anymore. With more reliance on cloud computing data centres, the data and even applications are becoming more distributed. In a complex, interconnected world, no enterprise can think of its security as a standalone problem, and collective action is nearly impossible.

Focus is needed to establish priority of action, collective support, and keeping knowledge and technology current in the face of rapidly evolving problems and an apparently infinite number of possible solutions. The most critical areas need to be addressed and the first steps taken toward maturing risk management programs. This includes a roadmap of fundamentals, and guidance to measure and improve the implementation defensive steps that have the greatest value. These issues led to, and drive, the Critical Security Controls. The value is determined by knowledge and data - the ability to prevent, alert, and respond to the attacks that are plaguing enterprises today.

The Critical Security Controls and Other Risk Management Approaches

The Critical Security Controls are not a replacement for comprehensive mandatory compliance or regulatory schemes. The Controls instead prioritize and focus on a smaller number of actionable controls with high-payoff.

Although lacking the formality of traditional Risk Management Frameworks, the Critical Security Controls process constitutes a "foundational risk assessment" - one that can be used by an individual enterprise as a starting point for immediate, high-value action, is demonstrably consistent with formal risk management frameworks, and provides a basis for common action across diverse communities (e.g. that might be subject to different regulatory or compliance requirements).

The Critical Security Controls also proactively align with and leverage ongoing work in security standards and best practices. Examples include: the Security Content Automation Program (SCAP) and Special Publication 800-53 [i.1] (Recommended Security Controls for Federal Information Systems and Organizations) sponsored by the National Institute of Standards and Technology (NIST); the Australian Signals Directorate's "Top 35 Strategies to Mitigate Targeted Cyber Intrusions"; and the International Organization for Standardization (ISO)/International Electrotechnical Commission (IEC) 27002:2013 [i.4] Information technology - Security techniques - Code of practice for information security controls. References and mappings to these can be found at www.counciloncybersecurity.org.

Initiating Implementation

Some of the Critical Security Controls, in particular CSC 1 through CSC 5, are foundational, and should be considered as the actions to be taken. This is the approach taken by, for example, the DHS Continuous Diagnostic and Mitigation (CDM) Program.

For a highly focused and direct starting point, five especially useful actions have the most immediate impact on preventing attacks. These actions are specially noted in the Controls listings, and consist of:

- 1) application whitelisting (found in CSC 2);
- 2) use of standard, secure system configurations (found in CSC 3);
- 3) patch application software within 48 hours (found in CSC 4);
- 4) patch system software within 48 hours (found in CSC 4); and
- 5) reduced number of users with administrative privileges (found in CSC 3 and CSC 12).

1 Scope

The present document describes a specific set of technical measures available to detect, prevent, respond, and mitigate damage from the most common to the most advanced of cyber attacks. The measures reflect the combined knowledge of actual attacks and effective defences.

The present document is technically equivalent and compatible with the 5.1 version of the "The Critical Security Controls for Effective Cyber Defence," 10 July 2014, which can be found at the website <http://www.counciloncybersecurity.org/critical-controls/>.

2 References

2.1 Normative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the reference document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at <http://docbox.etsi.org/Reference>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are necessary for the application of the present document.

Not applicable.

2.2 Informative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the reference document (including any amendments) applies.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are not necessary for the application of the present document but they assist the user with regard to a particular subject area.

- [i.1] NIST Special Publication 800-53: "Security and Privacy Controls for Federal Information Systems and Organizations".

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

Critical Security Control (CSC): specified capabilities that reflect the combined knowledge of actual attacks and effective defences of experts that are maintained by the Council on Cybersecurity and found at the website <http://www.counciloncybersecurity.org/critical-controls/>

quick win: actions that can be relatively easily taken with minimal resources that have a significant cyber security benefit

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

802.1x	Institute of Electrical and Electronic Engineers Standard for Port-based Network Access Control
ACK	Acknowledge
ACL	Access Controls List
AES	Advanced Encryption Standard
APT	Advanced Persistent Threat
ASLR	Address Space Layout Randomization
BYOD	Bring Your Own Device
C2	Command and Control
CA	Certificate Authority
CCE™	Common Configuration Enumeration
CD	Compact Disc
CDM	Continuous Diagnostic and Mitigation
CP	Certificate Policy
CPE™	Common Platform Enumeration
CPS	Certificate Practice Statement
CSC	Critical Security Control or Capability
CVE™	Common Vulnerability Enumeration
CVSS	Common Vulnerability Scoring System
DEP	Data Execution Prevention
DHCP	Dynamic Host Configuration Protocol
DHS	Department of Homeland Security
DLL	Dynamic Link Library
DLP	Data Loss Prevention
DMZ	demilitarized zone
DNS	Domain Name system
DVD	Digital Versatile Disc or Digital Video Disc
EAP	Extensible Authentication Protocol
EICAR	European Expert Group for IT-Security
EMET	Enhanced Mitigation Experience Toolkit
FTP	File Transfer Protocol
HSM	Hardware Security Modules
HTTP	Hypertext Transfer Protocol
ICMP	Internet Control Message Protocol
ID	Identifier
IDS	Intrusion Detection System
IEC	International Electrotechnical Commission
IP	Internet protocol
IPS	Intrusion prevention system
IPSEC	Internet Protocol Security
IPv6	Internet Protocol version 6
ISO	International Organization for Standardization
IT	Information technology
LAN	local area network
LDAP	Lightweight Directory Access Protocol

MAC	Media Access Control
NAC	Network Access Control
NICE	National Initiative on Cybersecurity Education
NIST	National Institute of Standards and Technology
NTP	Network Time Protocol
OTP	One Time Password
OVAL®	Open Vulnerability and Assessment Language
OWASP	Open Web Application Security Project
RDP	Remote Desktop Protocol
SANS	SysAdmin, Audit, Networking, and Security
SCADA	Supervisory Control and Data Acquisition
SCAP	Security Content Automation Program
SIEM	Security Information Event Management or Security Incident Event Management
SIM	Subscriber Information Module
SP	Special Publication
SPF	Sender Policy Framework
SQL	Structured Query Language
SSL	Secure Sockets Layer
SYN	synchronize
TCP	transmission control protocol
TLS	Transport Layer Security
URL	Uniform Resource Locator
USB	Universal Serial Bus
UTC	Universal Time Coordinated
VLAN	Virtual Local Area Network
VMS	Vulnerability Management System
VNC	Virtual Channel Network
VPN	Virtual Private Network
WAF	Web Application Firewall
WIDS	Wireless Intrusion Detection System
WPA2	Wi-Fi Protected Access II
XCCDF	Extensible Configuration Checklist
XML	Extensible Markup Language

4 Critical Security Controls

4.0 Structure of the Critical Security Controls Document

The presentation of each Critical Security Control in the present document includes:

- A description of the importance of the Control in blocking or identifying presence of attacks and an explanation of how attackers actively exploit the absence of this control.
- Listing of the specific actions that organizations are taking to implement, automate, and measure effectiveness of this control. The sub-controls are grouped into four categories:
 - Easy actions that provide significant risk reduction without major financial, procedural, architectural, or technical changes to an environment, or that provide such substantial and immediate risk reduction against very common attacks that most security-aware organizations prioritize these key controls.
 - Visibility and attribution measures to improve the process, architecture, and technical capabilities of organizations to monitor their networks and computer systems to detect attack attempts, locate points of entry, identify already-compromised machines, interrupt infiltrated attackers' activities, and gain information about the sources of an attack.
 - Improved information security configuration and hygiene to reduce the number and magnitude of security vulnerabilities and improve the operations of networked computer systems, with a focus on protecting against poor security practices by system administrators and end-users that could give an attacker an advantage.

- Advanced sub-controls that use new technologies or procedures that provide maximum security but are harder to deploy or more expensive or require more highly skilled staff than commoditized security solutions.
- Procedures and tools that enable implementation and automation.
- Metrics and tests to assess implementation status and effectiveness.
- Sample entity relationship diagrams that show components of implementation.

4.1 CSC 1: Inventory of Authorized and Unauthorized Devices

Actively manage (inventory, track, and correct) all hardware devices on the network so that only authorized devices are given access, and unauthorized and unmanaged devices are found and prevented from gaining access.

Why Is This Control Critical?

Attackers, who can be located anywhere in the world, are continuously scanning the address space of target organizations, waiting for new and unprotected systems to be attached to the network. Attackers also look for devices (especially laptops) which come and go off of the enterprise's network, and so get out of synch with patches or security updates. Attacks can take advantage of new hardware that is installed on the network one evening but not configured and patched with appropriate security updates until the following day. Even devices that are not visible from the Internet can be used by attackers who have already gained internal access and are hunting for internal jump points or victims. Additional systems that connect to the enterprise's network (e.g. demonstration systems, temporary test systems, guest networks) should also be managed carefully and/or isolated in order to prevent adversarial access from affecting the security of enterprise operations.

As new technology continues to come out, BYOD (bring your own device) - where employees bring personal devices into work and connect them to the network - is becoming very common. These devices could already be compromised and be used to infect internal resources.

Managed control of all devices also plays a critical role in planning and executing system backup and recovery.

How to Implement This Control

Table 1

ID #	Description	Category
CSC 1-1	Deploy an automated asset inventory discovery tool and use it to build a preliminary asset inventory of systems connected to an organization's public and private network(s). Both active tools that scan through network address ranges and passive tools that identify hosts based on analysing their traffic should be employed.	Quick win
CSC 1-2	Deploy dynamic host configuration protocol (DHCP) server logging, and utilize a system to improve the asset inventory and help detect unknown systems through this DHCP information.	Quick win
CSC 1-3	Ensure that all equipment acquisitions automatically update the inventory system as new, approved devices are connected to the network.	Quick win
CSC 1-4	Maintain an asset inventory of all systems connected to the network and the network devices themselves, recording at least the network addresses, machine name(s), purpose of each system, an asset owner responsible for each device, and the department associated with each device. The inventory should include every system that has an Internet protocol (IP) address on the network, including but not limited to desktops, laptops, servers, network equipment (routers, switches, firewalls, etc.), printers, storage area networks, Voice Over-IP telephones, multi-homed addresses, virtual addresses, etc. The asset inventory created has to include data on whether the device is a portable and/or personal device. Devices such as mobile phones, tablets, laptops, and other portable electronic devices that store or process data have to be identified, regardless of whether they are attached to the organization's network.	Visibility/ Attribution
CSC 1-5	Deploy network level authentication via 802.1x to limit and control which devices can be connected to the network. The 802.1x has to be tied into the inventory data to determine authorized versus unauthorized systems.	Configuration/ Hygiene
CSC 1-6	Deploy network access control (NAC) to monitor authorized systems so if attacks occur, the impact can be remediated by moving the untrusted system to a virtual local area network that has minimal access.	Configuration/Hygiene

ID #	Description	Category
CSC 1-7	Utilize client certificates to validate and authenticate systems prior to connecting to the private network.	Advanced

CSC 1 Procedures and Tools

This Control requires both technical and procedural actions, united in a process that accounts for and manages the inventory of hardware and all associated information throughout its life-cycle. It links to the business by establishing information/asset owners who are responsible for each component of a business process that includes information, software, and hardware. Organizations can use large-scale, comprehensive enterprise products to maintain IT asset inventories. Others use more modest tools to gather the data by sweeping the network, and manage the results separately in a database.

Maintaining a current and accurate view of IT assets is an ongoing and dynamic process. Organizations can actively scan on a regular basis, sending a variety of different packet types to identify devices connected to the network. Before such scanning can take place, organizations should verify that they have adequate bandwidth for such periodic scans by consulting load history and capacities for their networks. In conducting inventory scans, scanning tools could send traditional ping packets (ICMP Echo Request) looking for ping responses to identify a system at a given IP address. Because some systems block inbound ping packets, in addition to traditional pings, scanners can also identify devices on the network using transmission control protocol (TCP) synchronize (SYN) or acknowledge (ACK) packets. Once they have identified IP addresses of devices on the network, some scanners provide robust fingerprinting features to determine the operating system type of the discovered machine.

In addition to active scanning tools that sweep the network, other asset identification tools passively listen on network interfaces looking for devices to announce their presence by sending traffic. Such passive tools can be connected to switch span ports at critical places in the network to view all data flowing through such switches, maximizing the chance of identifying systems communicating through those switches.

Many organizations also pull information from network assets such as switches and routers regarding the machines connected to the network. Using securely authenticated and encrypted network management protocols, tools can retrieve MAC addresses and other information from network devices that can be reconciled with the organization's asset inventory of servers, workstations, laptops, and other devices. Once MAC addresses are confirmed, switches should implement 802.1x and NAC to only allow authorized systems that are properly configured to connect to the network.

Wireless devices (and wired laptops) may periodically join a network and then disappear, making the inventory of currently available systems churn significantly. Likewise, virtual machines can be difficult to track in asset inventories when they are shut down or paused. Additionally, remote machines accessing the network using virtual private network (VPN) technology may appear on the network for a time, and then be disconnected from it. Whether physical or virtual, each machine using an IP address should be included in an organization's asset inventory.

CSC 1 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take to detect new devices added to the organization's network (time in minutes)?
- 2) How long does it take the scanners to alert the organization's administrators that an unauthorized device is on the network (time in minutes)?
- 3) How long does it take to isolate/remove unauthorized devices from the organization's network (time in minutes)?
- 4) Are the scanners able to identify the location, department, and other critical details about the unauthorized system that is detected (yes or no)?

CSC 1 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) How many unauthorized devices are presently on the organization's network (by business unit)?

- 2) How long, on average, does it take to remove unauthorized devices from the organization's network (by business unit)?
- 3) What is the percentage of systems on the organization's network that are not utilizing Network Access Control (NAC) to authenticate to the organization's network (by business unit)?
- 4) What is the percentage of systems on the organization's network that are not utilizing Network Access Control (NAC) with client certificates to authenticate to the organization's network (by business unit)?

CSC 1 Effectiveness Test

To evaluate the implementation of Control 1 on a periodic basis, the evaluation team will connect hardened test systems to at least 10 locations on the network, including a selection of subnets associated with demilitarized zones (DMZs), workstations, and servers. Two of the systems have to be included in the asset inventory database, while the other systems are not. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the newly connected systems within 24 hours of the test machines being connected to the network. The evaluation team has to verify that the system provides details of the location of all the test machines connected to the network. For those test machines included in the asset inventory, the team has to also verify that the system provides information about the asset owner.

CSC 1 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

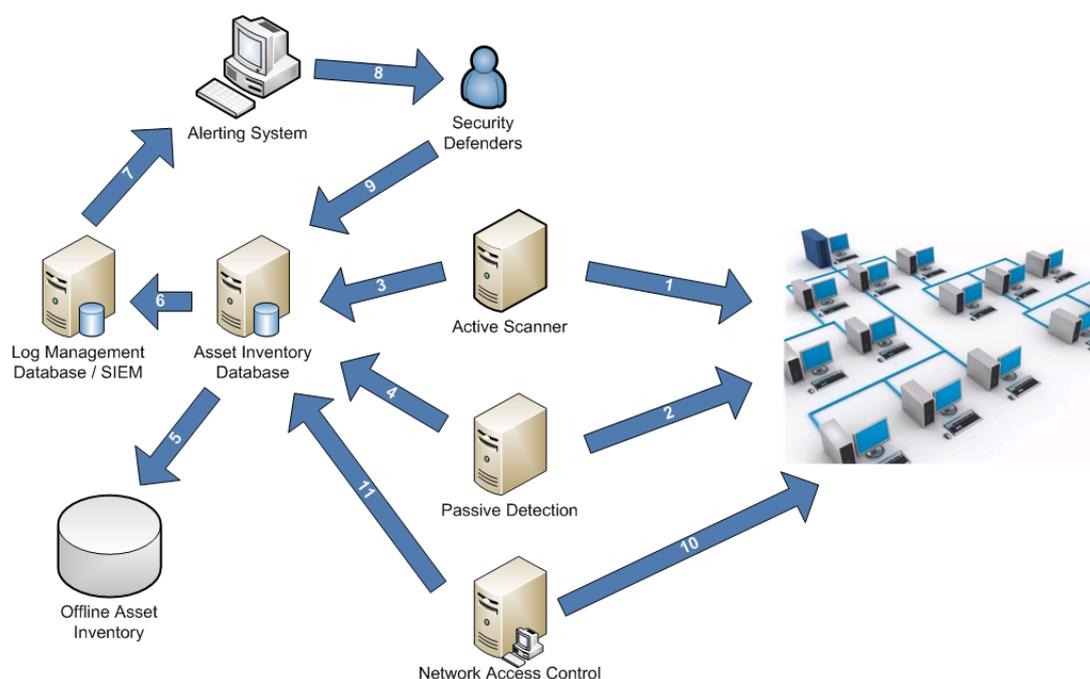

Figure 1

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining hardware devices on the organization's network. These systems should be able to identify if new systems are introduced into the environment that have not been authorized by enterprise personnel. The following list of the steps in figure 1 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Active device scanner scans network systems.
- Step 2: Passive device scanner captures system information.
- Step 3: Active scanner reports to inventory database.

- Step 4: Passive scanner reports to inventory database.
- Step 5: Inventory database stored offline.
- Step 6: Inventory database initiates alert system.
- Step 7: Alert system notifies security defenders.
- Step 8: Security defenders monitor and secure inventory database.
- Step 9: Security defenders update secure inventory database.
- Step 10: Network access control continuously monitors network.
- Step 11: Network access control checks and provides updates to the asset inventory database.

4.2 CSC 2: Inventory of Authorized and Unauthorized Software

Actively manage (inventory, track, and correct) all software on the network so that only authorized software is installed and can execute, and that unauthorized and unmanaged software is found and prevented from installation or execution.

Why Is This Control Critical?

Attackers continuously scan target organizations looking for vulnerable versions of software that can be remotely exploited. Some attackers also distribute hostile web pages, document files, media files, and other content via their own web pages or otherwise trustworthy third-party sites. When unsuspecting victims access this content with a vulnerable browser or other client-side program, attackers compromise their machines, often installing backdoor programs and bots that give the attacker long-term control of the system. Some sophisticated attackers may use zero-day exploits, which take advantage of previously unknown vulnerabilities for which no patch has yet been released by the software vendor. Without proper knowledge or control of the software deployed in an organization, defenders cannot properly secure their assets.

Poorly controlled machines are more likely to be either running software that is unneeded for business purposes, introducing potential security flaws, or running malware introduced by an attacker after a system is compromised. Once a single machine has been exploited, attackers often use it as a staging point for collecting sensitive information from the compromised system and from other systems connected to it. In addition, compromised machines are used as a launching point for movement throughout the network and partnering networks. In this way, attackers may quickly turn one compromised machine into many. Organizations that do not have complete software inventories are unable to find systems running vulnerable or malicious software to mitigate problems or root out attackers.

Managed control of all software also plays a critical role in planning and executing system backup and recovery.

How to Implement This Control

Table 2

ID #	Description	Category
CSC 2-1	Deploy application whitelisting technology that allows systems to run software only if it is included on the whitelist and prevents execution of all other software on the system. The whitelist may be very extensive (as is available from commercial whitelist vendors), so that users are not inconvenienced when using common software. Or, for some special-purpose systems (which require only a small number of programs to achieve their needed business functionality), the whitelist may be quite narrow. When protecting systems with customized software that may be seen as difficult to whitelist, use item 8 below (isolating the custom software in a virtual operating system that does not retain infections).	<i>Quick win (One of the "First Five")</i>
CSC 2-2	Devise a list of authorized software and version that is required in the enterprise for each type of system, including servers, workstations, and laptops of various kinds and uses. This list should be monitored by file integrity checking tools to validate that the authorized software has not been modified.	Quick win

ID #	Description	Category
CSC 2-3	Perform regular scanning for unauthorized software and generate alerts when it is discovered on a system. A strict change-control process should also be implemented to control any changes or installation of software to any systems on the network. This includes alerting when unrecognized binaries (executable files, DLL's and other libraries, etc.) are found on a system, even inside of compressed archives. This includes checking for unrecognized or altered versions of software by comparing file hash values (attackers often utilize altered versions of known software to perpetrate attacks, and file hash comparisons will reveal the compromised software components).	Quick win
CSC 2-4	Deploy software inventory tools throughout the organization covering each of the operating system types in use, including servers, workstations, and laptops. The software inventory system should track the version of the underlying operating system as well as the applications installed on it. Furthermore, the tool should record not only the type of software installed on each system, but also its version number and patch level.	Visibility/ Attribution
CSC 2-5	The software inventory systems have to be integrated with the hardware asset inventory so that all devices and associated software are tracked from a single location.	Visibility/ Attribution
CSC 2-6	Dangerous file types (e.g. .exe, .zip, .msi) should be closely monitored and/or blocked.	Configuration/ Hygiene
CSC 2-7	Virtual machines and/or air-gapped systems should be used to isolate and run applications that are required for business operations but based on higher risk should not be installed within a networked environment.	Advanced
CSC 2-8	Configure client workstations with non-persistent, virtualized operating environments that can be quickly and easily restored to a trusted snapshot on a periodic basis.	Advanced
CSC 2-9	Deploy software that only provides signed software ID tags. A software identification tag is an XML file that is installed alongside software and uniquely identifies the software, providing data for software inventory and asset management.	Advanced

CSC 2 Procedures and Tools

Whitelisting can be implemented using commercial whitelisting tools or application execution tools that come with anti-virus suites and with Windows®. Commercial software and asset inventory tools are widely available and in use in many enterprises today. The best of these tools provide an inventory check of hundreds of common applications used in enterprises, pulling information about the patch level of each installed program to ensure that it is the latest version and leveraging standardized application names, such as those found in the common platform enumeration specification.

Features that implement whitelists of programs allowed to run are included in many modern endpoint security suites. Moreover, commercial solutions are increasingly bundling together anti-virus, anti-spyware, personal firewall, and host-based intrusion detection systems (IDS) and intrusion prevention systems (IPS), along with application white and black listing. In particular, most endpoint security solutions can look at the name, file system location, and/or cryptographic hash of a given executable to determine whether the application should be allowed to run on the protected machine. The most effective of these tools offer custom whitelists based on executable path, hash, or regular expression matching. Some even include a gray list function that allows administrators to define rules for execution of specific programs only by certain users and at certain times of day.

CSC 2 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take to detect new software installed on systems in the organization (time in minutes)?
- 2) How long does it take the scanners to alert the organization's administrators that an unauthorized software application is on a system (time in minutes)?
- 3) How long does it take to alert that a new software application has been discovered (time in minutes)?

Are the scanners able to identify the location, department, and other critical details about the unauthorized software that is detected (yes or no)?

CSC 2 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) How many unauthorized software applications are presently located on business systems within the organization (by business unit)?
- 2) How long, on average, does it take to remove unauthorized applications from business systems within the organization (by business unit)?
- 3) What is the percentage of the organization's business systems that are not running software whitelisting software that blocks unauthorized software applications (by business unit)?

How many software applications have been recently blocked from executing by the organization's software whitelisting software (by business unit)?

CSC 2 Effectiveness Test

To evaluate the implementation of Control 2 on a periodic basis, the evaluation team has to move a benign software test program that is not included in the authorized software list to 10 systems on the network. Two of the systems have to be included in the asset inventory database, while the other systems do not need to be included. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the new software within 24 hours. The team has to also verify that the alert or e-mail is received within one additional hour indicating that the software has been blocked or quarantined. The evaluation team has to verify that the system provides details of the location of each machine with this new test software, including information about the asset owner. The evaluation team has to then verify that the software is blocked by attempting to execute it and verifying that the software is not allowed to run.

On systems where blocking is not allowed or blocking functionality is not available, the team has to verify that the execution of unauthorized software is detected and results in a notification to alert the security team that unauthorized software is being used.

CSC 2 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

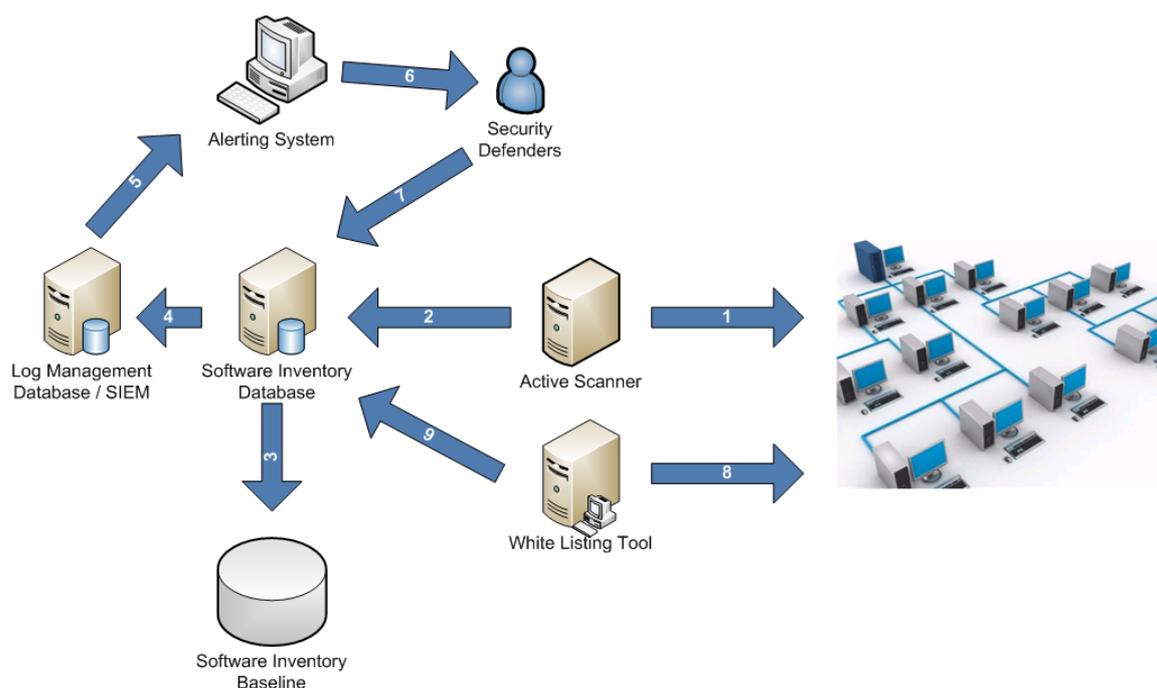

Figure 2

A control system is a device or set of devices to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining software installed on the organization's network systems. These systems should be able to identify if new software is introduced to the environment that has not been authorized by enterprise personnel. The following list of the steps in figure 2 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Active device scanner.
- Step 2: Active scanner reports to inventory database.
- Step 3: Inventory database compares to inventory baseline.
- Step 4: Inventory database initiates alerting system.
- Step 5: Alert system notifies security defenders.
- Step 6: Security defenders monitor and secure inventory database.
- Step 7: Security defenders update software inventory database.
- Step 8: Whitelisting tool continuously monitors all systems on the network.
- Step 9: Whitelisting checks and makes updates to the software inventory database.

4.3 CSC 3: Secure Configurations for Hardware and Software on Mobile Devices, Laptops, Workstations, and Servers

Establish, implement, and actively manage (track, report on, correct) the security configuration of laptops, servers, and workstations using a rigorous configuration management and change control process in order to prevent attackers from exploiting vulnerable services and settings.

Why Is This Control Critical?

As delivered by manufacturers and resellers, the default configurations for operating systems and applications are normally geared to ease-of-deployment and ease-of-use - not security. Basic controls, open services and ports, default accounts or passwords, older (vulnerable) protocols, pre-installation of unneeded software; all can be exploitable in their default state.

Developing configuration settings with good security properties is a complex task beyond the ability of individual users, requiring analysis of potentially hundreds or thousands of options in order to make good choices. Even if a strong initial configuration is developed and installed, it has to be continually managed to avoid security "decay" as software is updated or patched, new security vulnerabilities are reported, and configurations are "tweaked" to allow the installation of new software or support new operational requirements. If not, attackers will find opportunities to exploit both network-accessible services and client software.

How to Implement This Control

Table 3

ID #	Description	Category
CSC 3-1	Establish and ensure the use of standard secure configurations of your operating systems. Standardized images should represent hardened versions of the underlying operating system and the applications installed on the system. Hardening typically includes: removal of unnecessary accounts (including service accounts), disabling or removal of unnecessary services, configuring non-executable stacks and heaps, applying patches, closing open and unused network ports, implementing intrusion detection systems and/or intrusion prevention systems, and use of host-based firewalls. These images should be validated and refreshed on a regular basis to update their security configuration in light of recent vulnerabilities and attack vectors.	Quick win (One of the "First Five")
CSC 3-2	Implement automated patching tools and processes for both applications and for operating system software. When outdated systems can no longer be patched, update to the latest version of application software. Remove outdated, older, and unused software from the system.	Quick win (One of the "First Five")

ID #	Description	Category
CSC 3-3	Limit administrative privileges to very few users who have both the knowledge necessary to administer the operating system and a business need to modify the configuration of the underlying operating system. This will help prevent installation of unauthorized software and other abuses of administrator privileges.	<i>Quick win (One of the "First Five")</i>
CSC 3-4	Follow strict configuration management, building a secure image that is used to build all new systems that are deployed in the enterprise. Any existing system that becomes compromised should be re-imaged with the secure build. Regular updates or exceptions to this image should be integrated into the organization's change management processes. Images should be created for workstations, servers, and other system types used by the organization.	<i>Quick win</i>
CSC 3-5	Store the master images on securely configured servers, validated with integrity checking tools capable of continuous inspection, and change management to ensure that only authorized changes to the images are possible. Alternatively, these master images can be stored in offline machines, air-gapped from the production network, with images copied via secure media to move them between the image storage servers and the production network.	<i>Quick win</i>
CSC 3-6	Negotiate contracts to buy systems configured securely out of the box using standardized images, which should be devised to avoid extraneous software that would increase their attack surface and susceptibility to vulnerabilities.	<i>Visibility/ Attribution</i>
CSC 3-7	Do all remote administration of servers, workstation, network devices, and similar equipment over secure channels. Protocols such as telnet, VNC, RDP, or others that do not actively support strong encryption should only be used if they are performed over a secondary encryption channel, such as SSL or IPSEC.	<i>Configuration/Hygiene</i>
CSC 3-8	Utilize file integrity checking tools to ensure that critical system files (including sensitive system and application executables, libraries, and configurations) have not been altered. All alterations to such files should be automatically reported to security personnel. The reporting system should have the ability to account for routine and expected changes, highlighting unusual or unexpected alterations. For investigative support, the reporting system should be able to show the history of configuration changes over time and identify who made the change (including the original logged-in account in the event of a user ID switch, such as with the su or sudo command). These integrity checks should also identify suspicious system alterations such as owner and permissions changes to files or directories; the use of alternate data streams which could be used to hide malicious activities; as well as detecting the introduction of extra files into key system areas (which could indicate malicious payloads left by attackers or additional files inappropriately added during batch distribution processes).	<i>Configuration/Hygiene</i>
CSC 3-9	Implement and test an automated configuration monitoring system that measures all secure configuration elements that can be measured through remote testing using features such as those included with tools compliant with Security Content Automation Protocol (SCAP), and alerts when unauthorized changes occur. This includes detecting new listening ports, new administrative users, changes to group and local policy objects, (where applicable), and new services running on a system.	<i>Advanced</i>
CSC 3-10	Deploy system configuration management tools, such as Active Directory Group Policy Objects for Microsoft Windows® systems or Puppet for Unix® systems that will automatically enforce and redeploy configuration settings to systems at regularly scheduled intervals. They should be capable of triggering redeployment of configuration settings on a scheduled, manual, or event-driven basis.	<i>Configuration/Hygiene</i>

CSC 3 Procedures and Tools

Rather than start from scratch developing a security baseline for each software system, organizations should start from publicly developed, vetted, and supported security benchmarks, security guides, or checklists. Excellent resources include:

- The Centre for Internet Security Benchmarks Program (www.cisecurity.org).
- The NIST National Checklist Program (<https://web.nvd.nist.gov/view/ncp/repository>).

Organizations should augment or adjust these baselines to satisfy local policies and requirements, but deviations and rationale should be documented to facilitate later reviews or audits.

For a complex enterprise, the establishment of a single security baseline configuration (for example, a single installation image for all workstations across the entire enterprise) is sometimes not practical or deemed unacceptable. It is likely that you will need to support different standardized images, based on the proper hardening to address risks and needed functionality of the intended deployment.

EXAMPLE: A web server in the DMZ vs. an email or other application server in the internal network.

The number of variations should be kept to a minimum in order to better understand and manage the security properties of each, but organizations then have to be prepared to manage multiple baselines.

Commercial and/or free configuration management tools can then be employed to measure the settings of operating systems and applications of managed machines to look for deviations from the standard image configurations. Typical configuration management tools use some combination of: an agent installed on each managed system, or agentless inspection of systems by remotely logging in to each managed machine using administrator credentials. Additionally, a hybrid approach is sometimes used whereby a remote session is initiated, a temporary or dynamic agent is deployed on the target system for the scan, and then the agent is removed.

CSC 3 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take to detect configuration changes to a network system (time in minutes)?
- 2) How long does it take the scanners to alert the organization's administrators that an unauthorized configuration change has occurred (time in minutes)?
- 3) How long does it take to block/quarantine unauthorized changes on network systems (time in minutes)?
- 4) Are the scanners able to identify the location, department, and other critical details about the systems where unauthorized changes occurred (yes or no)?
- 5) Are the scanners able to trigger different notifications/workflows based on the severity of the configuration variance detected?

For all of the above, consider that system priority, service level commitments, system role, and other factors may drive varying objectives for scan frequency and alert time frames on different systems. Ensure that the rationale for these classifications is clear, consistent, documented, and consistently applied. Verify that target detection and notification results are aligned with service level commitments and policies for each class of system.

CSC 3 Automation Metrics

In order to automate the collection of relevant data from these systems, the organization should gather the following information with automated technical sensors:

- 1) What is the percentage of business systems that are not currently configured with a security configuration that matches the organization's approved configuration standard (by business unit)?
- 2) What is the percentage of business systems whose security configuration is not enforced by the organization's technical configuration management applications (by business unit)?
- 3) What is the percentage of business systems that are not up to date with the latest available operating system software security patches (by business unit)?
- 4) What is the percentage of business systems that are not up to date with the latest available business software application security patches (by business unit)?
- 5) What is the percentage of business systems not protected by file integrity assessment software applications (by business unit)?
- 6) What is the percentage of unauthorized or undocumented changes with security impact (by business unit)?

CSC 3 Effectiveness Test

To evaluate the implementation of Control 3 on a periodic basis, an evaluation team has to move a benign test system that does not contain the official hardened image, but that does contain additional services, ports, and configuration file changes, onto the network. This has to be performed on 10 different random segments using either real or virtual systems. The evaluation team has to then verify that the systems generate an alert regarding the changes to the software within the target service window, or within 24 hours - whichever is less. It is important that the evaluation team verify that all unauthorized changes have been detected. The team has to also verify that the alert or e-mail is received within one additional hour indicating that the software has been blocked or quarantined. The evaluation team has to verify that the system provides details of the location of each machine with the unauthorized changes, including information about the asset owner.

The evaluation team has to also introduce undocumented/out-of-band configuration settings and binaries using real or virtual systems on 10 random segments. The test should include making a non-persistent change, in which a change is introduced to the primary program location (/bin, Program Files, etc.), left in place for 30-60 minutes, then reverted to the original configuration.

The evaluation team has to verify that all configuration changes and binaries are detected, and that there is a record of the non-persistent changes mentioned above. The detection data should include the nature of the change made (addition, removal, alteration, owner, permissions, contents, etc.), as well as the user account that made the change.

The evaluation team has to also verify that unauthorized software is blocked by attempting to execute it and verifying that it is not allowed to run. On systems where blocking is not allowed or blocking functionality is not available, the team has to verify that the execution of unauthorized software is detected and results in a notification to alert the security team that unauthorized software is being used.

In addition to these tests, the following tests have to be performed:

- 1) File integrity checking tools have to be run on a regular basis. Any changes to critical operating system, services, and configuration files have to be checked on an hourly basis. Any changes have to be detected and either blocked or trigger an alert that follows the above notification process.
- 2) Detection software has to detect the disabling of system logging, as well as the truncation, modification or deletion of log files. Note that growth of logs should not trigger notifications, but suspicious changes associated with malicious activities should; examples include deletion or truncation of logs, modification of past log events, owner or permission changes, etc. Any inappropriate changes to logs have to trigger an alert that follows the above notification process.
- 3) System scanning tools that check for software version, patch levels, and configuration files have to be run on a daily basis. Any changes have to be detected and either blocked or trigger an alert that follows the above notification process.

CSC 3 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur. As with any configurations, all changes have to be approved and managed by a change control process.

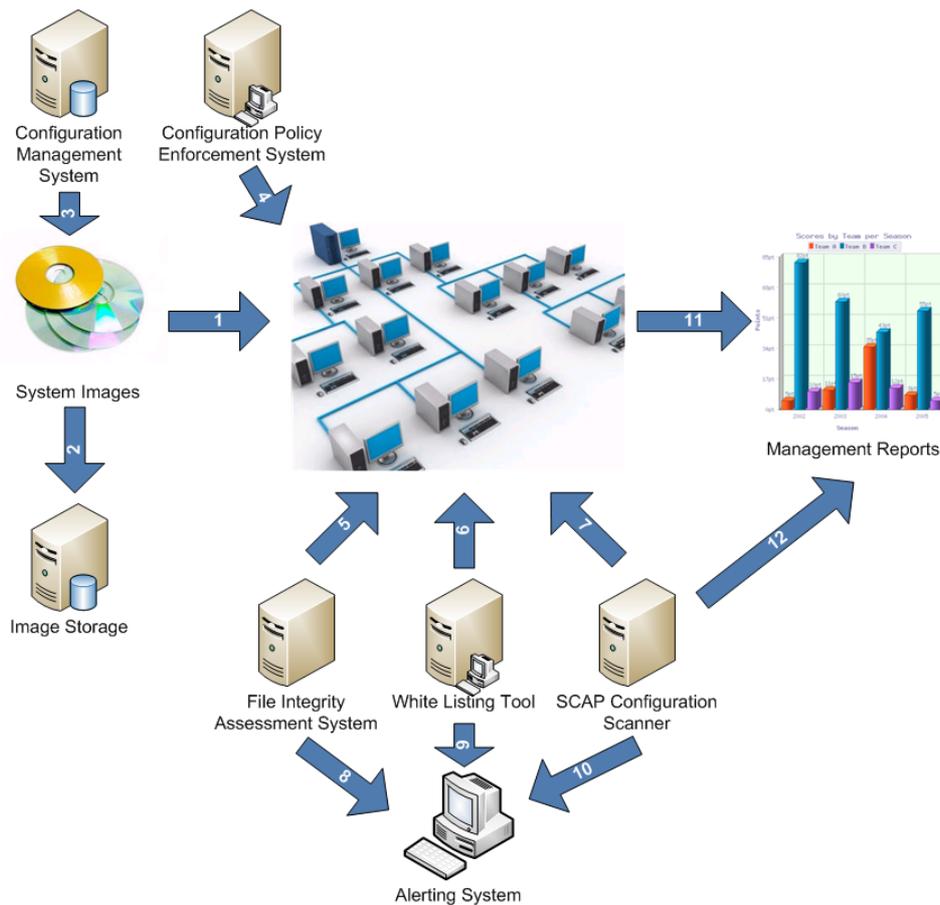

Figure 3

A control system is a device or set of devices to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the devices, software, and entities used to manage and implement consistent configuration settings to workstations, laptops, and servers on the network. The following list of the steps in figure 3 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Secured system images applied to computer systems.
- Step 2: Secured system images stored in a secure manner.
- Step 3: Configuration management system validates and checks system images.
- Step 4: Configuration policy enforcement system actively scans production systems for misconfigurations or deviations from baselines.
- Step 5: File integrity assessment systems monitor critical system binaries and data sets.
- Step 6: Whitelisting tool monitors systems configurations and software.
- Step 7: SCAP configuration scanner validates configurations.
- Step 8: File integrity assessment system sends deviations to alerting system.
- Step 9: Whitelisting tool sends deviations to alerting system.
- Step 10: SCAP configuration scanner sends deviations to alerting system.
- Step 11 and 12: Management reports document configuration status.

4.4 CSC 4: Continuous Vulnerability Assessment and Remediation

Continuously acquire, assess, and take action on new information in order to identify vulnerabilities, remediate, and minimize the window of opportunity for attackers.

Why Is This Control Critical?

Cyber defenders have to operate in a constant stream of new information: software updates, patches, security advisories, threat bulletins, etc. Understanding and managing vulnerabilities has become a continuous activity, requiring significant time, attention, and resources.

Attackers have access to the same information, and can take advantage of gaps between the appearance of new knowledge and remediation.

EXAMPLE: When new vulnerabilities are reported by researchers, a race starts among all parties, including: attackers (to "weaponize", deploy an attack, exploit); vendors (to develop, deploy patches or signatures and updates), and defenders (to assess risk, regression-test patches, install).

Organizations that do not scan for vulnerabilities and proactively address discovered flaws face a significant likelihood of having their computer systems compromised. Defenders face particular challenges in scaling remediation across an entire enterprise, and prioritizing actions with conflicting priorities, and sometimes-uncertain side effects.

How to Implement This Control

Table 4

ID #	Description	Category
CSC 4-1	Run automated vulnerability scanning tools against all systems on the network on a weekly or more frequent basis and deliver prioritized lists of the most critical vulnerabilities to each responsible system administrator along with risk scores that compare the effectiveness of system administrators and departments in reducing risk. Use a SCAP-validated vulnerability scanner that looks for both code-based vulnerabilities (such as those described by Common Vulnerabilities and Exposures entries) and configuration-based vulnerabilities (as enumerated by the Common Configuration Enumeration Project).	<i>Quick win (Supports the "First Five")</i>
CSC 4-2	Correlate event logs with information from vulnerability scans to fulfil two goals. First, personnel should verify that the activity of the regular vulnerability scanning tools themselves is logged. Second, personnel should be able to correlate attack detection events with earlier vulnerability scanning results to determine whether the given exploit was used against a target known to be vulnerable.	<i>Quick win</i>
CSC 4-3	Perform vulnerability scanning in authenticated mode either with agents running locally on each end system to analyze the security configuration or with remote scanners that are given administrative rights on the system being tested. Use a dedicated account for authenticated vulnerability scans, which should not be used for any other administrative activities and should be tied to specific machines at specific IP addresses. Ensure that only authorized employees have access to the vulnerability management user interface and that roles are applied to each user.	<i>Quick win</i>
CSC 4-4	Subscribe to vulnerability intelligence services in order to stay aware of emerging exposures, and use the information gained from this subscription to update the organization's vulnerability scanning activities on at least a monthly basis. Alternatively, ensure that the vulnerability scanning tools you use are regularly updated with all relevant important security vulnerabilities.	<i>Quick win</i>
CSC 4-5	Deploy automated patch management tools and software update tools for operating system and software/applications on all systems for which such tools are available and safe. Patches should be applied to all systems, even systems that are properly air gapped.	<i>Visibility/ Attribution</i>
CSC 4-6	Carefully monitor logs associated with any scanning activity and associated administrator accounts to ensure that all scanning activity and associated access via the privileged account is limited to the timeframes of legitimate scans.	<i>Visibility/ Attribution</i>

ID #	Description	Category
CSC 4-7	Compare the results from back-to-back vulnerability scans to verify that vulnerabilities were addressed either by patching, implementing a compensating control, or documenting and accepting a reasonable business risk. Such acceptance of business risks for existing vulnerabilities should be periodically reviewed to determine if newer compensating controls or subsequent patches can address vulnerabilities that were previously accepted, or if conditions have changed, increasing the risk.	<i>Configuration/Hygiene</i>
CSC 4-8	Measure the delay in patching new vulnerabilities and ensure that the delay is equal to or less than the benchmarks set forth by the organization. Alternative countermeasures should be considered if patches are not available.	<i>Configuration/Hygiene</i>
CSC 4-9	Evaluate critical patches in a test environment before pushing them into production on enterprise systems. If such patches break critical business applications on test machines, the organization has to devise other mitigating controls that block exploitation on systems where the patch cannot be deployed because of its impact on business functionality.	<i>Configuration/Hygiene</i>
CSC 4-10	Establish a process to risk-rate vulnerabilities based on the exploitability and potential impact of the vulnerability, and segmented by appropriate groups of assets (example, DMZ servers, internal network servers, desktops, laptops). Apply patches for the riskiest vulnerabilities first. A phased rollout can be used to minimize the impact to the organization. Establish expected patching timelines based on the risk rating level.	<i>Configuration/Hygiene</i>

CSC 4 Procedures and Tools

A large number of vulnerability scanning tools are available to evaluate the security configuration of systems. Some enterprises have also found commercial services using remotely managed scanning appliances to be effective. To help standardize the definitions of discovered vulnerabilities in multiple departments of an organization or even across organizations, it is preferable to use vulnerability scanning tools that measure security flaws and map them to vulnerabilities and issues categorized using one or more of the following industry-recognized vulnerability, configuration, and platform classification schemes and languages: CVETM, CCETM, OVAL®, CPETM, CVSS, and/or XCCDF.

Advanced vulnerability scanning tools can be configured with user credentials to log in to scanned systems and perform more comprehensive scans than can be achieved without login credentials. The frequency of scanning activities, however, should increase as the diversity of an organization's systems increases to account for the varying patch cycles of each vendor.

In addition to the scanning tools that check for vulnerabilities and misconfigurations across the network, various free and commercial tools can evaluate security settings and configurations of local machines on which they are installed. Such tools can provide fine-grained insight into unauthorized changes in configuration or the inadvertent introduction of security weaknesses by administrators.

Effective organizations link their vulnerability scanners with problem-ticketing systems that automatically monitor and report progress on fixing problems, and that make unmitigated critical vulnerabilities visible to higher levels of management to ensure the problems are solved.

The most effective vulnerability scanning tools compare the results of the current scan with previous scans to determine how the vulnerabilities in the environment have changed over time. Security personnel use these features to conduct vulnerability trending from month to month.

As vulnerabilities related to unpatched systems are discovered by scanning tools, security personnel should determine and document the amount of time that elapses between the public release of a patch for the system and the occurrence of the vulnerability scan. If this time window exceeds the organization's benchmarks for deployment of the given patch's criticality level, security personnel should note the delay and determine if a deviation was formally documented for the system and its patch. If not, the security team should work with management to improve the patching process.

Additionally, some automated patching tools may not detect or install certain patches due to an error by the vendor or administrator. Because of this, all patch checks should reconcile system patches with a list of patches each vendor has announced on its website.

CSC 4 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take vulnerability scanning systems, if they detect unauthorized devices on the network, to generate an alert (time in minutes)?
- 2) How long after a scan successfully completes does it take to generate an alert indicating that it completed (time in minutes)?
- 3) If a scan does not complete, how long does it take to generate an alert that the scan failed to run (time in minutes)?
- 4) How long does it take automated patch management tools to alert or send e-mail to administrative personnel regarding the successful installation of new patches (time in minutes)?

For all of the above, consider that system priority, service level commitments, system role, and other factors may drive varying objectives for scan frequency and alert time frames on different systems. Ensure that the rationale for these classifications is clear, consistent, documented, and consistently applied. Verify that target detection and notification results are aligned with service level commitments and policies for each class of system.

CSC 4 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What is the percentage of the organization's business systems that have not recently been scanned by the organization's approval, SCAP compliant, vulnerability management system (by business unit)?
- 2) What is the average SCAP vulnerability score of each of the organization's business systems (by business unit)?
- 3) What is the total SCAP vulnerability score of each of the organization's business systems (by business unit)?
- 4) How long does it take, on average, to completely deploy operating system software updates to a business system (by business unit)?
- 5) How long does it take, on average, to completely deploy application software updates to a business system (by business unit)?

CSC 4 Effectiveness Test

To evaluate the implementation of Control 4 on a periodic basis, the evaluation team has to verify that scanning tools have successfully completed their weekly or daily scans for the previous 30 cycles of scanning by reviewing archived alerts and reports to ensure that the scan was completed. If a scan could not be completed in that timeframe, the evaluation team has to verify that an alert or e-mail was generated indicating that the scan did not finish.

CSC 4 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

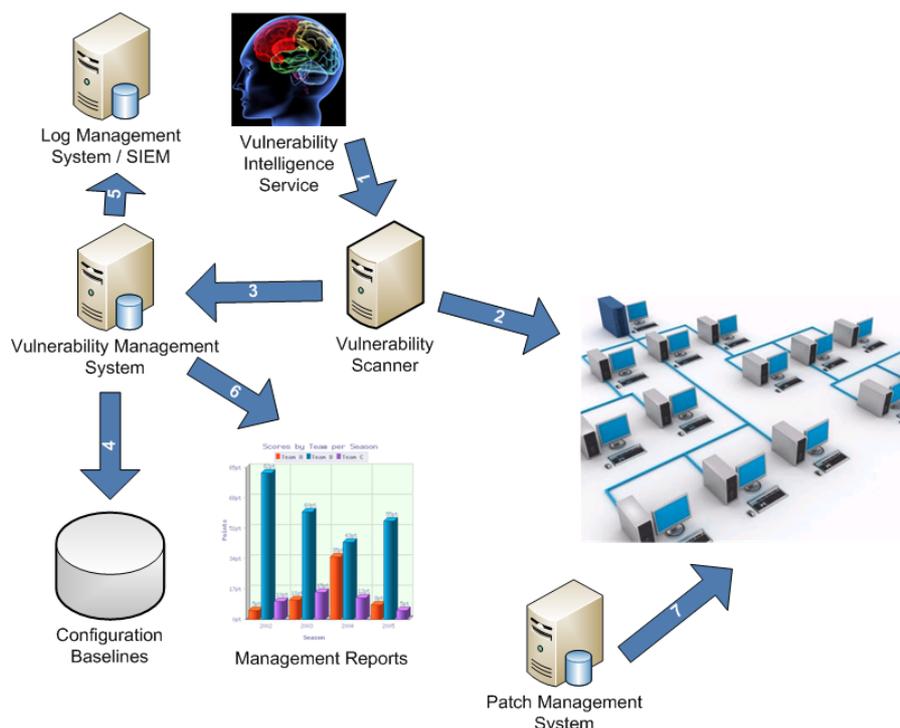

Figure 4

A control system is a device or set of devices to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, the vulnerability scanners, management system, patch management systems, and configuration baselines all work together to address an organization's vulnerability management and remediation strategy. The following list of the steps in figure 4 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Vulnerability intelligence service provides inputs to vulnerability scanner.
- Step 2: Vulnerability scanners scan production systems.
- Step 3: Vulnerability scanners report detected vulnerabilities to a vulnerability management system (VMS).
- Step 4: The VMS compares production systems to configuration baselines.
- Step 5: The VMS sends information to log management correlation system.
- Step 6: The VMS produces reports for management.
- Step 7: A patch management system applies software updates to production systems.

4.5 CSC 5: Malware Defences

Control the installation, spread, and execution of malicious code at multiple points in the enterprise, while optimizing the use of automation to enable rapid updating of defence, data gathering, and corrective action.

Why Is This Control Critical?

Malicious software is an integral and dangerous aspect of Internet threats, and can be designed to attack your systems, devices, or your data. It can be fast-moving, fast-changing, and enter through any number of points like end-user devices, e-mail attachments, web pages, cloud services, user actions, and removable media. Modern malware can be designed to avoid defences, or to attack or disable them.

How to Implement This Control

Malware defences have to be able to operate in this dynamic environment through large-scale automation, rapid updating, and integration with processes like Incident Response. They have to also be deployed at multiple possible points-of-attack to detect, stop the movement of, or control the execution of malicious software. Enterprise endpoint security suites provide administrative features to verify that all defences are active and current on every managed system.

Table 5

ID #	Description	Category
CSC 5-1	Employ automated tools to continuously monitor workstations, servers, and mobile devices with anti-virus, anti-spyware, personal firewalls, and host-based IPS functionality. All malware detection events should be sent to enterprise anti-malware administration tools and event log servers.	<i>Quick win</i>
CSC 5-2	Employ anti-malware software that offers a remote, cloud-based centralized infrastructure that compiles information on file reputations or have administrators manually push updates to all machines. After applying an update, automated systems should verify that each system has received its signature update.	<i>Quick win</i>
CSC 5-3	Configure laptops, workstations, and servers so that they will not auto-run content from removable media, like USB tokens (i.e. "thumb drives"), USB hard drives, CDs/DVDs, FireWire devices, external serial advanced technology attachment devices, and mounted network shares.	<i>Quick win</i>
CSC 5-4	Configure systems so that they automatically conduct an anti-malware scan of removable media when inserted.	<i>Quick win</i>
CSC 5-5	Scan and block all e-mail attachments entering the organization's e-mail gateway if they contain malicious code or file types that are unnecessary for the organization's business. This scanning should be done before the e-mail is placed in the user's inbox. This includes e-mail content filtering and web content filtering.	<i>Quick win</i>
CSC 5-6	Enable anti-exploitation features such as Data Execution Prevention (DEP), Address Space Layout Randomization (ASLR), virtualization/containerization, etc. For increased protection, deploy capabilities such as Enhanced Mitigation Experience Toolkit (EMET) that can be configured to apply these protections to a broader set of applications and executables.	<i>Quick win</i>
CSC 5-7	Limit use of external devices to those that have a business need. Monitor for use and attempted use of external devices.	<i>Quick win</i>
CSC 5-8	Ensure that automated monitoring tools use behaviour-based anomaly detection to complement traditional signature-based detection.	<i>Visibility/ Attribution</i>
CSC 5-9	Use network-based anti-malware tools to identify executables in all network traffic and use techniques other than signature-based detection to identify and filter out malicious content before it arrives at the endpoint.	<i>Visibility/ Attribution</i>
CSC 5-10	Implement an incident response process that allows the IT support organization to supply the security team with samples of malware running on corporate systems that do not appear to be recognized by the enterprise's anti-malware software. Samples should be provided to the security vendor for "out-of-band" signature creation and later deployed to the enterprise by system administrators.	<i>Advanced</i>
CSC 5-11	Enable domain name system (DNS) query logging to detect hostname lookup for known malicious C2 domains.	<i>Advanced</i>

CSC 5 Procedures and Tools

To ensure anti-virus signatures are up to date, organizations use automation. They use the built-in administrative features of enterprise endpoint security suites to verify that anti-virus, anti-spyware, and host-based IDS features are active on every managed system. They run automated assessments daily and review the results to find and mitigate systems that have deactivated such protections, as well as systems that do not have the latest malware definitions.

Some enterprises deploy free or commercial honeypot and "tarpit" tools to identify attackers in their environment. Security personnel should continuously monitor these tools to determine whether traffic is directed to them and account logins are attempted. When they identify such events, these personnel should gather the source address from which this traffic originates and other details associated with the attack for follow-on investigation.

CSC 5 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take the system to identify any malicious software that is installed, attempted to be installed, executed, or attempted to be executed on a computer system (time in minutes)?
- 2) How long does it take the system to send e-mail notification to a list of enterprise personnel via their centralized anti-malware console or event log system after malicious code has been identified (time in minutes)?
- 3) Does the system have the ability to block installation, prevent execution, or quarantine malicious software (yes or no)?
- 4) Does the system have the ability to identify the business unit in the organization where the malicious software was identified (yes or no)?

How long does it take the organization to completely remove the malicious code from the system after it has been identified (time in minutes)?

CSC 5 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) How many instances of malicious code have been detected within a period of time by host based anti-malware systems (by business unit)?
- 2) How many instances of malicious code that were detected within a period of time were automatically remediated by the organization's host based anti-malware systems (by business unit)?
- 3) How many instances of malicious code have been detected within a period of time by network based anti-malware systems (by business unit)?
- 4) How many instances of malicious code that were detected within a period of time were automatically remediated by the organization's network based anti-malware systems (by business unit)?
- 5) Percentage of applications on a system that are not utilizing application sandboxing products (by business unit)?

Percentage of systems with anti-malware systems deployed, enabled, and up-to-date (by business unit)?

CSC 5 Effectiveness Test

To evaluate the implementation of Control 5 on a periodic basis, the evaluation team has to move a benign software test program that appears to be malware (such as an EICAR file or benign hacker tools), but that is not included in the official authorized software list, to 10 systems on the network via a network share. The selection of these systems has to be as random as possible and include a cross-section of the organization's systems and locations. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the benign malware within one hour. The team has to also verify that the alert or e-mail indicating that the software has been blocked or quarantined is received within one hour. The evaluation team has to verify that the system provides details of the location of each machine with this new test file, including information about the asset owner. The team has to then verify that the file is blocked by attempting to execute or open it and verifying that it is not allowed to be accessed.

Once this test has been performed transferring the files to organization systems via removable media, the same test has to be repeated, but this time transferring the benign malware to 10 systems via e-mail instead. The organization has to expect the same notification results as noted with the removable media test.

CSC 5 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

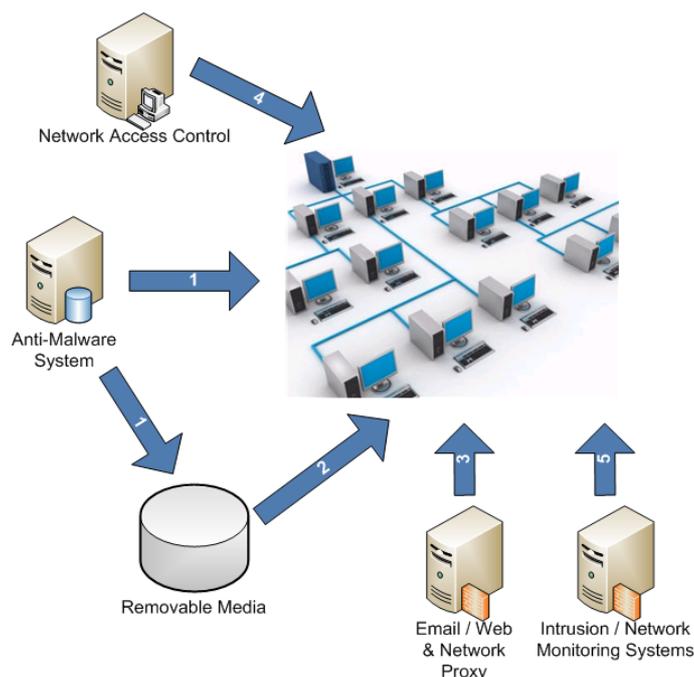

Figure 5

A control system is a device or set of devices to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining anti-malware systems and threat vectors such as removable media. The following list of the steps in figure 5 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Anti-malware systems analyze production systems and removable media.
- Step 2: Removable media is analyzed when connected to production systems.
- Step 3: Email/web and network proxy devices analyze all incoming and outgoing traffic.
- Step 4: Network access control monitors all systems connected to the network.
- Step 5: Intrusion/network monitoring systems perform continuous monitoring looking for signs of malware.

4.6 CSC 6: Application Software Security

Manage the security lifecycle of all in-house developed and acquired software in order to prevent, detect, and correct security weaknesses.

Why Is This Control Critical?

Attacks often take advantage of vulnerabilities found in web-based and other application software. Vulnerabilities can be present for many reasons, including coding mistakes, logic errors, incomplete requirements, and failure to test for unusual or unexpected conditions. Examples of specific errors include: the failure to check the size of user input; failure to filter out unneeded but potentially malicious character sequences from input streams; failure to initialize and clear variables; and poor memory management allowing flaws in one part of the software to affect unrelated (and more security critical) portions. There is a flood of public and private information about such vulnerabilities available to attackers and defenders alike, as well as a robust marketplace for tools and techniques to allow "weaponization" of vulnerabilities into exploits. Attackers can inject specific exploits, including buffer overflows, SQL injection attacks, cross-site scripting, cross-site request forgery, and click-jacking of code to gain control over vulnerable machines. In one attack, more than 1 million web servers were exploited and turned into infection engines for visitors to those sites using SQL injection. During that attack, trusted websites from state governments and other organizations compromised by attackers were used to infect hundreds of thousands of browsers that accessed those websites. Many more web and non-web application vulnerabilities are discovered on a regular basis.

*How to Implement This Control***Table 6**

ID #	Description	Category
CSC 6-1	For all acquired application software, check that the version you are using is still supported by the vendor. If not, update to the most current version and install all relevant patches and vendor security recommendations.	<i>Quick Win</i>
CSC 6-2	Protect web applications by deploying web application firewalls (WAFs) that inspect all traffic flowing to the web application for common web application attacks, including but not limited to cross-site scripting, SQL injection, command injection, and directory traversal attacks. For applications that are not web-based, specific application firewalls should be deployed if such tools are available for the given application type. If the traffic is encrypted, the device should either sit behind the encryption or be capable of decrypting the traffic prior to analysis. If neither option is appropriate, a host-based web application firewall should be deployed.	<i>Quick Win</i>
CSC 6-3	For in-house developed software, ensure that explicit error checking is performed and documented for all input, including for size, data type, and acceptable ranges or formats.	<i>Visibility/ Attribution</i>
CSC 6-4	Test in-house-developed and third-party-procured web applications for common security weaknesses using automated remote web application scanners prior to deployment, whenever updates are made to the application, and on a regular recurring basis. Include tests for application behaviour under denial-of-service or resource exhaustion attacks.	<i>Visibility/ Attribution</i>
CSC 6-5	Do not display system error messages to end-users (output sanitization).	<i>Visibility/ Attribution</i>
CSC 6-6	Maintain separate environments for production and nonproduction systems. Developers should not typically have unmonitored access to production environments.	<i>Visibility/ Attribution</i>
CSC 6-7	Test in-house-developed web and other application software for coding errors and potential vulnerabilities prior to deployment using automated static code analysis software, as well as manual testing and inspection. In particular, input validation and output encoding routines of application software should be reviewed and tested.	<i>Configuration/ Hygiene</i>
CSC 6-8	For acquired application software, examine the product security process of the vendor (history of vulnerabilities, customer notification, patching/remediation) as part of the overall enterprise risk management process.	<i>Configuration/ Hygiene</i>
CSC 6-9	For applications that rely on a database, use standard hardening configuration templates. All systems that are part of critical business processes should also be tested.	<i>Configuration/ Hygiene</i>
CSC 6-10	Ensure that all software development personnel receive training in writing secure code for their specific development environment.	<i>Configuration/ Hygiene</i>
CSC 6-11	For in-house developed applications, ensure that development artifacts (sample data and scripts; unused libraries, components, debug code; or tools) are not included in the deployed software, or accessible in the production environment.	<i>Configuration/ Hygiene</i>

CSC 6 Procedures and Tools

The security of applications (in-house developed or acquired) is a complex activity requiring a complete program encompassing enterprise-wide policy, technology, and the role of people. These are often broadly defined or required by formal Risk Management Frameworks and processes.

A comprehensive treatment of this topic is beyond the scope of the Critical Security Controls. However, the actions in CSC 6 provide specific, high-priority steps that can improve Application Software Security. In addition, we recommend use of the many excellent comprehensive resources dedicated to this topic. Examples include: the DHS "Build Security In" Program buildsecurityin.us-cert.gov, and The Open Web Application Security Project (OWASP) www.owasp.org.

CSC 6 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Can the application system detect attacks & block them within 24 hours of being detected (yes or no)?
- 2) Are all Internet facing applications scanned by web application vulnerability scanners at least weekly (yes or no)?
- 3) How long does it take for alerts to be generated & sent to system administrators that a vulnerability scan has or has not completed (time in minutes)?
- 4) Are all vulnerabilities detected by the scanning tools fixed or remediated within 15 days of detection (yes or no)?

CSC 6 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What percentage of the organization's custom applications have not been recently scanned by an application security code scanner (by business unit)?
- 2) What percentage of the organization's database systems have not been recently scanned by a database specific vulnerability scanner (by business unit)?
- 3) What is the aggregate vulnerability rating for all application and database system in the organization (by business unit)?

CSC 6 Effectiveness Test

To evaluate the implementation of Control 6 on a monthly basis, an evaluation team has to use a web application vulnerability scanner to test for each relevant type of flaw identified in the regularly updated list of the "25 Most Dangerous Programming Errors" by MITRE and the SANS Institute. The scanner has to be configured to assess all of the organization's Internet-accessible web applications to identify such errors. The evaluation team has to verify that the scan is detected within 24 hours and that an alert is generated.

In addition to the web application vulnerability scanner, the evaluation team has to also run static code analysis tools and database configuration review tools against Internet-accessible applications to identify security flaws on a monthly basis.

The evaluation team has to verify that all high-risk vulnerabilities identified by the automated vulnerability scanning tools or static code analysis tools have been remediated or addressed through a compensating control (such as a web application firewall) within 15 days of discovery.

The evaluation team has to verify that application vulnerability scanning tools have successfully completed their regular scans for the previous 30 cycles of scanning by reviewing archived alerts and reports to ensure that the scan was completed. If a scan was not completed successfully, the system has to alert or send e-mail to enterprise administrative personnel indicating what happened. If a scan could not be completed in that timeframe, the evaluation team has to verify that an alert or e-mail was generated indicating that the scan did not finish.

CSC 6 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

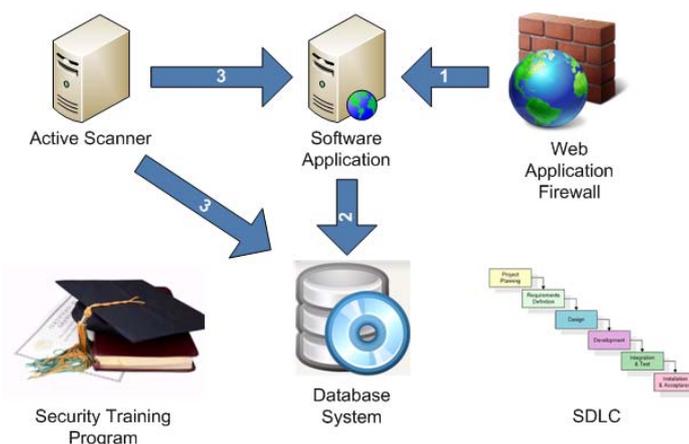

Figure 6

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the process of monitoring applications and using tools that enforce a security style when developing applications.

The following list of the steps in figure 6 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Web application firewalls protect connections to internal web applications.
- Step 2: Software applications securely connect to database systems.
- Step 3: Code analysis and vulnerability scanning tools scan application systems and database systems.

4.7 CSC 7: Wireless Access Control

The processes and tools used to track/control/prevent/correct the security use of wireless local area networks (LANs), access points, and wireless client systems.

Why Is This Control Critical?

Major thefts of data have been initiated by attackers who have gained wireless access to organizations from outside the physical building, bypassing organizations' security perimeters by connecting wirelessly to access points inside the organization. Wireless clients accompanying traveling officials are infected on a regular basis through remote exploitation during air travel or in cyber cafes. Such exploited systems are then used as back doors when they are reconnected to the network of a target organization. Still other organizations have reported the discovery of unauthorized wireless access points on their networks, planted and sometimes hidden for unrestricted access to an internal network. Because they do not require direct physical connections, wireless devices are a convenient vector for attackers to maintain long-term access into a target environment.

*How to Implement This Control***Table 7**

ID #	Description	Category
CSC 7-1	Ensure that each wireless device connected to the network matches an authorized configuration and security profile, with a documented owner of the connection and a defined business need. Organizations should deny access to those wireless devices that do not have such a configuration and profile.	<i>Quick win</i>
CSC 7-2	Configure network vulnerability scanning tools to detect wireless access points connected to the wired network. Identified devices should be reconciled against a list of authorized wireless access points. Unauthorized (i.e. rogue) access points should be deactivated.	<i>Quick win</i>
CSC 7-3	Use wireless intrusion detection systems (WIDS) to identify rogue wireless devices and detect attack attempts and successful compromises. In addition to WIDS, all wireless traffic should be monitored by WIDS as traffic passes into the wired network.	<i>Visibility/ Attribution</i>
CSC 7-4	Where a specific business need for wireless access has been identified, configure wireless access on client machines to allow access only to authorized wireless networks.	<i>Configuration/ Hygiene</i>
CSC 7-5	For devices that do not have an essential wireless business purpose, disable wireless access in the hardware configuration (basic input/output system or extensible firmware interface), with password protections to lower the possibility that the user will override such configurations.	<i>Configuration/ Hygiene</i>
CSC 7-6	Ensure that all wireless traffic leverages at least Advanced Encryption Standard (AES) encryption used with at least Wi-Fi Protected Access 2 (WPA2) protection.	<i>Configuration/ Hygiene</i>
CSC 7-7	Ensure that wireless networks use authentication protocols such as Extensible Authentication Protocol-Transport Layer Security (EAP/TLS), which provide credential protection and mutual authentication.	<i>Configuration/ Hygiene</i>
CSC 7-8	Disable peer-to-peer wireless network capabilities on wireless clients, unless such functionality meets a documented business need.	<i>Configuration/ Hygiene</i>
CSC 7-9	Disable wireless peripheral access of devices (such as Bluetooth), unless such access is required for a documented business need.	<i>Configuration/ Hygiene</i>
CSC 7-10	Create separate virtual local area networks (VLANs) for BYOD systems or other untrusted devices. Internet access from this VLAN should go through at least the same border as corporate traffic. Enterprise access from this VLAN should be treated as untrusted and filtered and audited accordingly.	<i>Configuration/Hygiene</i>

CSC 7 Procedures and Tools

Effective organizations run commercial wireless scanning, detection, and discovery tools as well as commercial wireless intrusion detection systems.

Additionally, the security team should periodically capture wireless traffic from within the borders of a facility and use free and commercial analysis tools to determine whether the wireless traffic was transmitted using weaker protocols or encryption than the organization mandates. When devices relying on weak wireless security settings are identified, they should be found within the organization's asset inventory and either reconfigured more securely or denied access to the organization network.

Additionally, the security team should employ remote management tools on the wired network to pull information about the wireless capabilities and devices connected to managed systems.

CSC 7 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Are systems capable of identifying unauthorized wireless devices or configurations when they are within range of the organization's systems or connected to their networks (yes or no)?
- 2) How long does it take to generate alerts about unauthorized wireless devices that are detected (time in minutes)?
- 3) How long does it take for unauthorized wireless devices to be blocked from connecting or isolated from the network (time in minutes)?

- 4) Are additional alerts generated every 24 hours after the initial alert until the system is isolated or removed from the network (yes or no)?
- 5) Is the system able to identify the location, department, and other details of where authorized and unauthorized wireless devices are plugged into the network (yes or no)?

CSC 7 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) How many rogue wireless access points have been discovered recently in the organization (by business unit)? This should include non-persistent, temporary and transient access points.
- 2) What is the average time that it takes to remove rogue access points from the organization's network (by business unit)?
- 3) How many wireless access points or clients have been discovered using an unauthorized wireless configuration recently in the organization (by business unit)?

CSC 7 Effectiveness Test

To evaluate the implementation of Control 7 on a periodic basis, the evaluation team has to configure 10 unauthorized but hardened wireless clients and wireless access points to the organization's network and attempt to connect them to its wireless networks. In the case of wireless access points, these access points have to not be directly connected to the organization's trusted network. Instead, they have to simply be configured to act as a wireless gateway without physically connecting to a wired network interface. In the case of scanning for wireless access points from a wired interface, the connected access point has to have the wireless radio disabled for the duration of the test. These systems have to be configured to test each of the following scenarios:

- A wireless client with an unauthorized service set identifier configured on it.
- A wireless client with improper encryption configured.
- A wireless client with improper authentication configured.
- A wireless access point with improper encryption configured.
- A wireless access point with improper authentication configured.
- A completely rogue wireless access point using an unauthorized configuration.

When any of the above-noted systems attempt to connect to the wireless network, an alert has to be generated and enterprise staff has to respond to the alerts to isolate the detected device or remove the device from the network.

CSC 7 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

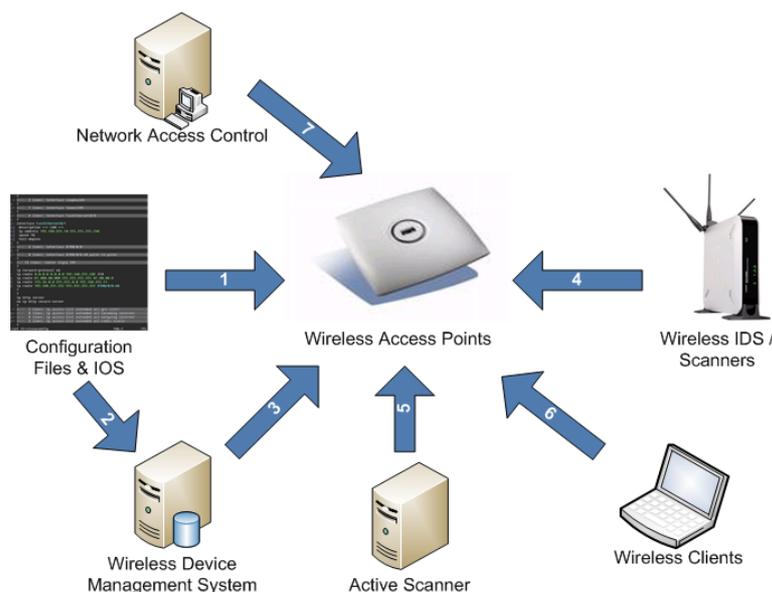

Figure 7

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the configuration and management of wireless devices, wireless IDS/scanners, wireless device management systems, and vulnerability scanners. The following list of the steps in figure 7 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Hardened configurations applied to wireless devices.
- Step 2: Hardened configurations managed by a configuration management system.
- Step 3: Configuration management system manages the configurations on wireless devices.
- Step 4: Wireless IDS monitor usage of wireless communications.
- Step 5: Vulnerability scanners scan wireless devices for potential vulnerabilities.
- Step 6: Wireless clients utilize wireless infrastructure systems in a secure manner.

4.8 CSC 8: Data Recovery Capability

The processes and tools used to properly back up critical information with a proven methodology for timely recovery of it.

Why Is This Control Critical?

When attackers compromise machines, they often make significant changes to configurations and software. Sometimes attackers also make subtle alterations of data stored on compromised machines, potentially jeopardizing organizational effectiveness with polluted information. When the attackers are discovered, it can be extremely difficult for organizations without a trustworthy data recovery capability to remove all aspects of the attacker's presence on the machine.

*How to Implement This Control***Table 8**

ID #	Description	Category
CSC 8-1	Ensure that each system is automatically backed up on at least a weekly basis, and more often for systems storing sensitive information. To help ensure the ability to rapidly restore a system from backup, the operating system, application software, and data on a machine should each be included in the overall backup procedure. These three components of a system do not have to be included in the same backup file or use the same backup software. There should be multiple backups over time, so that in the event of malware infection, restoration can be from a version that is believed to predate the original infection. All backup policies should be compliant with any regulatory or official requirements.	<i>Quick win</i>
CSC 8-2	Test data on backup media on a regular basis by performing a data restoration process to ensure that the backup is properly working.	<i>Quick win</i>
CSC 8-3	Ensure that backups are properly protected via physical security or encryption when they are stored, as well as when they are moved across the network. This includes remote backups and cloud services.	<i>Configuration/ Hygiene</i>
CSC 8-4	Ensure that key systems have at least one backup destination that is not continuously addressable through operating system calls. This will mitigate the risk of attacks like CryptoLocker which seek to encrypt or damage data on all addressable data shares, including backup destinations.	

CSC 8 Procedures and Tools

Once per quarter (or whenever new backup equipment is purchased), a testing team should evaluate a random sample of system backups by attempting to restore them on a test bed environment. The restored systems should be verified to ensure that the operating system, application, and data from the backup are all intact and functional.

In the event of malware infection, restoration procedures should use a version of the backup which is believed to predate the original infection.

CSC 8 Effectiveness Metrics

Percentage of systems with current backups within their target frequency (targets can vary by system role, type, and criticality).

CSC 8 Automation Metrics

None.

CSC 8 Effectiveness Test

The evaluation team should identify 5 systems in the environment and restore to a test system (physical or virtual) using the most recent backup. Verify that the system has been restored properly by comparing the restore results to the original system.

CSC 8 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

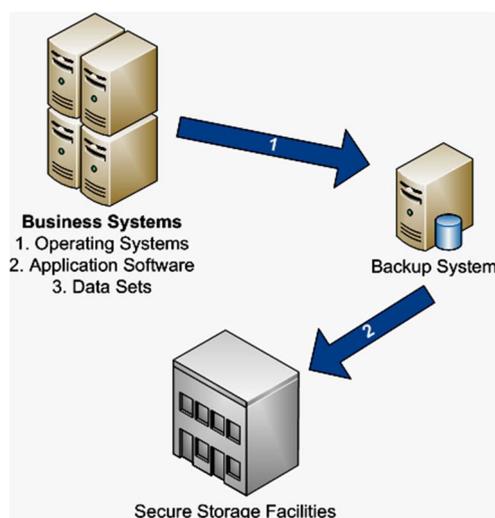

Figure 8

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining an organization's capability to restore systems in the event that data need to be restored because of a data loss or breach of a system. While backups are certainly an important part of this process, the ability to restore data is the critical component. The following list of the steps in figure 8 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Production business systems backed up on a regular basis to authorized organizational backup systems.
- Step 2: Backups created are stored offline at secure storage facilities.

4.9 CSC 9: Security Skills Assessment and Appropriate Training to Fill Gaps

For all functional roles in the organization (prioritizing those mission-critical to the business and its security), identify the specific knowledge, skills, and abilities needed to support defence of the enterprise; develop and execute an integrated plan to assess, identify gaps, and remediate through policy, organizational planning, training, and awareness programs.

Why Is This Control Critical?

It is tempting to think of cyber defence primarily as a technical challenge, but the actions of people also play a critical part in the success or failure of an enterprise. People fulfil important functions at every stage of system design, implementation, operation, use, and oversight. Examples include: the actions of end users (who can fall prey to social engineering schemes such as phishing); IT operations (who may not recognize the security implications of IT artifacts and logs); security analysts (who struggle to keep up with an explosion of new information); system developers and programmers (who do not understand the opportunity to resolve root cause vulnerabilities early in the system life-cycle); and executives and system owners (who struggle to quantify the role that cybersecurity plays in overall operational/mission risk, and have no reasonable way to make relevant investment decisions).

Attackers are very conscious of these issues and use them to plan their exploitations by, for example: carefully crafting phishing messages that look like routine and expected traffic to an unwary user; exploiting the gaps or seams between policy and technology (e.g. policies that have no technical enforcement); working within the time window of patching or log review; using nominally non-security-critical systems as jump points or bots.

No cyber defence approach can begin to address cyber risk without a means to address this fundamental vulnerability. Conversely, empowering people with good cyber defence habits can significantly increase readiness.

*How to Implement This Control***Table 9**

ID #	Description	Category
CSC 9-1	Perform gap analysis to see which skills employees need and which behaviours employees are not adhering to, using this information to build a baseline training and awareness roadmap for all employees.	<i>Quick win</i>
CSC 9-2	Deliver training to fill the skills gap. If possible, use more senior staff to deliver the training. A second option is to have outside teachers provide training onsite so the examples used will be directly relevant. If you have small numbers of people to train, use training conferences or online training to fill the gaps.	<i>Quick win</i>
CSC 9-3	Implement an online security awareness program that: <ul style="list-style-type: none"> (1) focuses only on the methods commonly used in intrusions that can be blocked through individual action; (2) is delivered in short online modules convenient for employees; (3) is updated frequently (at least annually) to represent the latest attack techniques; (4) is mandated for completion by all employees at least annually; and (5) is reliably monitored for employee completion. 	<i>Quick win</i>
CSC 9-4	Validate and improve awareness levels through periodic tests to see whether employees will click on a link from suspicious e-mail or provide sensitive information on the telephone without following appropriate procedures for authenticating a caller; targeted training should be provided to those who fall victim to the exercise.	<i>Visibility/ Hygiene</i>
CSC 9-5	Use security skills assessments for each of the mission-critical roles to identify skills gaps. Use hands-on, real-world examples to measure mastery. If you do not have such assessments, use one of the available online competitions that simulate real-world scenarios for each of the identified jobs in order to measure skills mastery.	<i>Configuration/ Hygiene</i>

CSC 9 Procedures and Tools

An effective enterprise-wide training program should take a holistic approach and consider policy and technology at the same time as the training of people. For example, policies should be designed with technical measurement and enforcement when possible, reinforced by training to fill gaps; technical controls can be implemented to bound and minimize the opportunity for people to make mistakes, and so focus the training on things that cannot be managed technically.

To be effective in both cost and outcome, security training should be prioritized, focused, and specific (for example, using a S.M.A.R.T. metrics program). A key way to prioritize training is to focus first on those jobs and roles that are *critical* to the mission or business outcome of the enterprise. One way to identify these mission-critical jobs is to reference the list prepared by the Council on CyberSecurity (which builds upon the work of the 2012 Task Force on Cyber Skills established by the Secretary of Homeland Security):

- 1) System and Network Penetration Testers;
- 2) Application Penetration Testers;
- 3) Security Monitoring and Event Analysts;
- 4) Incident Responders In-Depth;
- 5) Counter-Intelligence/Insider Threat Analysts;
- 6) Risk Assessment Engineers;
- 7) Secure Coders and Code Reviewers;
- 8) Security Engineers/Architecture and Design;
- 9) Security Engineers/Operations; and
- 10) Advanced Forensics Analysts.

The Council has validated this list as consistent with the broader NIST National Initiative on Cybersecurity Education (NICE) framework, and with the needs of many enterprises in government and industry. Training for these mission critical roles should be supplemented with foundational security training for all users (<http://www.counciloncybersecurity.org/workforce/>).

General awareness training for all users also plays an important role. But even this training should be tailored to functional roles and focused on specific actions that put the organization at risk, and measured in order to drive remediation.

The key to upgrading skills is measurement through assessments that show both the employee and the employer where knowledge is sufficient and where there are gaps. Once the gaps have been identified, those employees who have the requisite skills and knowledge can be called upon to mentor employees who need to improve their skills. In addition, the organization can develop training plans to fill the gaps and maintain employee readiness.

A full treatment of this topic is beyond the scope of the Critical Security Controls. However, the actions in CSC 9 provide specific, high-priority steps that can improve enterprise security, and should be a part of any comprehensive security training program.

CSC 9 Effectiveness Metrics

- 1) Participation rate for online training courses - percentage of staff completing security training (by business unit).
- 2) Average scores of online tests, compared to baseline (previous tests, industry data if available, etc.) by business unit.
- 3) Average scores of periodic tests (e.g. click rates for test phishing emails) by business unit.
- 4) Individual scores on skill assessment tests for individual mission critical roles by business unit.
- 5) Retention (or job opening fill rate) of mission critical roles (org/unit metric).

CSC 9 Automation Metrics

None.

CSC 9 Effectiveness Test

None.

CSC 9 System Entity Relationship Diagram

None.

4.10 CSC 10: Secure Configurations for Network Devices such as Firewalls, Routers, and Switches

Establish, implement, and actively manage (track, report on, correct) the security configuration of network infrastructure devices using a rigorous configuration management and change control process in order to prevent attackers from exploiting vulnerable services and settings.

Why Is This Control Critical?

As delivered from manufacturers and resellers, the default configurations for network infrastructure devices are geared for ease-of-deployment and ease-of-use - not security. Open services and ports, default accounts (including service accounts) or passwords, support for older (vulnerable) protocols, pre-installation of unneeded software; all can be exploitable in their default state.

Attackers take advantage of network devices becoming less securely configured over time as users demand exceptions for specific business needs. Sometimes the exceptions are deployed and then left undone when they are no longer applicable to the business needs. In some cases, the security risk of the exception is neither properly analyzed nor measured against the associated business need and can change over time. Attackers search for vulnerable default settings, electronic holes in firewalls, routers, and switches and use those to penetrate defences. They exploit flaws in these devices to gain access to networks, redirect traffic on a network, and intercept information while in transmission. Through such actions, the attacker gains access to sensitive data, alters important information, or even uses a compromised machine to pose as another trusted system on the network.

How to Implement This Control

Table 10

ID #	Description	Category
CSC 10-1	Compare firewall, router, and switch configuration against standard secure configurations defined for each type of network device in use in the organization. The security configuration of such devices should be documented, reviewed, and approved by an organization change control board. Any deviations from the standard configuration or updates to the standard configuration should be documented and approved in a change control system.	<i>Quick win</i>
CSC 10-2	All new configuration rules beyond a baseline-hardened configuration that allow traffic to flow through network security devices, such as firewalls and network-based IPS, should be documented and recorded in a configuration management system, with a specific business reason for each change, a specific individual's name responsible for that business need, and an expected duration of the need.	<i>Configuration/ Hygiene</i>
CSC 10-3	Use automated tools to verify standard device configurations and detect changes. All alterations to such files should be automatically reported to security personnel.	<i>Configuration/ Hygiene</i>
CSC 10-4	Manage network devices using two-factor authentication and encrypted sessions.	<i>Configuration/ Hygiene</i>
CSC 10-5	Install the latest stable version of any security-related updates.	<i>Configuration/ Hygiene</i>
CSC 10-6	Manage the network infrastructure across network connections that are separated from the business use of that network, relying on separate VLANs or, preferably, on entirely different physical connectivity for management sessions for network devices.	Advanced

CSC 10 Procedures and Tools

Some organizations use commercial tools that evaluate the rule set of network filtering devices to determine whether they are consistent or in conflict, providing an automated sanity check of network filters and search for errors in rule sets or access controls lists (ACLs) that may allow unintended services through the device. Such tools should be run each time significant changes are made to firewall rule sets, router ACLs, or other filtering technologies.

CSC 10 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take to detect configuration changes to a network system (time in minutes)?
- 2) How long does it take the scanners to alert the organization's administrators that an unauthorized configuration change has occurred (time in minutes)?
- 3) How long does it take to block/quarantine unauthorized changes on network systems (time in minutes)?
- 4) Are the scanners able to identify the location, department, and other critical details about the systems where unauthorized changes occurred (yes or no)?

CSC 10 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What is the percentage of network devices that are not currently configured with a security configuration that matches the organization's approved configuration standard (by business unit)?
- 2) What is the percentage of network devices whose security configuration is not enforced by the organization's technical configuration management applications (by business unit)?
- 3) What is the percentage of network devices that are not up to date with the latest available operating system software security patches (by business unit)?
- 4) What is the percentage of network devices do not require two-factor authentication to administer the device (by business unit)?

CSC 10 Effectiveness Test

To evaluate the implementation of Control 10 on a periodic basis, an evaluation team has to make a change to each type of network device plugged into the network. At a minimum, routers, switches, and firewalls need to be tested. If they exist, IPS, IDS, and other network devices have to be included. Backups have to be made prior to making any changes to critical network devices. It is critical that changes not impact or weaken the security of the device. Acceptable changes include but are not limited to making a comment or adding a duplicate entry in the configuration. The change has to be performed twice for each critical device. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the changes to the device within 24 hours. It is important that the evaluation team verify that all unauthorized changes have been detected, the account making the changes has been recorded, and the changes have resulted in an alert or e-mail notification. The evaluation team has to verify that the system provides details of the location of each device, including information about the asset owner. While the 24-hour timeframe represents the current metric to help organizations improve their state of security, in the future organizations should strive for even more rapid alerting and isolation, with notification about unauthorized configuration changes in network devices sent within two minutes.

If appropriate, an additional test has to be performed on a daily basis to ensure that other protocols such as IPv6 are being filtered properly.

CSC 10 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

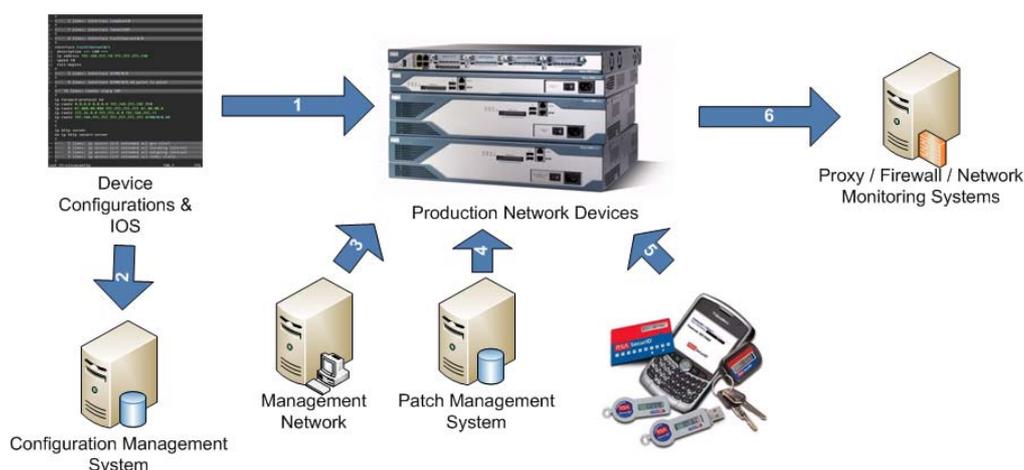

Figure 9

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case we are examining the network devices, test lab network devices, configuration systems, and configuration management devices. The following list of the steps in figure 9 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Hardened device configurations applied to production devices.
- Step 2: Hardened device configuration stored in a secure configuration management system.
- Step 3: Management network system validates configurations on production network devices.
- Step 4: Patch management system applies tested software updates to production network devices.
- Step 5: Two-factor authentication system required for administrative access to production devices.
- Step 6: Proxy/firewall/network monitoring systems analyze all connections to production network devices.

4.11 CSC 11: Limitation and Control of Network Ports, Protocols, and Services

Manage (track/control/correct) the ongoing operational use of ports, protocols, and services on networked devices in order to minimize windows of vulnerability available to attackers.

Why Is This Control Critical?

Attackers search for remotely accessible network services that are vulnerable to exploitation. Common examples include poorly configured web servers, mail servers, file and print services, and domain name system (DNS) servers installed by default on a variety of different device types, often without a business need for the given service. Many software packages automatically install services and turn them on as part of the installation of the main software package without informing a user or administrator that the services have been enabled. Attackers scan for such issues and attempt to exploit these services, often attempting default user IDs and passwords or widely available exploitation code.

How to Implement This Control

Table 11

ID #	Description	Category
CSC 11-1	Ensure that only ports, protocols, and services with validated business needs are running on each system.	Quick win
CSC 11-2	Apply host-based firewalls or port filtering tools on end systems, with a default-deny rule that drops all traffic except those services and ports that are explicitly allowed.	Quick win
CSC 11-3	Perform automated port scans on a regular basis against all key servers and compared to a known effective baseline. If a change that is not listed on the organization's approved baseline is discovered, an alert should be generated and reviewed.	Quick win
CSC 11-4	Keep all services up to date and uninstall and remove any unnecessary components from the system.	Quick win
CSC 11-5	Verify any server that is visible from the Internet or an untrusted network, and if it is not required for business purposes, move it to an internal VLAN and give it a private address.	Visibility/ Attribution
CSC 11-6	Operate critical services on separate physical or logical host machines, such as DNS, file, mail, web, and database servers.	Configuration/ Hygiene
CSC 11-7	Place application firewalls in front of any critical servers to verify and validate the traffic going to the server. Any unauthorized services or traffic should be blocked and an alert generated.	Advanced

CSC 11 Procedures and Tools

Port scanning tools are used to determine which services are listening on the network for a range of target systems. In addition to determining which ports are open, effective port scanners can be configured to identify the version of the protocol and service listening on each discovered open port. This list of services and their versions are compared against an inventory of services required by the organization for each server and workstation in an asset management system. Recently added features in these port scanners are being used to determine the changes in services offered by scanned machines on the network since the previous scan, helping security personnel identify differences over time.

CSC 11 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) How long does it take systems to identify any new unauthorized listening network ports that are installed on network systems (time in minutes)?
- 2) How long does it take for alerts to be generated about new services being installed (time in minutes)?
- 3) Are alerts then sent every 24 hours until the listening network port has been disabled or it has been authorized by change management (yes or no)?
- 4) Do alerts indicate the location, department, and other details about the system where authorized and unauthorized network ports are running (yes or no)?

CSC 11 Automation Metrics

In order to automate the collection of relevant data from these systems, organization should gather the following information with automated technical sensors:

- 1) What is the percentage of the organization's systems that are not currently running a host based firewall (by business unit)?
- 2) How many unauthorized services are currently running on the organization's business systems (by business unit)?
- 3) How many deviations from approved service baselines have been discovered recently on the organization's business systems (by business unit)?

CSC 11 Effectiveness Test

To evaluate the implementation of Control 11 on a periodic basis, the evaluation team has to install hardened test services with network listeners on 10 locations on the network, including a selection of subnets associated with DMZs, workstations, and servers. The selection of these systems has to be as random as possible and include a cross-section of the organization's systems and locations. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the newly installed services within 24 hours of the services being installed on the network. The team has to verify that the system provides details of the location of all of the systems where test services have been installed.

CSC 11 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

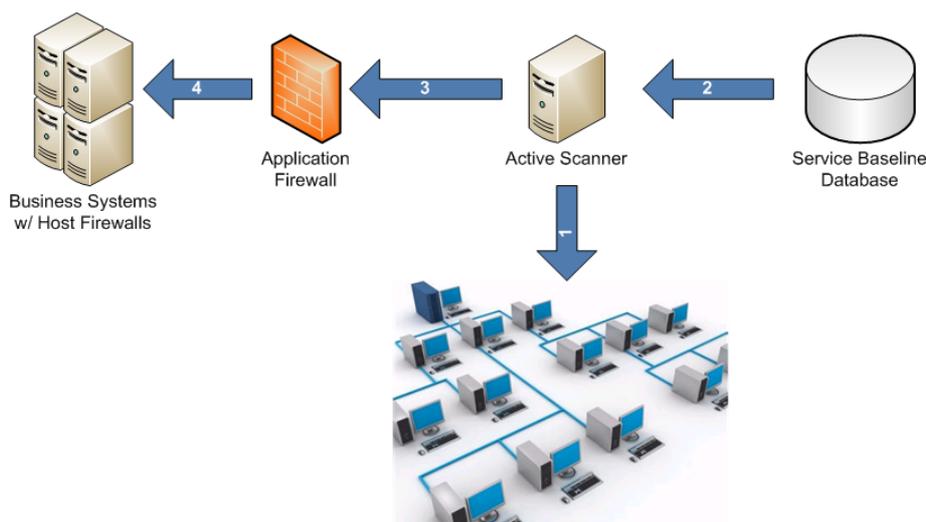

Figure 10

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining how active scanning systems gather information on network devices and evaluate that data against the authorized service baseline database. The following list of the steps in figure 10 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Active scanner analyzes production systems for unauthorized ports, protocols, and services.
- Step 2: System baselines regularly updated based on necessary/required services.
- Step 3: Active scanner validates which ports, protocols, and services are blocked or allowed by the application firewall.
- Step 4: Active scanner validates which ports, protocols, and services are accessible on business systems protected with host-based firewalls.

4.12 CSC 12: Controlled Use of Administrative Privileges

The processes and tools used to track/control/prevent/correct the use, assignment, and configuration of administrative privileges on computers, networks, and applications.

Why Is This Control Critical?

The misuse of administrative privileges is a primary method for attackers to spread inside a target enterprise. Two very common attacker techniques take advantage of uncontrolled administrative privileges. In the first, a workstation user running as a privileged user, is fooled into opening a malicious e-mail attachment, downloading and opening a file from a malicious website, or simply surfing to a website hosting attacker content that can automatically exploit browsers. The file or exploit contains executable code that runs on the victim's machine either automatically or by tricking the user into executing the attacker's content. If the victim user's account has administrative privileges, the attacker can take over the victim's machine completely and install keystroke loggers, sniffers, and remote control software to find administrative passwords and other sensitive data. Similar attacks occur with e-mail. An administrator inadvertently opens an e-mail that contains an infected attachment and this is used to obtain a pivot point within the network that is used to attack other systems.

The second common technique used by attackers is elevation of privileges by guessing or cracking a password for an administrative user to gain access to a target machine. If administrative privileges are loosely and widely distributed, or identical to passwords used on less critical systems, the attacker has a much easier time gaining full control of systems, because there are many more accounts that can act as avenues for the attacker to compromise administrative privileges.

*How to Implement This Control***Table 12**

ID #	Description	Category
CSC 12-1	Minimize administrative privileges and only use administrative accounts when they are required. Implement focused auditing on the use of administrative privileged functions and monitor for anomalous behaviour.	<i>Quick win (One of the "First Five")</i>
CSC 12-2	Use automated tools to inventory all administrative accounts and validate that each person with administrative privileges on desktops, laptops, and servers is authorized by a senior executive.	<i>Quick win</i>
CSC 12-3	Configure all administrative passwords to be complex and contain letters, numbers, and special characters intermixed, and with no dictionary words present in the password. Pass phrases containing multiple dictionary words, along with special characters, are acceptable if they are of a reasonable length.	<i>Quick win</i>
CSC 12-4	Before deploying any new devices in a networked environment, change all default passwords for applications, operating systems, routers, firewalls, wireless access points, and other systems to have values consistent with administration-level accounts.	<i>Quick win</i>
CSC 12-5	Ensure that all service accounts have long and difficult-to-guess passwords that are changed on a periodic basis, as is done for traditional user and administrative passwords.	<i>Quick win</i>
CSC 12-6	Passwords should be hashed or encrypted in storage. Passwords that are hashed should be salted and follow guidance provided in NIST SP 800-132 [i.3] or similar guidance. Files containing these encrypted or hashed passwords required for systems to authenticate users should be readable only with super-user privileges.	<i>Quick win</i>
CSC 12-7	Utilize access control lists to ensure that administrative accounts are used only for system administration activities, and not for reading e-mail, composing documents, or surfing the Internet. Web browsers and e-mail clients especially have to be configured to never run as administrator.	<i>Quick win</i>
CSC 12-8	Through policy and user awareness, require that administrators establish unique, different passwords for their administrative and non-administrative accounts. Each person requiring administrative access should be given his/her own separate account. Users should only use the Windows® "administrator" or Unix® "root" accounts in emergency situations. Domain administration accounts should be used when required for system administration instead of local administrative accounts.	<i>Quick win</i>
CSC 12-9	Configure operating systems so that passwords cannot be re-used within a timeframe of six months.	<i>Quick win</i>
CSC 12-10	Configure systems to issue a log entry and alert when an account is added to or removed from a domain administrators' group, or when a new local administrator account is added on a system.	<i>Visibility/ Attribution</i>
CSC 12-11	Configure systems to issue a log entry and alert when unsuccessful login to an administrative account is attempted.	<i>Visibility/ Attribution</i>
CSC 12-12	Use multifactor authentication for all administrative access, including domain administrative access. Multi-factor authentication can include a variety of techniques, to include the use of smart cards with certificates, One Time Password (OTP) tokens, and biometrics.	<i>Configuration/ Hygiene</i>
CSC 12-13	When using certificates to enable multi-factor certificate-based authentication, ensure that the private keys are protected using strong passwords or are stored in trusted, secure hardware tokens.	<i>Configuration/ Hygiene</i>
CSC 12-14	Block access to a machine (either remotely or locally) for administrator-level accounts. Instead, administrators should be required to access a system using a fully logged and non-administrative account. Then, once logged on to the machine without administrative privileges, the administrator should transition to administrative privileges using tools such as Sudo on Linux/Unix®, RunAs on Windows®, and other similar facilities for other types of systems. Users would use their own administrative accounts and enter a password each time that is different than their user account.	<i>Configuration/ Hygiene</i>

CSC 12 Procedures and Tools

Built-in operating system features can extract lists of accounts with super-user privileges, both locally on individual systems and on overall domain controllers. To verify that users with high-privileged accounts do not use such accounts for day-to-day web surfing and e-mail reading, security personnel should periodically gather a list of running processes to determine whether any browsers or e-mail readers are running with high privileges. Such information gathering can be scripted, with short shell scripts searching for a dozen or more different browsers, e-mail readers, and document editing programs running with high privileges on machines. Some legitimate system administration activity may require the execution of such programs over the short term, but long-term or frequent use of such programs with administrative privileges could indicate that an administrator is not adhering to this control.

To enforce the requirement for strong passwords, built-in operating system features for minimum password length can be configured to prevent users from choosing short passwords. To enforce password complexity (requiring passwords to be a string of pseudo-random characters), built-in operating system settings or third-party password complexity enforcement tools can be applied.

CSC 12 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Does the system report on log-in to administrative accounts?
- 2) Does the system report on the elevation to administrative access, to include traceability to the user account that performed the elevation?
- 3) Does the system provide an inventory of all administrative accounts?
- 4) Does the system report on the addition of new administrative accounts?
- 5) Does the system allow limitations to be placed on the use of administrative accounts, to include not allowing web browsers and email clients to run as administrator?
- 6) Does the system prevent administrative accounts from logging into machines, either locally or remotely, instead requiring elevation of privileges once logged in with a user account?
- 7) Does the system require strong passwords for all administrative accounts and does the system require update of administrator passwords on a regular basis?
- 8) Does the system audit all attempts to gain access to password files within the system?
- 9) Does the system comply with password policies detailed in the control (yes or no)?
- 10) How long does it take for administrators to be notified about user accounts being added to super user groups (time in minutes)?
- 11) Are additional alerts generated every 24 hours until the user account has been removed from or authorized to be a part of the super user group (yes or no)?

CSC 12 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) How many unauthorized elevated operating system accounts (local administrator/root) are currently configured on the organization's systems (by business unit)?
- 2) How many unauthorized elevated application accounts are currently configured on the organization's systems (by business unit)?
- 3) What percentage of the organization's elevated accounts do not currently adhere to the organization's password standard (by business unit)?
- 4) What percentage of the organization's elevated accounts do not require two-factor authentication (by business unit)?

- 5) How many attempts to upgrade an account to administrative privileges have been detected on the organization's systems recently (by business unit)?
- 6) How many attempts to gain access to password files within the system have been detected on the organization's systems recently (by business unit)?

CSC 12 Effectiveness Test

To evaluate the implementation of Control 12 on a periodic basis, the evaluation team has to attempt a variety of techniques to gain access and exploit administrative accounts within the system. Each of the following tests has to be performed at least three times:

- Attempt to gain access to a cross section of devices within the system, using default administrative passwords.
- Attempt to log-in remotely to machines using administrative accounts directly. Verify that this is disallowed by policy.
- Attempt to log-in directly to a workstation or server with root or administrator accounts. Verify that this is disallowed by policy.
- Attempt to gain access to password files within the system using unauthorized accounts. Verify that access is disallowed and that attempts are logged and reported.
- Attempt to elevate to a privileged account on the system. Verify that the administrator password is required to perform the elevation and that the elevation is logged and reported by the system. Verify that traceability within the audit logs is provided to detail the user account that performed the elevation.
- Attempt to configure weak administrator passwords that are non-compliant with established policy. Verify that the system does not allow weak passwords to be used.
- Attempt to re-use an administrator password that was previously used for the account. Verify that the system requires unique new passwords during each update.

Each of these tests has to be performed from multiple, widely distributed systems on the organization's network in order to test the effectiveness of administrator controls.

CSC 12 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

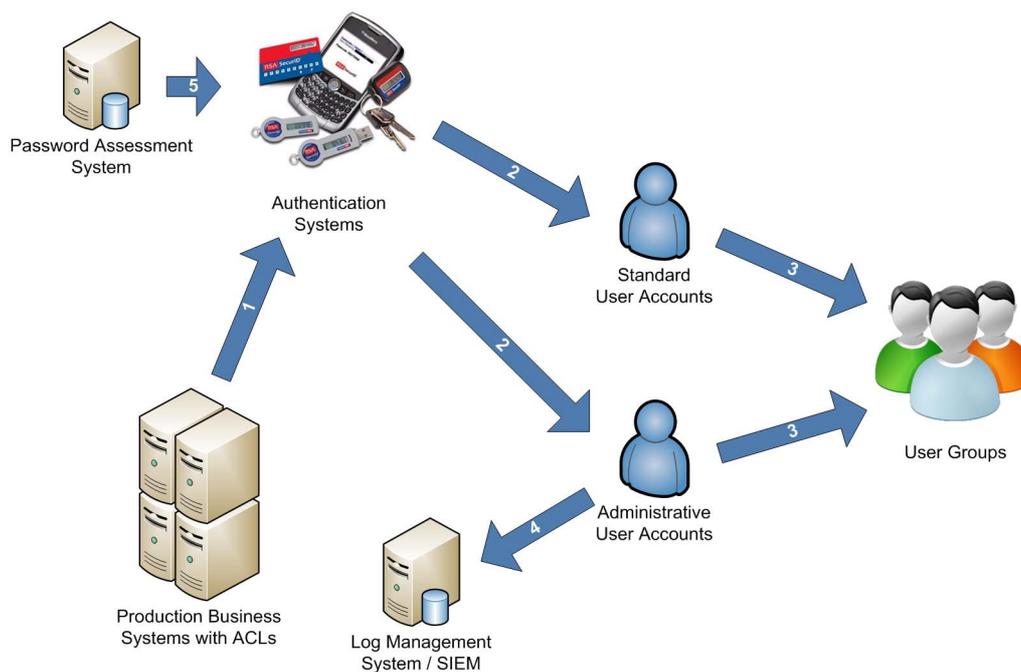

Figure 11

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the components of user account provisioning and user authentication. The following list of the steps in figure 11 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Production systems use proper authentication systems.
- Step 2: Standard and administrative user accounts use proper authentication systems.
- Step 3: Standard and administrative user accounts properly managed via group memberships.
- Step 4: Administrative access to systems properly logged via log management systems.
- Step 5: Password assessment system validates the strength of the authentication systems.

4.13 CSC 13: Boundary Defence

Detect/prevent/correct the flow of information transferring networks of different trust levels with a focus on security-damaging data.

Why Is This Control Critical?

Attackers focus on exploiting systems that they can reach across the Internet, including not only DMZ systems but also workstation and laptop computers that pull content from the Internet through network boundaries. Threats such as organized crime groups and nation-states use configuration and architectural weaknesses found on perimeter systems, network devices, and Internet-accessing client machines to gain initial access into an organization. Then, with a base of operations on these machines, attackers often pivot to get deeper inside the boundary to steal or change information or to set up a persistent presence for later attacks against internal hosts. Additionally, many attacks occur between business partner networks, sometimes referred to as extranets, as attackers hop from one organization's network to another, exploiting vulnerable systems on extranet perimeters.

To control the flow of traffic through network borders and police content by looking for attacks and evidence of compromised machines, boundary defences should be multi-layered, relying on firewalls, proxies, DMZ perimeter networks, and network-based IPS and IDS. It is also critical to filter both inbound and outbound traffic.

It should be noted that boundary lines between internal and external networks are diminishing as a result of increased interconnectivity within and between organizations as well as the rapid rise in deployment of wireless technologies. These blurring lines sometimes allow attackers to gain access inside networks while bypassing boundary systems. However, even with this blurring of boundaries, effective security deployments still rely on carefully configured boundary defences that separate networks with different threat levels, sets of users, and levels of control. And despite the blurring of internal and external networks, effective multi-layered defences of perimeter networks help lower the number of successful attacks, allowing security personnel to focus on attackers who have devised methods to bypass boundary restrictions.

How to Implement This Control

Table 13

ID #	Description	Category
CSC 13-1	Deny communications with (or limit data flow to) known malicious IP addresses (black lists), or limit access only to trusted sites (whitelists). Tests can be periodically carried out by sending packets from bogon source IP addresses (non-routable or otherwise unused IP addresses) into the network to verify that they are not transmitted through network perimeters. Lists of bogon addresses are publicly available on the Internet from various sources, and indicate a series of IP addresses that should not be used for legitimate traffic traversing the Internet.	<i>Quick win</i>
CSC 13-2	On DMZ networks, configure monitoring systems (which may be built in to the IDS sensors or deployed as a separate technology) to record at least packet header information, and preferably full packet header and payloads of the traffic destined for or passing through the network border. This traffic should be sent to a properly configured Security Information Event Management (SIEM) or log analytics system so that events can be correlated from all devices on the network.	<i>Quick win</i>
CSC 13-3	To lower the chance of spoofed e-mail messages, implement the Sender Policy Framework (SPF) by deploying SPF records in DNS and enabling receiver-side verification in mail servers.	<i>Visibility/ Attribution</i>
CSC 13-4	Deploy network-based IDS sensors on Internet and extranet DMZ systems and networks that look for unusual attack mechanisms and detect compromise of these systems. These network-based IDS sensors may detect attacks through the use of signatures, network behaviour analysis, or other mechanisms to analyze traffic.	<i>Visibility/ Attribution</i>
CSC 13-5	Network-based IPS devices should be deployed to complement IDS by blocking known bad signature or behaviour of attacks. As attacks become automated, methods such as IDS typically delay the amount of time it takes for someone to react to an attack. A properly configured network-based IPS can provide automation to block bad traffic. When evaluating network-based IPS products, include those using techniques other than signature-based detection (such as virtual machine or sandbox-based approaches) for consideration.	<i>Visibility/ Attribution</i>
CSC 13-6	Design and implement network perimeters so that all outgoing web, file transfer protocol (FTP), and secure shell traffic to the Internet has to pass through at least one proxy on a DMZ network. The proxy should support logging individual TCP sessions; blocking specific URLs, domain names, and IP addresses to implement a black list; and applying whitelists of allowed sites that can be accessed through the proxy while blocking all other sites. Organizations should force outbound traffic to the Internet through an authenticated proxy server on the enterprise perimeter. Proxies can also be used to encrypt all traffic leaving an organization.	<i>Visibility/ Attribution</i>
CSC 13-7	Require all remote login access (including VPN, dial-up, and other forms of access that allow login to internal systems) to use two-factor authentication.	<i>Visibility/ Attribution</i>
CSC 13-8	All enterprise devices remotely logging into the internal network should be managed by the enterprise, with remote control of their configuration, installed software, and patch levels. For third-party devices (e.g. subcontractors/vendors), publish minimum security standards for access to the enterprise network and perform a security scan before allowing access.	<i>Configuration/ Hygiene</i>
CSC 13-9	Periodically scan for back-channel connections to the Internet that bypass the DMZ, including unauthorized VPN connections and dual-homed hosts connected to the enterprise network and to other networks via wireless, dial-up modems, or other mechanisms.	<i>Configuration/ Hygiene</i>

ID #	Description	Category
CSC 13-10	To limit access by an insider, untrusted subcontractor/vendor, or malware spreading on an internal network, devise internal network segmentation schemes to limit traffic to only those services needed for business use across the organization's internal network.	<i>Configuration/Hygiene</i>
CSC 13-11	To minimize the impact of an attacker pivoting between compromised systems, only allow DMZ systems to communicate with private network systems via application proxies or application-aware firewalls over approved channels.	<i>Advanced</i>
CSC 13-12	To help identify covert channels exfiltrating data through a firewall, configure the built-in firewall session tracking mechanisms included in many commercial firewalls to identify TCP sessions that last an unusually long time for the given organization and firewall device, alerting personnel about the source and destination addresses associated with these long sessions.	<i>Advanced</i>
CSC 13-13	Deploy NetFlow collection and analysis to DMZ network flows to detect anomalous activity.	<i>Configuration/Hygiene</i>

CSC 13 Procedures and Tools

The boundary defences included in this control build on Critical Control 10. The additional recommendations here focus on improving the overall architecture and implementation of both Internet and internal network boundary points. Internal network segmentation is central to this control because once inside a network, many intruders attempt to target the most sensitive machines. Usually, internal network protection is not set up to defend against an internal attacker. Setting up even a basic level of security segmentation across the network and protecting each segment with a proxy and a firewall will greatly reduce an intruder's access to the other parts of the network.

One element of this control can be implemented using free or commercial IDS and sniffers to look for attacks from external sources directed at DMZ and internal systems, as well as attacks originating from internal systems against the DMZ or Internet. Security personnel should regularly test these sensors by launching vulnerability-scanning tools against them to verify that the scanner traffic triggers an appropriate alert. The captured packets of the IDS sensors should be reviewed using an automated script each day to ensure that log volumes are within expected parameters and that the logs are formatted properly and have not been corrupted.

Additionally, packet sniffers should be deployed on DMZs to look for Hypertext Transfer Protocol (HTTP) traffic that bypasses HTTP proxies. By sampling traffic regularly, such as over a three-hour period once a week, information security personnel can search for HTTP traffic that is neither sourced by nor destined for a DMZ proxy, implying that the requirement for proxy use is being bypassed.

To identify back-channel connections that bypass approved DMZs, network security personnel can establish an Internet-accessible system to use as a receiver for testing outbound access. This system is configured with a free or commercial packet sniffer. Then, security personnel can connect a sending test system to various points on the organization's internal network, sending easily identifiable traffic to the sniffing receiver on the Internet. These packets can be generated using free or commercial tools with a payload that contains a custom file used for the test. When the packets arrive at the receiver system, the source address of the packets should be verified against acceptable DMZ addresses allowed for the organization. If source addresses are discovered that are not included in legitimate, registered DMZs, more detail can be gathered by using a traceroute tool to determine the path that packets take from the sender to the receiver system.

CSC 13 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Are all unauthorized packets entering or leaving the network detected (yes or no)?
- 2) Do all network connections to the Internet, business partners, or other third parties currently utilize inbound & outbound network filters, and Intrusion Detection Systems (IDS) (yes or no)?
- 3) How long does it take before unauthorized network packets are alerted on when passing through perimeter systems (time in minutes)?
- 4) How long does it take to apply configuration changes to block unauthorized traffic passing through perimeter systems (time in minutes)?

CSC 13 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What percentage of the organization's remote access users are not required to use two-factor authentication to remotely access the organization's network (by business unit)?
- 2) What percentage of remote business systems are not managed using the same security standards as internal network systems (by business unit)?
- 3) What percentage of the organization's internal systems are not on dedicated Virtual LANs (VLANs) that are segmented with access control lists (by business unit)?
- 4) How many events of interest have been discovered recently on the organization's network through analysis of NetFlow configured on network devices (by business unit)?

CSC 13 Effectiveness Test

To evaluate the implementation of Control 13 on a periodic basis, an evaluation team has to test boundary devices by sending packets from outside any trusted network to ensure that only authorized packets are allowed through the boundary. All other packets have to be dropped. In addition, unauthorized packets have to be sent from a trusted network to an untrusted network to make sure egress filtering is functioning properly. The evaluation team has to then verify that the systems generate an alert or e-mail notice regarding the unauthorized packets within 24 hours. It is important that the evaluation team verify that all unauthorized packets have been detected. The evaluation team has to also verify that the alert or e-mail indicating that the unauthorized traffic is now being blocked is received within one hour. The evaluation team has to verify that the system provides details of the location of each machine with this new test software, including information about the asset owner. It is also important that the evaluation team test to ensure that the device fails in a state where it does not forward traffic when it crashes or becomes flooded.

CSC 13 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

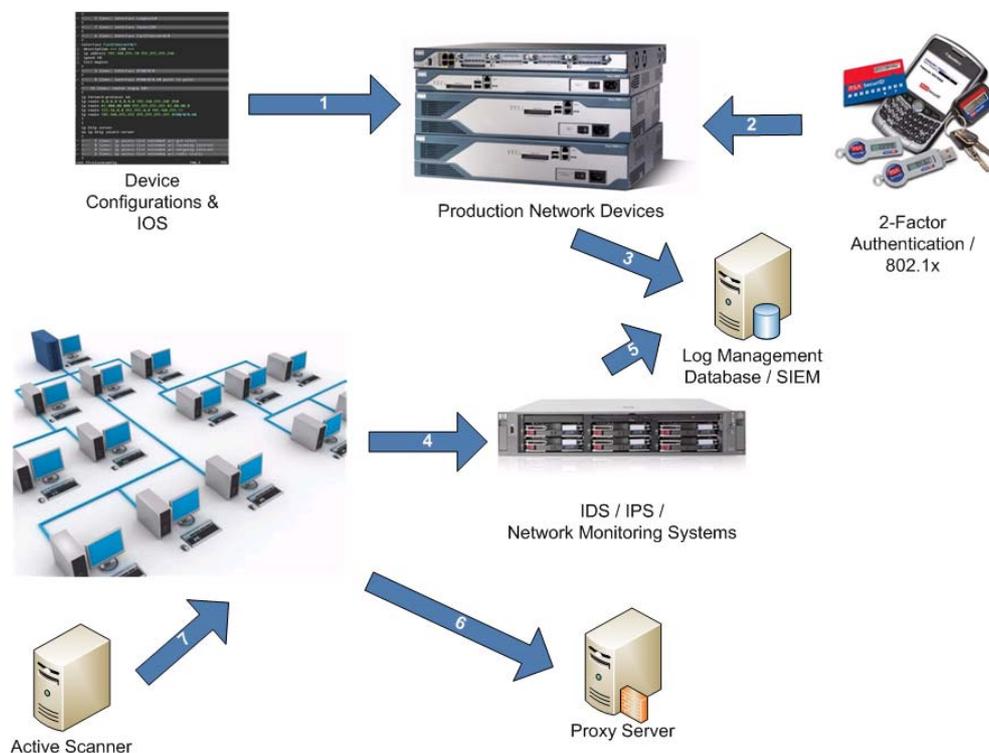

Figure 12

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case we are examining the network boundary devices and the supporting systems such as authentication servers, two-factor authentication systems, network monitoring systems, and network proxy devices. The following list of the steps in figure 12 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Hardened device configurations applied to production devices.
- Step 2: Two-factor authentication systems required for administrative access to production devices.
- Step 3: Production network devices send events to log management and correlation system.
- Step 4: Network monitoring system analyzes network traffic.
- Step 5: Network monitoring system sends events to log management and correlation system.
- Step 6: Outbound traffic passes through and is examined by network proxy devices.
- Step 7: Network systems scanned for potential weaknesses.

4.14 CSC 14: Maintenance, Monitoring, and Analysis of Audit Logs

Collect, manage, and analyze audit logs of events that could help detect, understand, or recover from an attack.

Why Is This Control Critical?

Deficiencies in security logging and analysis allow attackers to hide their location, malicious software, and activities on victim machines. Even if the victims know that their systems have been compromised, without protected and complete logging records they are blind to the details of the attack and to subsequent actions taken by the attackers. Without solid audit logs, an attack may go unnoticed indefinitely and the particular damages done may be irreversible.

Sometimes logging records are the only evidence of a successful attack. Many organizations keep audit records for compliance purposes, but attackers rely on the fact that such organizations rarely look at the audit logs, so they do not know that their systems have been compromised. Because of poor or non-existent log analysis processes, attackers sometimes control victim machines for months or years without anyone in the target organization knowing, even though the evidence of the attack has been recorded in unexamined log files.

How to Implement This Control

Table 14

ID #	Description	Category
CSC 14-1	Include at least two synchronized time sources (i.e. Network Time Protocol - NTP) from which all servers and network equipment retrieve time information on a regular basis so that timestamps in logs are consistent, and are set to UTC (Coordinate Universal Time).	Quick win
CSC 14-2	Validate audit log settings for each hardware device and the software installed on it, ensuring that logs include a date, timestamp, source addresses, destination addresses, and various other useful elements of each packet and/or transaction. Systems should record logs in a standardized format such as syslog entries or those outlined by the Common Event Expression initiative. If systems cannot generate logs in a standardized format, log normalization tools can be deployed to convert logs into such a format.	Quick win
CSC 14-3	Ensure that all systems that store logs have adequate storage space for the logs generated on a regular basis, so that log files will not fill up between log rotation intervals. The logs have to be archived and digitally signed on a periodic basis.	Quick win
CSC 14-4	Develop a log retention policy to make sure that the logs are kept for a sufficient period of time. Organizations are often compromised for several months without detection. The logs have to be kept for a longer period of time than it takes an organization to detect an attack so they can accurately determine what occurred.	Quick win

ID #	Description	Category
CSC 14-5	Have security personnel and/or system administrators run biweekly reports that identify anomalies in logs. They should then actively review the anomalies, documenting their findings.	<i>Quick win</i>
CSC 14-6	Configure network boundary devices, including firewalls, network-based IPS, and inbound and outbound proxies, to verbosely log all traffic (both allowed and blocked) arriving at the device.	<i>Visibility/ Attribution</i>
CSC 14-7	For all servers, ensure that logs are written to write-only devices or to dedicated logging servers running on separate machines from the hosts generating the event logs, lowering the chance that an attacker can manipulate logs stored locally on compromised machines.	<i>Visibility/ Attribution</i>
CSC 14-8	Deploy a SIEM (Security Incident and Event Management) or log analytic tools for log aggregation and consolidation from multiple machines and for log correlation and analysis. Using the SIEM tool, system administrators and security personnel should devise profiles of common events from given systems so that they can tune detection to focus on unusual activity, avoid false positives, more rapidly identify anomalies, and prevent overwhelming analysts with insignificant alerts.	<i>Visibility/ Attribution</i>
CSC 14-9	Monitor for service creation events and enable process tracking logs. On Windows® systems, many attackers use PsExec functionality to spread from system to system. Creation of a service is an unusual event and should be monitored closely. Process tracking is valuable for incident handling.	<i>Advanced</i>
CSC 14-10	Ensure that the log collection system does not lose events during peak activity, and that the system detects and alerts if event loss occurs (such as when volume exceeds the capacity of a log collection system). This includes ensuring that the log collection system can accommodate intermittent or restricted-bandwidth connectivity through the use of handshaking/flow control.	<i>Advanced</i>

CSC 14 Procedures and Tools

Most free and commercial operating systems, network services, and firewall technologies offer logging capabilities. Such logging should be activated, with logs sent to centralized logging servers. Firewalls, proxies, and remote access systems (VPN, dial-up, etc.) should all be configured for verbose logging, storing all the information available for logging in the event a follow-up investigation is required. Furthermore, operating systems, especially those of servers, should be configured to create access control logs when a user attempts to access resources without the appropriate privileges. To evaluate whether such logging is in place, an organization should periodically scan through its logs and compare them with the asset inventory assembled as part of Critical Control 1 in order to ensure that each managed item actively connected to the network is periodically generating logs.

Analytical programs such as SIM/SEM solutions for reviewing logs can provide value, but the capabilities employed to analyze audit logs are quite extensive, even including, importantly, just a cursory examination by a person. Actual correlation tools can make audit logs far more useful for subsequent manual inspection. Such tools can be quite helpful in identifying subtle attacks. However, these tools are neither a panacea nor a replacement for skilled information security personnel and system administrators. Even with automated log analysis tools, human expertise and intuition are often required to identify and understand attacks.

CSC 14 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Does each system log appropriately to a central log management system (yes or no)?
- 2) Does each log event generated include a date, timestamp, source address, destination address and other details about the packet (yes or no)?
- 3) If a system fails to log properly, how long does it take for an alert about the failure to be sent (time in minutes)?
- 4) If a system fails to log properly, how long does it take for enterprise personnel to receive the alert about the failure (time in minutes)?

CSC 14 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What percentage of the organization's systems do not currently have comprehensive logging enabled in accordance with the organization's standard (by business unit)?
- 2) What percentage of the organization's systems are not currently configured to centralize their logs to a central log management system (by business unit)?
- 3) How many anomalies/events of interest have been discovered in the organization's logs recently (by business unit)?

CSC 14 Effectiveness Test

To evaluate the implementation of Control 14 on a periodic basis, an evaluation team has to review the security logs of various network devices, servers, and hosts. At a minimum the following devices have to be tested: two routers, two firewalls, two switches, 10 servers, and 10 client systems. The testing team should use traffic-generating tools to send packets through the systems under analysis to verify that the traffic is logged. This analysis is done by creating controlled, benign events and determining if the information is properly recorded in the logs with key information, including a date, timestamp, source address, destination address, and other details about the packet. The evaluation team has to verify that the system generates audit logs and, if not, an alert or e-mail notice regarding the failed logging has to be sent within 24 hours. It is important that the team verify that all activity has been detected. The evaluation team has to verify that the system provides details of the location of each machine, including information about the asset owner.

CSC 14 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

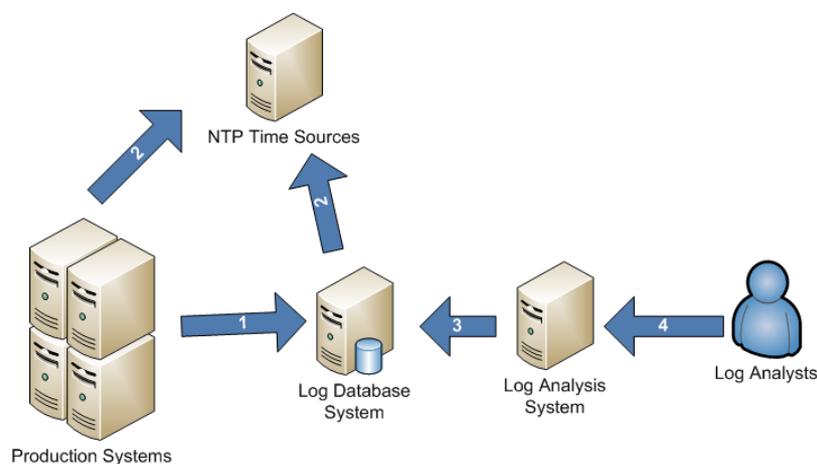

Figure 13

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining audit logs, the central log database system, the central time system, and log analysts. The following list of the steps in figure 13 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Production systems generate logs and send them to a centrally managed log database system.
- Step 2: Production systems and log database system pulls synchronize time with central time management systems.
- Step 3: Logs analyzed by a log analysis system.
- Step 4: Log analysts examine data generated by log analysis system.

4.15 CSC 15: Controlled Access Based on the Need to Know

The processes and tools used to track/control/prevent/correct secure access to critical assets (e.g. information, resources, systems) according to the formal determination of which persons, computers, and applications have a need and right to access these critical assets based on an approved classification.

Why Is This Control Critical?

Some organizations do not carefully identify and separate their most sensitive and critical assets from less sensitive, publicly accessible information on their internal networks. In many environments, internal users have access to all or most of the critical assets. Sensitive assets may also include systems that provide management and control of physical systems (e.g. SCADA). Once attackers have penetrated such a network, they can easily find and exfiltrate important information, cause physical damage, or disrupt operations with little resistance. For example, in several high-profile breaches over the past two years, attackers were able to gain access to sensitive data stored on the same servers with the same level of access as far less important data. There are also examples of using access to the corporate network to gain access to, then control over, physical assets and cause damage.

How to Implement This Control

Table 15

ID #	Description	Category
CSC 15-1	Locate any sensitive information on separated VLANs with firewall filtering. All communication of sensitive information over less-trusted networks should be encrypted.	<i>Quick win</i>
CSC 15-2	Enforce detailed audit logging for access to non-public data and special authentication for sensitive data.	<i>Visibility/ Attribution</i>
CSC 15-3	Segment the network based on the trust levels of the information stored on the servers. Whenever information flows over a network with a lower trust level, the information should be encrypted.	<i>Configuration/ Hygiene</i>
CSC 15-4	Use host-based data loss prevention (DLP) to enforce ACLs even when data is copied off a server. In most organizations, access to the data is controlled by ACLs that are implemented on the server. Once the data have been copied to a desktop system, the ACLs are no longer enforced and the users can send the data to whomever they want.	<i>Advanced</i>

CSC 15 Procedures and Tools

It is important that an organization understand what its sensitive information is, where it resides, and who needs access to it. To derive sensitivity levels, organizations need to put together a list of the key types of data and the overall importance to the organization. This analysis would be used to create an overall data classification scheme for the organization. At a base level, a data classification scheme is broken down into two levels: public (unclassified) and private (classified). Once the private information has been identified, it can then be further subdivided based on the impact it would have to the organization if it were compromised.

Once the sensitivity of the data has been identified, the data need to be traced back to business applications and the physical servers that house those applications. The network then needs to be segmented so that systems of the same sensitivity level are on the same network and segmented from systems with different trust levels. If possible, firewalls need to control access to each segment. If data are flowing over a network with a lower trust level, encryption should be used.

Job requirements should be created for each user group to determine what information the group needs access to in order to perform its jobs. Based on the requirements, access should only be given to the segments or servers that are needed for each job function. Detailed logging should be turned on for all servers in order to track access and examine situations where someone is accessing data that they should not be accessing.

CSC 15 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Can the system detect all attempts by users to access files on local systems or network-accessible file shares without the appropriate privileges (yes or no)?

- 2) How long does it take the system to generate an alert or e-mail for administrative personnel of a user inappropriately accessing the file shares (time in minutes)?

CSC 15 Automation Metrics

In order to automate the collection of relevant data from these systems, organizations should gather the following information with automated technical sensors:

- 1) What percentage of the organization's data sets have not been classified in accordance with the organization's data classification standards (by business unit)?
- 2) What percentage of sensitive data sets are not configured to require logging of access to the data set (by business unit)?
- 3) What percentage of the organization's business systems are not utilizing host based Data Loss Prevention (DLP) software applications (by business unit)?

CSC 15 Effectiveness Test

To evaluate the implementation of Control 15 on a periodic basis, the evaluation team has to create two test accounts each on 10 representative systems in the enterprise: five server machines and five client systems. For each system evaluated, one account has to have limited privileges, while the other has to have privileges necessary to create files on the systems. The evaluation team has to then verify that the non-privileged account is unable to access the files created for the other account on the system. The team has to also verify that an alert or e-mail is generated based on the attempted unsuccessful access within 24 hours. Upon completion of the test, these accounts have to be removed.

CSC 15 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

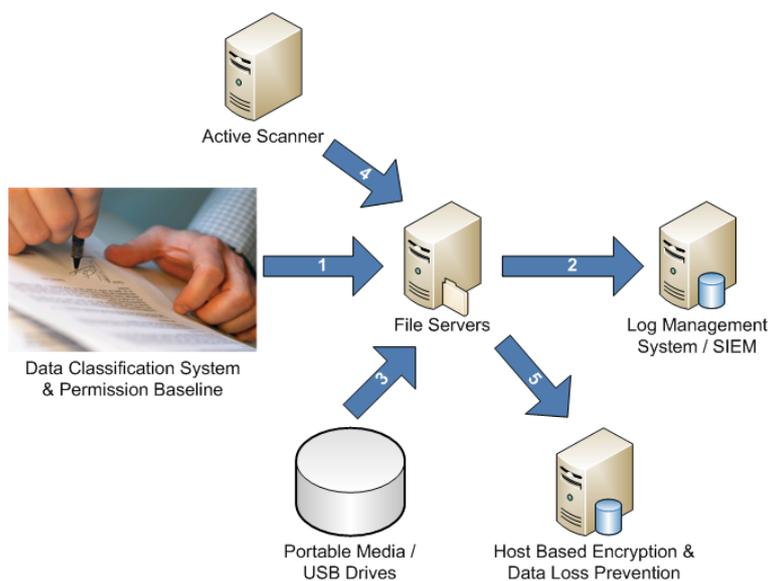

Figure 14

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, the data classification system and permission baseline is the blueprint for how authentication and access of data is controlled. The following list of the steps in figure 14 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: An appropriate data classification system and permissions baseline applied to production data systems.
- Step 2: Access appropriately logged to a log management system.
- Step 3: Proper access control applied to portable media/USB drives.

- Step 4: Active scanner validates, checks access, and checks data classification.
- Step 5: Host-based encryption and data-loss prevention validates and checks all access requests.

4.16 CSC 16: Account Monitoring and Control

Actively manage the life-cycle of system and application accounts - their creation, use, dormancy, deletion - in order to minimize opportunities for attackers to leverage them.

Why Is This Control Critical?

Attackers frequently discover and exploit legitimate but inactive user accounts to impersonate legitimate users, thereby making discovery of attacker behaviour difficult for network watchers. Accounts of contractors and employees who have been terminated and accounts formerly set up for Red Team testing (but not deleted afterwards) have often been misused in this way. Additionally, some malicious insiders or former employees have accessed accounts left behind in a system long after contract expiration, maintaining their access to an organization's computing system and sensitive data for unauthorized and sometimes malicious purposes.

How to Implement This Control

Table 16

ID #	Description	Category
CSC 16-1	Review all system accounts and disable any account that cannot be associated with a business process and owner.	Quick win
CSC 16-2	Ensure that all accounts have an expiration date associated with the account.	Quick win
CSC 16-3	Ensure that systems automatically create a report that includes a list of locked-out accounts, disabled accounts, accounts with passwords that exceed the maximum password age, and accounts with passwords that never expire. This list should be sent to the associated system administrator in a secure fashion.	Quick win
CSC 16-4	Establish and follow a process for revoking system access by disabling accounts immediately upon termination of an employee or contractor. Disabling instead of deleting accounts allows preservation of audit trails.	Quick win
CSC 16-5	Regularly monitor the use of all accounts, automatically logging off users after a standard period of inactivity.	Quick win
CSC 16-6	Configure screen locks on systems to limit access to unattended workstations.	Quick win
CSC 16-7	Monitor account usage to determine dormant accounts, notifying the user or user's manager. Disable such accounts if not needed, or document and monitor exceptions (e.g. vendor maintenance accounts needed for system recovery or continuity operations).	Quick win
CSC 16-8	Require that all non-administrator accounts have strong passwords that contain letters, numbers, and special characters, be changed at least every 90 days, have a minimal age of one day, and not be allowed to use the previous 15 passwords as a new password. These values can be adjusted based on the specific business needs of the organization.	Quick win
CSC 16-9	Use and configure account lockouts such that after a set number of failed login attempts the account is locked for a standard period of time.	Quick win
CSC 16-10	Require that managers match active employees and contractors with each account belonging to their managed staff. Security or system administrators should then disable accounts that are not assigned to active employees or contractors.	Visibility/ Attribution
CSC 16-11	Monitor attempts to access deactivated accounts through audit logging.	Visibility/ Attribution
CSC 16-12	Configure access for all accounts through a centralized point of authentication, for example Active Directory or LDAP. Configure network and security devices for centralized authentication as well.	Configuration/ Hygiene
CSC 16-13	Profile each user's typical account usage by determining normal time-of-day access and access duration. Reports should be generated that indicate users who have logged in during unusual hours or have exceeded their normal login duration. This includes flagging the use of the user's credentials from a computer other than computers on which the user generally works.	Configuration/ Hygiene

ID #	Description	Category
CSC 16-14	Require multi-factor authentication for accounts that have access to sensitive data or systems. Multi-factor authentication can be achieved using Smart cards with certificates, One Time Password (OTP) tokens, or biometrics.	<i>Advanced</i>
CSC 16-15	For authenticated access to web services within an enterprise, ensure that account usernames and passwords are passed over an encrypted channel and associated password hash files are stored securely if a centralized service is not employed.	<i>Advanced</i>
CSC 16-16	Configure all systems to use encrypted channels for the transmission of passwords over a network.	<i>Advanced</i>
CSC 16-17	Verify that all password files are encrypted or hashed and that these files cannot be accessed without root or administrator privileges. Audit all access to password files in the system.	<i>Advanced</i>

CSC 16 Procedures and Tools

Although most operating systems include capabilities for logging information about account usage, these features are sometimes disabled by default. Even when such features are present and active, they often do not provide fine-grained detail about access to the system by default. Security personnel can configure systems to record more detailed information about account access, and use home-grown scripts or third-party log analysis tools to analyze this information and profile user access of various systems.

Accounts have to also be tracked very closely. Any account that is dormant has to be disabled and eventually removed from the system. All active accounts have to be traced back to authorized users of the system, and it has to be ensured that their passwords are robust and changed on a regular basis. Users have to also be logged out of the system after a period of no activity to minimize the possibility of an attacker using their system to extract information from the organization.

CSC 16 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Does the system audit and report on valid and invalid log-ins to user accounts?
- 2) Does the system audit and report on valid and invalid log-ins to network and security device user accounts?
- 3) Does the system lock users out after five (5) invalid attempts?
- 4) Do user account passwords expire at least every 90 days?
- 5) Does the system report on dormant accounts that have not been used for a configurable period of time?
- 6) How long does it take to send an alert or e-mail to administrative personnel that the comparison report has been created (time in minutes)?

CSC 16 Automation Metrics

In order to automate the monitoring and control of user accounts, organizations should gather the following information with automated technical sensors:

- 1) How many invalid attempts to access user accounts have been detected within a period of time?
- 2) How many accounts have been locked out within a period of time?
- 3) How many attempts to gain access to password files in the system have been detected within a period of time?
- 4) Perform authorized password cracking against password files and identify the number of administrator account passwords that are cracked during the attempt. Remediate any compromised passwords immediately.
- 5) Is an automated list of user accounts on the system created daily & compared to a baseline (yes or no)?
- 6) How long does it take to send an alert or e-mail to administrative personnel that the comparison report has been created (time in minutes)?

CSC 16 Effectiveness Test

To evaluate the implementation of Control 16 on a periodic basis, the evaluation team has to attempt a variety of techniques to gain access to user accounts within the system. Each of the following tests has to be performed at least three times:

- 1) Attempt to configure weak user account passwords that are non-compliant with established policy. Verify that the system does not allow weak passwords to be used.
- 2) Attempt to re-use a user account password that was previously used for the account. Verify that the system requires unique new passwords during each update.
- 3) Attempt to capture passwords by monitoring network traffic to server resources. Remediate any instances where passwords are transmitted in clear text.
- 4) Attempt to gain access to password files stored on the system. If successful, identify whether passwords are cryptographically secured.

Each of these tests has to be performed from multiple, widely distributed systems on the organization's network in order to test the effectiveness of user account controls.

CSC 16 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

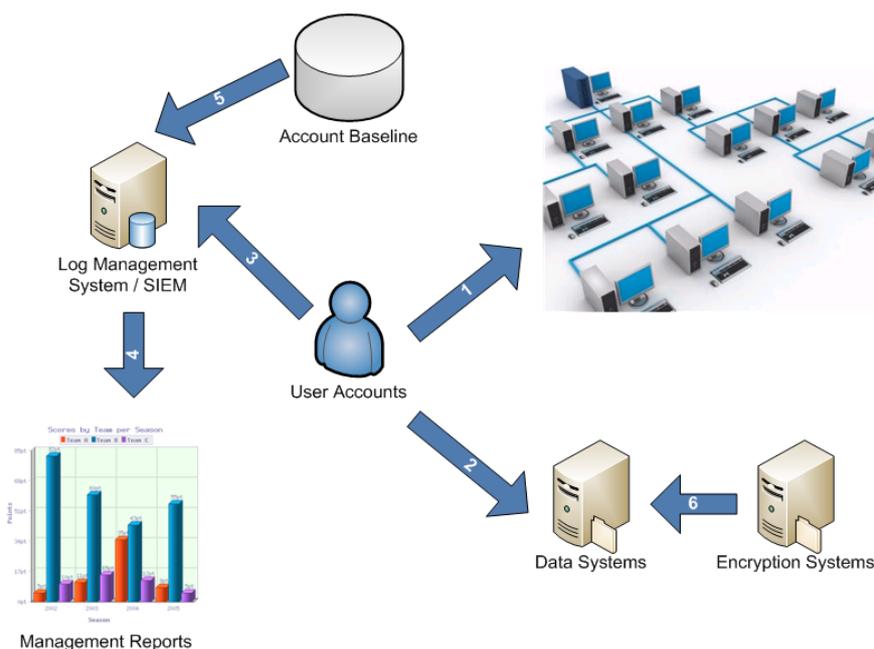

Figure 15

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining user accounts and how they interact with the data systems and the log management systems. Another key component of these systems is the reports generated for management of user accounts.

The following list of the steps in figure 15 shows how the entities work together to meet the business goal defined in this control. It also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: User accounts are properly managed on production systems.
- Step 2: User accounts are assigned proper permissions to production data sets.
- Step 3: User account access is logged to log management system.

- Step 4: Log management systems generate user account and access reports for management.
- Step 5: Account baseline information is sent to log management system.
- Step 6: Critical information is properly protected and encrypted for each user account.

4.17 CSC 17: Data Protection

The processes and tools used to prevent data exfiltration, mitigate the effects of exfiltrated data, and ensure the privacy and integrity of sensitive information.

Why Is This Control Critical?

Data resides in many places. Protection of that data is best achieved through the application of a combination of encryption, integrity protection and data loss prevention techniques. As organizations continue their move towards cloud computing and mobile access, it is important that proper care be taken to limit and report on data exfiltration while also mitigating the effects of data compromise.

The adoption of data encryption, both in transit and at rest, provides mitigation against data compromise. This is true if proper care has been taken in the processes and technologies associated with the encryption operations. An example of this is the management of cryptographic keys used by the various algorithms that protect data. The process for generation, use and destruction of keys should be based on proven processes as defined in standards such as NIST SP 800-57 [i.2].

Care should also be taken to ensure that products used within an enterprise implement well known and vetted cryptographic algorithms, as identified by NIST. Re-evaluation of the algorithms and key sizes used within the enterprise on an annual basis is also recommended to ensure that organizations are not falling behind in the strength of protection applied to their data.

For organizations that are moving data to the cloud, it is important for organizations to understand the security controls applied to data in the cloud multi-tenant environment, and determine the best course of action for application of encryption controls and security of keys. When possible, keys should be stored within secure containers such as Hardware Security Modules (HSMs).

Encrypting data provides a level of assurance that even if data is compromised, it is impractical to access the plaintext without significant resources, however controls should also be put in place to mitigate the threat of data exfiltration in the first place. Many attacks occurred across the network, while others involved physical theft of laptops and other equipment holding sensitive information. Yet, in most cases, the victims were not aware that the sensitive data were leaving their systems because they were not monitoring data outflows. The movement of data across network boundaries both electronically and physically has to be carefully scrutinized to minimize its exposure to attackers.

The loss of control over protected or sensitive data by organizations is a serious threat to business operations and a potential threat to national security. While some data are leaked or lost as a result of theft or espionage, the vast majority of these problems result from poorly understood data practices, a lack of effective policy architectures, and user error. Data loss can even occur as a result of legitimate activities such as e-Discovery during litigation, particularly when records retention practices are ineffective or non-existent.

Data loss prevention (DLP) refers to a comprehensive approach covering people, processes, and systems that identify, monitor, and protect data in use (e.g. endpoint actions), data in motion (e.g. network actions), and data at rest (e.g. data storage) through deep content inspection and with a centralized management framework. Over the last several years, there has been a noticeable shift in attention and investment from securing the network to securing systems within the network, and to securing the data itself. DLP controls are based on policy, and include classifying sensitive data, discovering that data across an enterprise, enforcing controls, and reporting and auditing to ensure policy compliance.

*How to Implement This Control***Table 17**

ID #	Description	Category
CSC 17-1	Deploy approved hard drive encryption software to mobile devices and systems that hold sensitive data.	<i>Quick win</i>
CSC 17-2	Verify that cryptographic devices and software are configured to use publicly-vetted algorithms.	<i>Quick win</i>
CSC 17-3	Perform an assessment of data to identify sensitive information that requires the application of encryption and integrity controls	<i>Quick win</i>
CSC 17-4	Review cloud provider security practices for data protection.	<i>Quick Win</i>
CSC 17-5	Deploy an automated tool on network perimeters that monitors for certain sensitive information (i.e. personally identifiable information), keywords, and other document characteristics to discover unauthorized attempts to exfiltrate data across network boundaries and block such transfers while alerting information security personnel.	<i>Visibility/ Attribution</i>
CSC 17-6	Conduct periodic scans of server machines using automated tools to determine whether sensitive data (i.e. personally identifiable information, health, credit card, and classified information) is present on the system in clear text. These tools, which search for patterns that indicate the presence of sensitive information, can help identify if a business or technical process is leaving behind or otherwise leaking sensitive information.	<i>Visibility/ Attribution</i>
CSC 17-7	Move data between networks using secure, authenticated, and encrypted mechanisms.	<i>Configuration/Hygiene</i>
CSC 17-8	If there is no business need for supporting such devices, configure systems so that they will not write data to USB tokens or USB hard drives. If such devices are required, enterprise software should be used that can configure systems to allow only specific USB devices (based on serial number or other unique property) to be accessed, and that can automatically encrypt all data placed on such devices. An inventory of all authorized devices has to be maintained.	<i>Configuration/Hygiene</i>
CSC 17-9	Use network-based DLP solutions to monitor and control the flow of data within the network. Any anomalies that exceed the normal traffic patterns should be noted and appropriate action taken to address them.	<i>Configuration/Hygiene</i>
CSC 17-10	Only allow approved Certificate Authorities (CAs) to issue certificates within the enterprise; Review and verify each CAs Certificate Practices Statement (CPS) and Certificate Policy (CP).	<i>Configuration/Hygiene</i>
CSC 17-11	Perform an annual review of algorithms and key lengths in use for protection of sensitive data.	<i>Configuration/Hygiene</i>
CSC 17-12	Monitor all traffic leaving the organization and detect any unauthorized use of encryption. Attackers often use an encrypted channel to bypass network security devices. Therefore it is essential that organizations be able to detect rogue connections, terminate the connection, and remediate the infected system.	<i>Advanced</i>
CSC 17-13	Block access to known file transfer and e-mail exfiltration websites.	<i>Advanced</i>
CSC 17-14	Define roles and responsibilities related to management of encryption keys within the enterprise; define processes for lifecycle.	<i>Advanced</i>
CSC 17-15	Where applicable, implement Hardware Security Modules (HSMs) for protection of private keys (e.g. for sub CAs) or Key Encryption Keys.	<i>Advanced</i>

CSC 17 Procedures and Tools

Commercial tools are available to support enterprise management of encryption and key management within an enterprise and include the ability to support implementation of encryption controls within cloud and mobile environments.

Definition of lifecycle processes and roles and responsibilities associated with key management should be undertaken by each organization.

Commercial DLP solutions are available to look for exfiltration attempts and detect other suspicious activities associated with a protected network holding sensitive information. Organizations deploying such tools should carefully inspect their logs and follow up on any discovered attempts, even those that are successfully blocked, to transmit sensitive information out of the organization without authorization.

CSC 17 Effectiveness Metrics

In order to test the effectiveness of the automated implementation of this control, organizations should measure the following:

- 1) Does the system identify and report on unauthorized data being exfiltrated, whether via network file transfers or removable media?
- 2) Does the system identify the attachment of unencrypted USB tokens and require encryption of tokens?
- 3) Does the system store cryptographic key material securely?
- 4) Does the system use only NIST approved encryption algorithms?
- 5) Within one hour of a data exfiltration event or attempt, enterprise administrative personnel have to be alerted by the appropriate monitoring system.
- 6) Do alerts notifying of data exfiltration also note the system and location where the event or attempt occurred?
- 7) Are the systems able to identify the location, department, and other critical details about where the sensitive data originated from (yes or no)?
- 8) How long does it take before a data leakage risk has been remediated from the time it was detected (time in minutes)?

CSC 17 Automation Metrics

In order to automate the protection of data using cryptography and DLP functions, organizations should gather the following information with automated technical sensors:

- 1) How many unauthorized data exfiltration attempts have been detected within a period of time by DLP software?
- 2) How many plaintext instances of sensitive data have been detected within a period by automated scanning software?
- 3) How many attempts to access known file transfer and e-mail exfiltration websites have been detected within a period of time?

CSC 17 Effectiveness Test

To evaluate the implementation of Control 17 on a periodic basis, the evaluation team has to attempt to move test data sets that trigger DLP systems but do not contain sensitive data outside of the trusted computing environment via both network file transfers and removable media. Each of the following tests has to be performed at least three times:

- Attempt to transfer large data sets across network boundaries from an internal system.
- Attempt to transfer plaintext test data sets of personally identifiable information (that trigger DLP systems but do not contain sensitive data) across network boundaries from an internal system (using multiple keywords specific to the business).
- Attempt to transfer encrypted test data sets across network boundaries from an internal system to identify if the exfiltration is reported.
- Attempt to maintain a persistent network connection for at least 10 hours across network boundaries between an internal and external system, even though little data may be exchanged.
- Attempt to maintain a network connection across network boundaries using an anomalous service port number between an internal and external system.
- Insert a USB token into an organization system and attempt to transfer example test data to the USB device.

Each of these tests has to be performed from multiple, widely distributed systems on the organization's network in order to test the effectiveness of the monitoring systems. Once each of these events has occurred, the time it takes for enterprise staff to respond to the event has to be recorded.

CSC 17 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

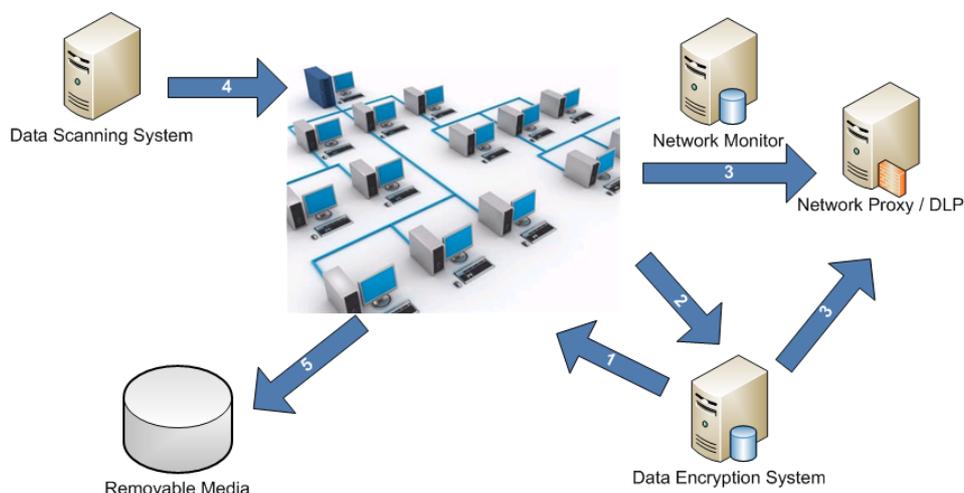

Figure 16

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the flow of information in and out of the organization in an attempt to limit potential data loss via network or removable media sources. The following list of the steps in figure 16 shows how the entities work together to meet the business goal defined in this control. It also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Data encryption system ensures that appropriate hard disks are encrypted.
- Step 2: Sensitive network traffic encrypted.
- Step 3: Data connections monitored at the network's perimeter by monitoring systems.
- Step 4: Stored data scanned to identify where sensitive information is stored.
- Step 5: Offline media encrypted.

4.18 CSC 18: Incident Response and Management

Protect the organization's information, as well as its reputation, by developing and implementing an incident response infrastructure (e.g. plans, defined roles, training, communications, management oversight) for quickly discovering an attack and then effectively containing the damage, eradicating the attacker's presence, and restoring the integrity of the network and systems.

Why Is This Control Critical?

Cyber incidents are now just part of our way of life. Even large, well-funded, and technically sophisticated enterprises struggle to keep up with the frequency and complexity of attacks. The question of a successful cyber-attack against an enterprise is not "if" but "when".

When an incident occurs, it is too late to develop the right procedures, reporting, data collection, management responsibility, legal protocols, and communications strategy that will allow the enterprise to successfully understand, manage, and recover. Without an incident response plan, an organization may not discover an attack in the first place, or, if the attack is detected, the organization may not follow good procedures to contain damage, eradicate the attacker's presence, and recover in a secure fashion. Thus, the attacker may have a far greater impact, causing more damage, infecting more systems, and possibly exfiltrate more sensitive data than would otherwise be possible were an effective incident response plan in place.

*How to Implement This Control***Table 18**

ID #	Description	Category
CSC 18-1	Ensure that there are written incident response procedures that include a definition of personnel roles for handling incidents. The procedures should define the phases of incident handling.	<i>Quick win</i>
CSC 18-2	Assign job titles and duties for handling computer and network incidents to specific individuals.	<i>Quick win</i>
CSC 18-3	Define management personnel who will support the incident handling process by acting in key decision-making roles.	<i>Quick win</i>
CSC 18-4	Devise organization-wide standards for the time required for system administrators and other personnel to report anomalous events to the incident handling team, the mechanisms for such reporting, and the kind of information that should be included in the incident notification. This reporting should also include notifying the appropriate Community Emergency Response Team in accordance with all legal or regulatory requirements for involving that organization in computer incidents.	<i>Quick win</i>
CSC 18-5	Assemble and maintain information on third-party contact information to be used to report a security incident (i.e. maintain an e-mail address of security@organization.com or have a web page http://organization.com/security).	<i>Quick win</i>
CSC 18-6	Publish information for all personnel, including employees and contractors, regarding reporting computer anomalies and incidents to the incident handling team. Such information should be included in routine employee awareness activities.	<i>Quick win</i>
CSC 18-7	Conduct periodic incident scenario sessions for personnel associated with the incident handling team to ensure that they understand current threats and risks, as well as their responsibilities in supporting the incident handling team.	<i>Configuration/ Hygiene</i>

CSC 18 Procedures and Tools

After defining detailed incident response procedures, the incident response team should engage in periodic scenario-based training, working through a series of attack scenarios fine-tuned to the threats and vulnerabilities the organization faces. These scenarios help ensure that team members understand their role on the incident response team and also help prepare them to handle incidents.

A full treatment of this topic is beyond the scope of the Critical Security Controls. However, the actions in CSC 18 provide specific, high-priority steps that can improve enterprise security, and should be a part of any comprehensive incident and response plan.

CSC 18 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

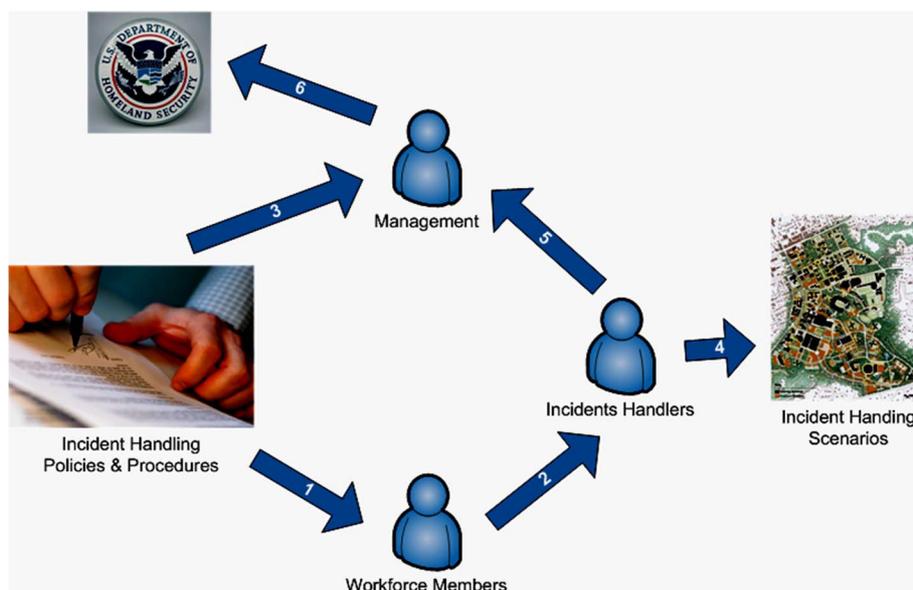

Figure 17

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the incident handling process and how prepared organizations are in the event that an incident occurs. The following list of the steps in figure 17 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Incident handling policies and procedures educate workforce members as to their responsibilities during an incident.
- Step 2: Some workforce members designated as incident handlers.
- Step 3: Incident handling policies and procedures educate management as to their responsibilities during an incident.
- Step 4: Incident handlers participate in incident handling scenario tests.
- Step 5: Incident handlers report incidents to management.
- Step 6: The organization's management reports incidents to outside law enforcement and the appropriate computer emergency response team, if necessary.

4.19 CSC 19: Secure Network Engineering

Make security an inherent attribute of the enterprise by specifying, designing, and building-in features that allow high confidence systems operations while denying or minimizing opportunities for attackers.

Why Is This Control Critical?

System or security designers rarely get to start from scratch and build in all of the security features they might want. And even if they did, systems constantly evolve, new business imperatives appear, attackers develop new techniques, and new technologies emerge to complicate the security problem. In such an environment, attackers take advantage of missing security features, time gaps in deploying new defences or moving information, and the "seams" between defensive controls. Defenders are quickly overwhelmed with new operational requirements, managing tools and changes, new information, and "fire-fighting".

*How to Implement This Control***Table 19**

ID #	Description	Category
CSC 19-1	Design the network using a minimum of a three-tier architecture (DMZ, middleware, and private network). Any system accessible from the Internet should be on the DMZ, but DMZ systems should never contain sensitive data. Any system with sensitive data should reside on the private network and never be directly accessible from the Internet. DMZ systems should communicate with private network systems through an application proxy residing on the middleware tier.	<i>Quick win</i>
CSC 19-2	To support rapid response and shunning of detected attacks, engineer the network architecture and its corresponding systems for rapid deployment of new access control lists, rules, signatures, blocks, blackholes, and other defensive measures.	<i>Configuration/Hygiene</i>
CSC 19-3	Deploy domain name systems (DNS) in a hierarchical, structured fashion, with all internal network client machines configured to send requests to intranet DNS servers, not to DNS servers located on the Internet. These internal DNS servers should be configured to forward requests they cannot resolve to DNS servers located on a protected DMZ. These DMZ servers, in turn, should be the only DNS servers allowed to send requests to the Internet.	<i>Visibility/Attribution</i>
CSC 19-4	Segment the enterprise network into multiple, separate trust zones to provide more granular control of system access and additional intranet boundary defences.	<i>Configuration/Hygiene</i>

CSC 19 Procedures and Tools

To help ensure a consistent, defensible network, the architecture of each network should be based on a template that describes the network's overall layout and the services it provides. Organizations should prepare diagrams for each of their networks that show network components such as routers, firewalls, and switches, along with significant servers and groups of client machines.

Although the Critical Security Controls overall provide many specific, high-priority steps that will improve enterprise security, a comprehensive treatment of Secure Network Engineering is beyond the scope of the present document. In CSC 19, we describe capabilities that should be built-in to any security architecture.

CSC 19 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

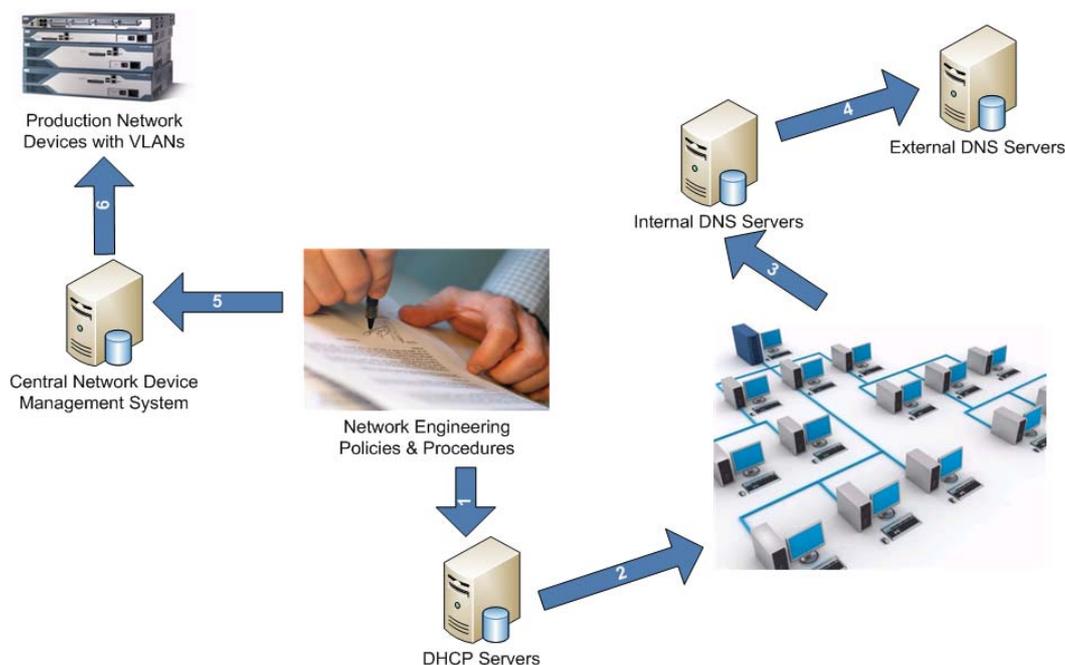

Figure 18

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining the network engineering process and evaluating the controls that work together in order to create a secure and robust network architecture. The following list of the steps in figure 18 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Network engineering policies and procedures dictate how network systems function to include dynamic host configuration protocol (DHCP) servers.
- Step 2: DHCP servers provide IP addresses to systems on the network.
- Step 3: Network devices perform DNS lookups to internal DNS servers.
- Step 4: Internal DNS servers perform DNS lookups to external DNS servers.
- Step 5: Network engineering policies and procedures dictate how a central network management system functions.
- Step 6: Central network management systems configure network devices.

4.20 CSC 20: Penetration Tests and Red Team Exercises

Test the overall strength of an organization's defences (the technology, the processes, and the people) by simulating the objectives and actions of an attacker.

Why Is This Control Critical?

Attackers often exploit the gap between good defensive designs and intentions and implementation or maintenance. Examples include: the time window between announcement of a vulnerability, the availability of a vendor patch, and actual installation on every machine; well-intentioned policies which have no enforcement mechanism (especially those intended to restrict risky human actions); failure to apply good configurations and other practices to the entire enterprise, or to machines that come in-and-out of the network; and failure to understand the interaction among multiple defensive tools, or with normal system operations that have security implications.

In addition, successful defence requires a comprehensive program of technical defences, good policy and governance, and appropriate action by people. In a complex environment where technology is constantly evolving, and new attacker tradecraft appears regularly, organizations should periodically test their defences to identify gaps and to assess their readiness.

Penetration testing starts from the identification and assessment of vulnerabilities that can be identified in the enterprise. It complements this by designing and executing tests that demonstrate specifically how an adversary can either subvert the organization's security goals (e.g. the protection of specific Intellectual Property) or achieve specific adversarial objectives (e.g. establishment of a covert Command and Control infrastructure). The result provides deeper insight, through demonstration, into the business risks of various vulnerabilities.

Red Team exercises take a comprehensive approach at the full spectrum of organization policies, processes, and defences in order to improve organizational readiness, improve training for defensive practitioners, and inspect current performance levels. Independent Red Teams can provide valuable and objective insights about the existence of vulnerabilities and the efficacy of defences and mitigating controls already in place and even of those planned for future implementation.

How to Implement This Control

Table 20

ID #	Description	Category
CSC 20-1	Conduct regular external and internal penetration tests to identify vulnerabilities and attack vectors that can be used to exploit enterprise systems successfully. Penetration testing should occur from outside the network perimeter (i.e. the Internet or wireless frequencies around an organization) as well as from within its boundaries (i.e. on the internal network) to simulate both outsider and insider attacks.	<i>Quick win</i>
CSC 20-2	Any user or system accounts used to perform penetration testing, should be controlled and monitored to make sure they are only being used for legitimate purposes, and are removed or restored to normal function after testing is over.	<i>Quick win</i>
CSC 20-3	Perform periodic Red Team exercises to test organizational readiness to identify and stop attacks or to respond quickly and effectively.	<i>Visibility/ Attribution</i>
CSC 20-4	Include tests for the presence of unprotected system information and artifacts that would be useful to attackers, including network diagrams, configuration files, older penetration test reports, e-mails or documents containing passwords or other information critical to system operation.	<i>Visibility/ Attribution</i>
CSC 20-5	Plan clear goals of the penetration test itself with blended attacks in mind, identifying the goal machine or target asset. Many APT-style attacks deploy multiple vectors-often social engineering combined with web or network exploitation. Red Team manual or automated testing that captures pivoted and multi-vector attacks offers a more realistic assessment of security posture and risk to critical assets.	<i>Visibility/ Attribution</i>
CSC 20-6	Use vulnerability scanning and penetration testing tools in concert. The results of vulnerability scanning assessments should be used as a starting point to guide and focus penetration testing efforts.	<i>Configuration/ Hygiene</i>
CSC 20-7	Devise a scoring method for determining the results of Red Team exercises so that results can be compared over time.	<i>Advanced</i>
CSC 20-8	Create a test bed that mimics a production environment for specific penetration tests and Red Team attacks against elements that are not typically tested in production, such as attacks against supervisory control and data acquisition and other control systems.	<i>Advanced</i>

CSC 20 Procedures and Tools

Penetration testing and Red Teaming only provide significant value when basic defensive measures have already been put into place, and when they are performed as part of a comprehensive, ongoing program of security management and improvement. These are often specified and required by formal Risk Management Frameworks and processes.

Each organization should define a clear scope and rules of engagement for penetration testing and Red Team analyses. The scope of such projects should include, at a minimum, systems with the organization's highest value information and production processing functionality. Other lower-value systems may also be tested to see if they can be used as pivot points to compromise higher-value targets. The rules of engagement for penetration tests and Red Team analyses should describe, at a minimum, times of day for testing, duration of tests, and the overall test approach.

A full treatment of this topic is beyond the scope of the Critical Security Controls. However, the actions in CSC 20 provide specific, high-priority steps that can improve enterprise security, and should be a part of any comprehensive penetration testing and Red Team program.

CSC 20 System Entity Relationship Diagram

Organizations will find that by diagramming the entities necessary to fully meet the goals defined in this control, it will be easier to identify how to implement them, test the controls, and identify where potential failures in the system might occur.

**Figure 19**

A control system is a device or set of devices used to manage, command, direct, or regulate the behaviour of other devices or systems. In this case, we are examining red team and penetration exercises and how those efforts can be valuable to enterprise personnel when identifying which vulnerabilities are present in the organization. The following list of the steps in figure 19 shows how the entities work together to meet the business goal defined in this control. The list also delineates each of the process steps in order to help identify potential failure points in the overall control.

- Step 1: Penetration testers perform penetration tests of production systems.
- Step 2: Automated pen-testing tools perform penetration tests of production systems.
- Step 3: Automated pen-testing tools inform penetration tester of vulnerabilities discovered.
- Step 4: Penetration testers perform more extensive penetration tests of test lab systems.
- Step 5: Auditors evaluate and inspect the work performed by automated pen-testing tools.
- Step 6: Auditors evaluate and inspect the work performed by penetration testers.
- Step 7: Penetration testers generate reports and statistics about the vulnerabilities that have been discovered.

Annex A: Attack Types

The following Attack Types were the primary ones considered when developing the Critical Security Controls. Each is listed with the most relevant and direct Critical Security Controls (by number) to help block, detect, or manage this problem.

Attack Summary	Critical Security Control
Attackers continually scan for new, unprotected systems, including test or experimental systems, and exploit such systems to gain control of them.	1
Attackers distribute hostile content on Internet-accessible (and sometimes internal) websites that exploit unpatched and improperly secured client software running on victim machines.	2, 3
Attackers continually scan for vulnerable software and exploit it to gain control of target machines.	2, 4
Attackers use currently infected or compromised machines to identify and exploit other vulnerable machines across an internal network.	2, 10
Attackers exploit weak default configurations of systems that are more geared to ease of use than security.	3, 10
Attackers exploit new vulnerabilities on systems that lack critical patches in organizations that do not know that they are vulnerable because they lack continuous vulnerability assessments and effective remediation.	4, 5
Attackers compromise target organizations that do not exercise their defences to determine and continually improve their effectiveness.	4, 5, 11, 20
Attackers use malicious code to gain and maintain control of target machines, capture sensitive data, and then spread it to other systems, sometimes wielding code that disables or dodges signature-based anti-virus tools.	5, 15, 17
Attackers scan for remotely accessible services on target systems that are often unneeded for business activities, but provide an avenue of attack and compromise of the organization.	5, 10, 11
Attackers exploit weak application software, particularly web applications, through attack vectors such as SQL injection, cross-site scripting, and similar tools.	6, 20
Attackers exploit wireless access points to gain entry into a target organization's internal network, and exploit wireless client systems to steal sensitive information.	7
Attackers exploit users and system administrators via social engineering scams that work because of a lack of security skills and awareness.	9, 12, 16
Attackers exploit and infiltrate through network devices whose security configuration has been weakened over time by granting, for specific short-term business needs, supposedly temporary exceptions that are never removed.	10, 13
Attackers trick a user with an administrator-level account into opening a phishing-style e-mail with an attachment or surfing to the attacker's content on an Internet website, allowing the attacker's malicious code or exploit to run on the victim machine with full administrator privileges.	9, 12
Attackers exploit boundary systems on Internet-accessible DMZ networks, and then pivot to gain deeper access on internal networks.	13, 19
Attackers exploit poorly designed network architectures by locating unneeded or unprotected connections, weak filtering, or a lack of separation of important systems or business functions.	13, 19
Attackers operate undetected for extended periods of time on compromised systems because of a lack of logging and log review.	14
Attackers gain access to sensitive documents in an organization that does not properly identify and protect sensitive information or separate it from non-sensitive information.	15, 17
Attackers compromise inactive user accounts left behind by temporary workers, contractors, and former employees, including accounts left behind by the attackers themselves who are former employees.	16
Attackers escalate their privileges on victim machines by launching password guessing, password cracking, or privilege escalation exploits to gain administrator control of systems, which is then used to propagate to other victim machines across an enterprise.	12, 16
Attackers gain access to internal enterprise systems and gather and exfiltrate sensitive information without detection by the victim organization.	17
Attackers compromise systems and alter important data, potentially jeopardizing organizational effectiveness via polluted information.	15, 17
Attackers operate undiscovered in organizations without effective incident-response capabilities, and when the attackers are discovered, the organizations often cannot properly contain the attack, eradicate the attacker's presence, or recover to a secure production state.	18
