Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (http://ipr.etsi.org).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by ETSI 3rd Generation Partnership Project (3GPP).

The present document may refer to technical specifications or reports using their 3GPP identities, UMTS identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables.

The cross reference between GSM, UMTS, 3GPP and ETSI identities can be found under <u>http://webapp.etsi.org/key/queryform.asp</u>.

Modal verbs terminology

In the present document "shall", "shall not", "should", "should not", "may", "need not", "will", "will not", "can" and "cannot" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.

Foreword

This Technical Specification has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

- x the first digit:
 - 1 presented to TSG for information;
 - 2 presented to TSG for approval;
 - 3 or greater indicates TSG approved document under change control.
- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
- z the third digit is incremented when editorial only changes have been incorporated in the document.

1 Scope

The present document specifies the security architecture, i.e., the security features and the security mechanisms for the Evolved Packet System and the Evolved Packet Core, and the security procedures performed within the evolved Packet System (EPS) including the Evolved Packet Core (EPC) and the Evolved UTRAN (E-UTRAN).

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document *in the same Release as the present document*.

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in TR 21.905 [1], in TS 33.102 [4] and the following apply. A term defined in the present document takes precedence over the definition of the same term, if any, in TR 21.905 [1].

Access Security Management Entity: entity which receives the top-level keys in an access network from the HSS. For E-UTRAN access networks, the role of the ASME is assumed by the MME

Activation of security context: the process of taking into use a security context.

Authentication data: Data that is part of a security context or of authentication vectors.

Chaining of K_{eNB}: derivation of a new K_{eNB} from another K_{eNB} (i.e., at cell handover)

Current EPS security context: The security context which has been activated most recently. Note that a current EPS security context originating from either a mapped or native EPS security context may exist simultaneously with a native non-current EPS security context.

ECM-CONNECTED state: This is as defined in TS 23.401 [2]. The term ECM-CONNECTED state corresponds to the term EMM-CONNECTED mode used in TS 24.301 [9].

ECM-IDLE state: As defined in TS 23.401 [2]. The term ECM-IDLE state corresponds to the term EMM-IDLE mode used in TS 24.301 [9].

EPS-Authentication Vector: KASME, RAND, AUTN, XRES

EPS security context: A state that is established locally at the UE and a serving network domain. At both ends "EPS security context data" is stored, that consists of the EPS NAS security context, and the EPS AS security context.

NOTE 1: An EPS security context has type 'mapped', 'full native' or 'partial native'. Its state can either be 'current' or 'non-current'. A context can be of one type only and be in one state at a time. The state of a particular context type can change over time. A partial native context can be transformed into a full native. No other type transformations are possible.

EPS AS security context: the cryptographic keys at AS level with their identifiers, the Next Hop parameter NH, the Next Hop Chaining Counter parameter NCC used for next hop access key derivation, the identifiers of the selected AS

level cryptographic algorithms and counters used for replay protection. Note that the EPS AS security context only exists when cryptographically protected radio bearers are established and is otherwise void.

NOTE 2: NH and NCC need to be stored also at the MME during connected mode.

EPS NAS security context: This context consists of K_{ASME} with the associated key set identifier, the UE security capabilities, and the uplink and downlink NAS COUNT values. In particular, separate pairs of NAS COUNT values are used for each EPS NAS security contexts, respectively. The distinction between native and mapped EPS security contexts also applies to EPS NAS security contexts. The EPS NAS security context is called 'full' if it additionally contains the keys K_{NASint} and K_{NASenc} and the identifiers of the selected NAS integrity and encryption algorithms.

Full native EPS security context: A native EPS security context for which the EPS NAS security context is full according to the above definition. A full native EPS security context is either in state 'current' or state 'non-current'.

Forward security: In the context of K_{eNB} key derivation, forward security refers to the property that, for an eNB with knowledge of a K_{eNB} , shared with a UE, it shall be computationally infeasible to predict any future K_{eNB} , that will be used between the same UE and another eNB. More specifically, n hop forward security refers to the property that an eNB is unable to compute keys that will be used between a UE and another eNB to which the UE is connected after n or more handovers (n=1 or 2).

Legacy security context: A security context which has been established according to TS 33.102 [4].

Mapped security context: Security context created by converting the current security context in the source system to a security context for the target system in inter-system mobility, e.g., UMTS keys created from EPS keys. The EPS NAS security context of a mapped security context is full and current.

Native EPS security context: An EPS security context whose K_{ASME} was created by a run of EPS AKA.

Non-current EPS security context: A native EPS security context that is not the current one. A non-current EPS security context may be stored along with a current EPS security context in the UE and the MME. A non-current EPS security context does not contain an EPS AS security context. A non-current EPS security context is either of type 'full native' or of type 'partial native'.

Partial native EPS security context: A partial native EPS security context consists of K_{ASME} with the associated key set identifier, the UE security capabilities, and the uplink and downlink NAS COUNT values, which are initially set to zero before the first NAS SMC procedure for this security context. A partial native EPS security context is created by an EPS AKA, for which no corresponding successful NAS SMC has been run. A partial native context is always in state 'non-current'.

Re-derivation of NAS keys: derivation of new NAS keys from the same K_{ASME} but including different algorithms (and no freshness parameter)

Refresh of KeNB: derivation of a new KeNB from the same KASME and including a freshness parameter

Re-keying of K_{eNB}: derivation of a new K_{eNB} from a new K_{ASME} in ECM-CONNECTED (i.e., . to activate a partial native EPS security context, or to re-activate a non-current full EPS security context)

Re-keying of NAS keys: derivation of new NAS keys from a new KASME

UE security capabilities: The set of identifiers corresponding to the ciphering and integrity algorithms implemented in the UE. This includes capabilities for EPS AS and NAS, and includes capabilities for UTRAN and GERAN if these access types are supported by the UE.

UE EPS security capabilities: The UE security capabilities for EPS AS and NAS.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

Concatenation
Concatenation

 \oplus Bitwise Exclusive Or (XOR) operation

3.3 Abbreviations

For the purposes of the present document, the abbreviations given in TR 21.905 [1] and the following apply. An abbreviation defined in the present document takes precedence over the definition of the same abbreviation, if any, in TR 21.905 [1].

AES	Advanced Encryption Standard
AK	Anonymity Key
AKA	Authentication and Key Agreement
AMF	Authentication Management Field
AN	Access Network
AS	Access Stratum
AUTN	Authentication token
AV	Authentication Vector
ASME	Access Security Management Entity
Cell-ID	Cell Identity as used in TS 36.331 [21]
СК	Cipher Key
CKSN	Cipher Key Sequence Number
C-RNTI	Cell RNTI as used in TS 36.331 [21]
DoS	Denial of Service
EARFCN-DL	E-UTRA Absolute Radio Frequency Channel Number-Down Link
ECM	EPS Connection Management
EEA	EPS Encryption Algorithm
EIA	EPS Integrity Algorithm
eKSI	Key Set Identifier in E-UTRAN
EMM	EPS Mobility Management
eNB	Evolved Node-B
EPC	Evolved Packet Core
EPS	Evolved Packet System
EPS-AV	EPS authentication vector
E-UTRAN	Evolved UTRAN
GERAN	GSM EDGE Radio Access Network
GUTI	Globally Unique Temporary Identity
HE	Home Environment
HFN	Hyper Frame Number
HO	Hand Over
HSS	Home Subscriber Server
IK	Integrity Key
IKE	Internet Key Exchange
IMEI	International Mobile Station Equipment Identity
IMEISV	International Mobile Station Equipment Identity and Software Version number
IMSI	International Mobile Subscriber Identity
IRAT	Inter-Radio Access Technology
ISR	Idle Mode Signaling Reduction
KDF	Key Derivation Function
KSI	Key Set Identifier
LSB	Least Significant Bit
LSM	Limited Service Mode
MAC-I	Message Authentication Code for Integrity (terminology of TS36.323 [12])
MACT	Message Authentication Code T used in AES CMAC calculation
ME	Mobile Equipment
MME	Mobility Management Entity
MS	Mobile Station
MSC	Mobile Switching Center
MSIN	Mobile Station Identification Number
NAS NAS MAC	Non Access Stratum
NAS-MAC	Message Authentication Code for NAS for Integrity (called MAC in TS24.301 [9])
NCC	Next hop Chaining Counter
NH PCI	Next Hop Physical Call Identity as used in TS 36 331 [21]
PCI PLMN	Physical Cell Identity as used in TS 36.331 [21] Public Land Mobile Network
I LAVIIN	I done Land WOOR INCOME

PRNG	Pseudo Random Number Generator
P-TMSI	Packet- Temporary Mobile Subscriber Identity
PDCP	Packet Data Convergence Protocol
RAND	RANDom number
RAU	Routing Area Update
RRC	Radio Resource Control
SGSN	Serving GPRS Support Node
SIM	Subscriber Identity Module
SMC	Security Mode Command
SN	Serving Network
SN id	Serving Network identity
SQN	Sequence Number
SRB	Source Route Bridge
SRVCC	Single Radio Voice Call Continuity
S-TMSI	S-Temporary Mobile Subscriber Identity
TAI	Tracking Area Identity
TAU	Tracking Area Update
UE	User Equipment
UEA	UMTS Encryption Algorithm
UIA	UMTS Integrity Algorithm
UICC	Universal Integrated Circuit Card
UMTS	Universal Mobile Telecommunication System
UP	User Plane
USIM	Universal Subscriber Identity Module
UTRAN	Universal Terrestrial Radio Access Network
XRES	Expected Response

3.4 Conventions

All data variables in the present document are presented with the most significant substring on the left hand side and the least significant substring on the right hand side. A substring may be a bit, byte or other arbitrary length bitstring. Where a variable is broken down into a number of substrings, the leftmost (most significant) substring is numbered 0, the next most significant is numbered 1, and so on through to the least significant.

4 Overview of Security Architecture

Figure 4-1 gives an overview of the complete security architecture.

Figure 4-1: Overview of the security architecture

Five security feature groups are defined. Each of these feature groups meets certain threats and accomplishes certain security objectives:

- Network access security (I): the set of security features that provide users with secure access to services, and which in particular protect against attacks on the (radio) access link.
- Network domain security (II): the set of security features that enable nodes to securely exchange signalling data, user data (between AN and SN and within AN), and protect against attacks on the wireline network.
- User domain security (III): the set of security features that secure access to mobile stations.
- **Application domain security (IV):** the set of security features that enable applications in the user and in the provider domain to securely exchange messages.
- Visibility and configurability of security (V): the set of features that enables the user to inform himself whether a security feature is in operation or not and whether the use and provision of services should depend on the security feature.

5 Security Features

5.1 User-to-Network security

5.1.1 User identity and device confidentiality

User identity confidentiality is as defined by TS 33.102 [4] subclause 5.1.1

From subscriber's privacy point of view, the MSIN, the IMEI, and the IMEISV should be confidentiality protected.

The UE shall provide its equipment identifier IMEI or IMEISV to the network, if the network asks for it in an integrity-protected request.

The IMEI and IMEISV shall be securely stored in the terminal.

The UE shall not send IMEI or IMEISV to the network on a network request before the NAS security has been activated.

NOTE 1: When the UE has no IMSI, no valid GUTI, or no valid P-TMSI during emergency attach, the IMEI is included before the NAS security has been activated.

The IMEI or IMEISV shall be sent in the NAS protocol.

NOTE 2: In some cases, e.g., the very first attach procedure, MSIN has to be sent to network in cleartext. When NAS confidentiality protection is beyond an operator option, IMEI and IMEISV can not be confidentiality protected.

5.1.2 Entity authentication

Entity authentication is as defined by TS 33.102 [4] subclause 5.1.2

5.1.3 User data and signalling data confidentiality

5.1.3.1 Ciphering requirements

Ciphering may be provided to RRC-signalling to prevent UE tracking based on cell level measurement reports, handover message mapping, or cell level identity chaining. RRC signalling confidentiality is an operator option.

Synchronization of the input parameters for ciphering shall be ensured for the protocols involved in the ciphering.

The NAS signalling may be confidentiality protected. NAS signalling confidentiality is an operator option.

NOTE 1: RRC and NAS signalling confidentiality protection is recommended to be used.

When authentication of the credentials on the UICC during Emergency Calling in Limited Service Mode, as defined in the TS 23.401 [2], can not be successfully performed, the confidentiality protection of the RRC and NAS signaling, and user plane shall be omitted (see clause 15). This shall be accomplished by the network by selecting EEA0 for confidentiality protection of NAS, RRC and user plane.

User plane confidentiality protection shall be done at PDCP layer and is an operator option.

NOTE 2: User plane confidentiality protection is recommended to be used.

NOTE 3: Confidentiality protection for RRC and UP is applied at the PDCP layer, and no layers below PDCP are confidentiality protected. Confidentiality protection for NAS is provided by the NAS protocol.

5.1.3.2 Algorithm Identifier Values

All algorithms specified in this subclause are algorithms with a 128-bit input key except Null ciphering algorithm.

NOTE: Deviations from the above requirement have to be indicated explicitly in the algorithm identifier list below.

Each EPS Encryption Algorithm (EEA) will be assigned a 4-bit identifier. Currently, the following values have been defined for NAS, RRC and UP ciphering:

"00002"	EEA0 Nu	all ciphering algorithm
"00012"	128-EEA1	SNOW 3G based algorithm
"00102"	128-EEA2	AES based algorithm

The remaining values have been reserved for future use.

UEs and eNBs shall implement EEA0, 128-EEA1 and 128-EEA2 for both RRC signalling ciphering and UP ciphering.

UEs and MMEs shall implement EEA0, 128-EEA1 and 128-EEA2 for NAS signalling ciphering.

5.1.4 User data and signalling data integrity

5.1.4.1 Integrity requirements

Synchronization of the input parameters for integrity protection shall be ensured for the protocols involved in the integrity protection.

Integrity protection, and replay protection, shall be provided to NAS and RRC-signalling.

All NAS signaling messages except those explicitly listed in TS 24.301 [9] as exceptions shall be integrity-protected. All RRC signaling messages except those explicitly listed in TS 36.331 [21] as exceptions shall be integrity-protected.

When authentication of the credentials on the UICC during Emergency Calling in Limited Service Mode, as defined in the TS 23.401 [2], can not be successfully performed, the integrity and replay protection of the RRC and NAS signaling shall be omitted (see clause 15). This shall be accomplished by the network by selecting EIA0 for integrity protection of NAS and RRC. EIA0 shall only be used for unauthenticated emergency calls.

User plane packets between the eNB and the UE shall not be integrity protected.

5.1.4.2 Algorithm Identifier Values

All algorithms specified in this subclause are algorithms with a 128-bit input key.

NOTE: Deviations from the above requirement have to be indicated explicitly in the algorithm identifier list below.

Each EPS Integrity Algorithm (EIA) will be assigned a 4-bit identifier. Currently, the following values have been defined:

$"0000_{2}"$	EIA0	Null Integrity Protection algorithm
--------------	------	-------------------------------------

"00012"	128-EIA1	SNOW 3G
00012	120 21111	

"00102" 128-EIA2 AES

The remaining values have been reserved for future use.

UEs and eNBs shall implement 128-EIA1 and 128-EIA2 for RRC signalling integrity protection.

UEs and MMEs shall implement 128-EIA1 and 128-EIA2 for NAS signalling integrity protection.

UEs shall implement EIA0 for integrity protection of NAS and RRC signalling. As specified in clause 5.1.4.1 of this specification, EIA0 is only allowed for unauthenticated emergency calls.

Implementation of EIA0 in MMEs and eNBs is optional, EIA0, if implemented, shall be disabled in MMEs and eNBs in the deployments where support of unauthenticated emergency calling is not a regulatory requirement.

5.2 Security visibility and configurability

Although in general the security features should be transparent to the user, for certain events and according to the user's concern, greater user visibility of the operation of following security feature shall be provided:

 indication of access network encryption: the property that the user is informed whether the confidentiality of user data is protected on the radio access link, in particular when non-ciphered calls are set-up;

The ciphering indicator feature is specified in 3GPP TS 22.101 [23].

Configurability is the property that the user can configure whether the use or the provision of a service should depend on whether a security feature is in operation. A service can only be used if all security features, which are relevant to that service and which are required by the configurations of the user, are in operation. The following configurability features are suggested:

- enabling/disabling user-USIM authentication: the user should be able to control the operation of user-USIM authentication, e.g., for some events, services or use.

5.3 Security requirements on eNodeB

5.3.1 General

The security requirements given in this section apply to all types of eNodeBs. More stringent requirements for specific types of eNodeBs may be defined in other 3GPP specifications.

5.3.2 Requirements for eNB setup and configuration

Setting up and configuring eNBs shall be authenticated and authorized so that attackers shall not be able to modify the eNB settings and software configurations via local or remote access.

1. Security associations are required between the EPS core and the eNB and between adjacent eNBs, connected via X2. These security association establishments shall be mutually authenticated and used for communication between the entities. The security associations shall be realized according to clause 11 and 12 of this specification.

The decision on whether or not to use the certificate enrolment mechanism specified in TS 33.310 [6] for eNB is left to operators.

- 2. Communication between the remote/local O&M systems and the eNB shall be mutually authenticated.
- 3. The eNB shall be able to ensure that software/data change attempts are authorized
- 4. The eNB shall use authorized data/software.
- 5. Sensitive parts of the boot-up process shall be executed with the help of the secure environment.
- 6. Confidentiality of software transfer towards the eNB shall be ensured.
- 7. Integrity protection of software transfer towards the eNB shall be ensured.

5.3.3 Requirements for key management inside eNB

The EPS core network provides subscriber specific session keying material for the eNBs, which also hold long term keys used for authentication and security association setup purposes. Protecting all these keys is important.

1. Keys stored inside eNBs shall never leave a secure environment within the eNB except when done in accordance with this or other 3GPP specifications.

5.3.4 Requirements for handling User plane data for the eNB

It is eNB's task to cipher and decipher user plane packets between the Uu reference point and the S1/X2 reference points.

- 1. User plane data ciphering/deciphering shall take place inside the secure environment where the related keys are stored.
- 2. The transport of user data over S1-U and X2-U shall be integrity, confidentially and replay-protected from unauthorized parties. If this is to be accomplished by cryptographic means, clause 12 shall be applied.
- NOTE: The use of cryptographic protection on S1-U and X2-U is an operator's decision. In case the eNB has been placed in a physically secured environment then the 'secure environment' may include other nodes and links beside the eNB.

5.3.4a Requirements for handling Control plane data for the eNB

It is eNB's task to provide confidentiality and integrity protection for control plane packets on the S1/X2 reference points.

- 1. Control plane data ciphering/deciphering shall take place inside the secure environment where the related keys are stored.
- 2. The transport of control plane data over S1-MME and X2-C shall be applied to integrity-, confidentiality- and replay-protected from unauthorized parties. If this is to be accomplished by cryptographic means, clause 11 shall be applied.
- NOTE: The use of cryptographic protection on S1-MME and X2-C is an operator's decision. In case the eNB has been placed in a physically secured environment then the 'secure environment' may include other nodes and links beside the eNB.

5.3.5 Requirements for secure environment of the eNB

The secure environment is logically defined within the eNB and is a composition of functions for the support of sensitive operations.

- 1. The secure environment shall support secure storage of sensitive data, e.g. long term cryptographic secrets and vital configuration data.
- 2. The secure environment shall support the execution of sensitive functions, e.g. en-/decryption of user data and the basic steps within protocols which use long term secrets (e.g. in authentication protocols).
- 3. Sensitive data used within the secure environment shall not be exposed to external entities.
- 4. The secure environment shall support the execution of sensitive parts of the boot process.
- 5. The secure environment's integrity shall be assured.
- 6. Only authorised access shall be granted to the secure environment, i.e. to data stored and used within, and to functions executed within.

5.4 Void

6 Security Procedures between UE and EPC Network Elements

6.1 Authentication and key agreement

6.1.1 AKA procedure

NOTE 1: Authentication data in this subclause stands for EPS Authentication vector(s).

EPS AKA is the authentication and key agreement procedure that shall be used over E-UTRAN.

A Rel-99 or later USIM application on a UICC shall be sufficient for accessing E-UTRAN, provided the USIM application does not make use of the separation bit of the AMF in a way described in TS 33.102 [4] Annex F. Access to E-UTRAN with a 2G SIM or a SIM application on a UICC shall not be granted.

An ME that has E-UTRAN radio capability shall support the USIM-ME interface as specified in TS 31.102 [13]

EPS AKA shall produce keying material forming a basis for user plane (UP), RRC, and NAS ciphering keys as well as RRC and NAS integrity protection keys.

NOTE 2: Key derivation requirements of AS and NAS keys can be found in subclause 7.2.1.

The MME sends to the USIM via ME the random challenge RAND and an authentication token AUTN for network authentication from the selected authentication vector. It also includes a KSI_{ASME} for the ME which will be used to identify the K_{ASME} (and further keys derived from the K_{ASME}) that results from the EPS AKA procedure.

At receipt of this message, the USIM shall verify the freshness of the authentication vector by checking whether AUTN can be accepted as described in TS 33.102[4]. If so, the USIM computes a response RES. USIM shall compute CK and IK which are sent to the ME. If the USIM computes a Kc (i.e. GPRS Kc) from CK and IK using conversion function c3 as described in TS 33.102 [4], and sends it to the ME, then the ME shall ignore such GPRS Kc and not store the GPRS Kc on USIM or in ME. If the verification fails, the USIM indicates to the ME the reason for failure and in the case of a synchronisation failure passes the AUTS parameter (see TS 33.102 [4]).

An ME accessing E-UTRAN shall check during authentication that the "separation bit" in the AMF field of AUTN is set to 1. The "separation bit" is bit 0 of the AMF field of AUTN.

- NOTE 3: This separation bit in the AMF can not be used anymore for operator specific purposes as described by TS 33.102 [4], Annex F.
- NOTE 4: If the keys CK, IK resulting from an EPS AKA run were stored in the fields already available on the USIM for storing keys CK and IK this could lead to overwriting keys resulting from an earlier run of UMTS AKA. This would lead to problems when EPS security context and UMTS security context were held simultaneously (as is the case when security context is stored e.g. for the purposes of Idle Mode Signaling Reduction). Therefore, "plastic roaming" where a UICC is inserted into another ME will necessitate an EPS AKA authentication run if the USIM does not support EMM parameters storage.

UE shall respond with User authentication response message including RES in case of successful AUTN verification and successful AMF verification as described above. In this case the ME shall compute K_{ASME} from CK, IK, and serving network's identity (SN id) using the KDF as specified in Annex A. SN id binding implicitly authenticates the serving network's identity when the derived keys from K_{ASME} are successfully used.

NOTE 5: This does not preclude a USIM (see TS 31.102 [13]) in later releases having the capability of deriving K_{ASME}.

Otherwise UE shall send an authentication failure message with a CAUSE value indicating the reason for failure. In case of a synchronisation failure of AUTN (as described in TS 33.102 [4]), the UE also includes AUTS that was provided by the USIM. Upon receipt of an authentication failure message, the MME may initiate further identity requests and authentications towards the UE. (see TS 24.301 [9]).

The MME checks that the RES equals XRES. If so the authentication is successful. If not, depending on type of identity used by the UE in the initial NAS message, the MME may initiate further identity requests or send an authentication reject message towards the UE (see TS 24.301 [9]).

Figure 6.1.1-1 describes EPS AKA procedure, which is based on UMTS AKA (see TS 33.102[4]). The following keys are shared between UE and HSS:

- **K** is the permanent key stored on the USIM on a UICC and in the Authentication Centre AuC.
- **CK, IK** is the pair of keys derived in the AuC and on the USIM during an AKA run. CK, IK shall be handled differently depending on whether they are used in an EPS security context or a legacy security context, as described in subclause 6.1.2.

As a result of the authentication and key agreement, an intermediate key K_{ASME} shall be shared between UE and MME i.e. the ASME for EPS.

Figure 6.1.1-1: Successful EPS AKA authentication

6.1.2 Distribution of authentication data from HSS to serving network

NOTE 1: Authentication data in this subclause stands for EPS Authentication vector(s).

The purpose of this procedure is to provide the MME with one or more EPS authentication vectors (RAND, AUTN, XRES, K_{ASME}) from the user's HE (HSS) to perform user authentication. Each EPS authentication vector can be used to authenticate the UE.

NOTE 2: It is recommended that the MME fetch only one EPS authentication vector at a time as the need to perform AKA runs has been reduced in EPS through the use of a more elaborate key hierarchy. In particular, service requests can be authenticated using a stored K_{ASME} without the need to perform AKA. Furthermore, the sequence number management schemes in TS 33.102, Annex C [4], designed to avoid re-synchronisation problems caused by interleaving use of batches of authentication vectors, are only optional. Re-synchronisation problems in EPS can be avoided, independently of the sequence number management scheme, by immediately using an authentication vector retrieved from the HSS in an authentication procedure between UE and MME.

MME		HE
	Authentication data request IMSI, SN identity, Network Type	→
4	Authentication data response EPS-Authentication Vector (s)	

An EPS authentication vector is derived from the authentication vector defined in TS 33.102 [4] clause 6.3.2. To derive the key K_{ASME} in the HE, the KDF as specified in Annex A is used which shall contain following mandatory input parameters: CK, IK and SN identity.

If the Network Type equals E-UTRAN then the "separation bit" in the AMF field of AUTN shall be set to 1 to indicate to the UE that the authentication vector is only usable for AKA in an EPS context, if the "separation bit" is set to 0, the vector is usable in a non-EPS context only (e.g. GSM, UMTS). For authentication vectors with the "separation bit" set to 1, the secret keys CK and IK generated during AKA shall never leave the HSS.

The MME invokes the procedures by requesting authentication vectors from the HE (Home environment).

The *authentication data request* shall include the IMSI, the Serving Network identity i.e. MCC + MNC, and the Network Type (i.e. E-UTRAN). In the case of a synchronisation failure, the MME shall also include RAND and AUTS. In this case the HE checks the AUTS parameter before sending new authentication vectors to the MME (see TS 33.102 [4]).

Upon the receipt of the *authentication data request* from the MME, the HE may have pre-computed the required number of EPS authentication vectors and retrieve them from the HSS database or may compute them on demand.

NOTE 3: For K_{ASME} the possibilities for pre-computation are restricted due to the PLMN-binding.

NOTE 4: The HSS needs to ensure that the MME requesting the authentication data is entitled to use the SN id used to calculate K_{ASME}. The exact details of how to achieve this are not covered in this specification.

The HE sends an authentication response back to the MME that contains the requested information. If multiple EPS authentication vectors had been requested then they are ordered based on their sequence numbers. The MME shall be aware of the order of the EPS authentication vectors and shall use that the EPS authentication vectors in order.

6.1.3 User identification by a permanent identity

The user identification mechanism should be invoked by the serving network whenever the user cannot be identified by means of a temporary identity (GUTI). In particular, it should be used when the serving network cannot retrieve the IMSI based on the GUTI by which the user identifies itself on the radio path.

The mechanism described in figure 6.1.3-1 allows the identification of a user on the radio path by means of the permanent subscriber identity (IMSI).

ME/USIM	MME
Identity Requ	lest
Identity Response	(IMSI)

Figure 6.1.3-1: User identity query

The mechanism is initiated by the MME that requests the user to send its permanent identity. The user's response contains the IMSI in cleartext. This represents a breach in the provision of user identity confidentiality.

6.1.4 Distribution of IMSI and authentication data within one serving network domain

NOTE 1: Authentication data in this subclause stands for EPS security contexts and EPS authentication vector(s).

The purpose of this procedure is to provide a newly visited MME with authentication data from a previously visited MME within the same serving network domain.

NOTE 2: The following procedure in this clause is based on TAU procedure and it can also be applied for Attach procedure where all the corresponding texts for 'TAU' in the following procedure should be replaced with 'Attach'.

The procedure is shown in Figure 6.1.4-1

Figure 6.1.4-1: Distribution of IMSI and authentication data within one serving domain

The procedure shall be invoked by the newly visited MMEn after the receipt of a Tracking Area update request from the user wherein the user is identified by means of a temporary user identity GUTIo and the Tracking area identity TAIo under the jurisdiction of a previously visited MMEo that belongs to the same serving network domain as the newly visited MMEn.

The protocol steps are as follows:

- a) The MMEn sends a message to the MMEo, this message contains GUTIo and the received TAU message.
- b) The MMEo searches the user data in the database and checks the integrity protection on the TAU message.

If the user is found and the integrity check succeeds, the MMEo shall send a response back that:

- i) shall include the IMSI,
- ii) may include a number of unused EPS-authentication vectors ordered on a first-in / first-out basis, and
- iii) may include any EPS security contexts it holds

The MMEo subsequently deletes the EPS-authentication vectors and any EPS security contexts which have been sent.

If the user cannot be identified or the integrity check fails, then the MMEo shall send a response indicating that the user identity cannot be retrieved.

c) If the MMEn receives a response with an IMSI, it creates an entry and stores any EPS-authentication vectors and any EPS security context that may be included.

If the MMEn receives a response indicating that the user could not be identified, it shall initiate the user identification procedure described in clause 6.1.3 during the Initial E-UTRAN Attach procedure, or it shall reject the TAU Request message initiated by UE during the TAU procedure (see clause 4.4.4.3 in TS24.301[9]).

The same procedure does not apply to distribution of EPS authentication data between MME and SGSN in the same serving network domain, i.e. EPS authentication data shall not be forwarded from an MME towards an SGSN.

NOTE 3: This is due to the fact that EPS authentication data does not contain CK and IK and, hence, is not useful for the SGSN.

6.1.5 Distribution of IMSI and authentication data between different serving network domains

NOTE 1: Authentication data in this subclause stands for EPS security contexts and EPS authentication vector(s).

In general, the distribution of IMSI and authentication data between MMEs belonging to different serving network domains of shall be performed as described for the distribution of IMSI and authentication data within the same service network domain in subclause 6.1.4. In particular, the current EPS security context data may be transferred between MMEs belonging to different serving network domains. However, there is the following restriction:

- Unused EPS authentication vectors, or non-current EPS security contexts, shall not be distributed between MMEs belonging to different serving domains (PLMNs).

The same procedure does not apply to distribution of EPS authentication data between MME and SGSN in different serving network domains, i.e. EPS authentication data shall not be forwarded from an MME towards an SGSN.

NOTE 2: This is due to the fact that EPS authentication data does not contain CK and IK and, hence, is not useful for the SGSN.

6.1.6 Distribution of IMSI and UMTS authentication vectors between MMEs or between MME and SGSN

This subclause applies to both distribution of UMTS authentication vectors within one serving network domain and distribution of UMTS authentication vectors between different serving network domains. The following rules apply to the distribution of UMTS authentication vectors between two MMEs, and between an SGSN and an MME:

a) MME to MME

UMTS authentication vectors that were previously received from an SGSN shall not be forwarded between MME's.

b) SGSN to MME

An SGSN may forward unused UMTS authentication vectors to an MME. only if MME and SGSN are in the same serving network domain.

c) MME to SGSN

UMTS AVs which were previously stored in the MME may be forwarded back towards the same SGSN.

UMTS AVs which were previously stored in the MME shall not be forwarded towards other SGSNs.

6.2 EPS key hierarchy

Requirements on EPC and E-UTRAN related to keys:

- a) The EPC and E-UTRAN shall allow for use of encryption and integrity protection algorithms for AS and NAS protection having keys of length 128 bits and for future use the network interfaces shall be prepared to support 256 bit keys.
- b) The keys used for UP, NAS and AS protection shall be dependent on the algorithm with which they are used.

Figure 6.2-1: Key hierarchy in E-UTRAN

The key hierarchy (see Figure 6.2-1) includes following keys: KeNB, KNASint, KNASenc, KUPenc, KRRCint and KRRCenc

• \mathbf{K}_{eNB} is a key derived by ME and MME from \mathbf{K}_{ASME} or by ME and target eNB.

Keys for NAS traffic:

- $\mathbf{K}_{\text{NASint}}$ is a key, which shall only be used for the protection of NAS traffic with a particular integrity algorithm This key is derived by ME and MME from \mathbf{K}_{ASME} , as well as an identifier for the integrity algorithm using the KDF as specified in Annex A.
- $\mathbf{K}_{\mathbf{NASenc}}$ is a key, which shall only be used for the protection of NAS traffic with a particular encryption algorithm. This key is derived by ME and MME from $\mathbf{K}_{\mathrm{ASME}}$, as well as an identifier for the encryption algorithm using the KDF as specified in Annex A.

Keys for UP traffic:

• **K**_{UPenc} is a key, which shall only be used for the protection of UP traffic with a particular encryption algorithm. This key is derived by ME and eNB from K_{eNB}, as well as an identifier for the encryption algorithm using the KDF as specified in Annex A.

Keys for RRC traffic:

- **K**_{**RRCint**} is a key, which shall only be used for the protection of **RRC** traffic with a particular integrity algorithm. K_{**RRCint**} is derived by ME and eNB from K_{eNB}, as well as an identifier for the integrity algorithm using the KDF as specified in Annex A.
- $\mathbf{K}_{\mathbf{RRCenc}}$ is a key, which shall only be used for the protection of RRC traffic with a particular encryption algorithm. $\mathbf{K}_{\mathbf{RRCenc}}$ is derived by ME and eNB from \mathbf{K}_{eNB} as well as an identifier for the encryption algorithm using the KDF as specified in Annex A.

Intermediate keys:

- **NH** is a key derived by ME and MME to provide forward security as described in clause 7.2.8.

- K_{eNB}^* is a key derived by ME and eNB when performing an horizontal or vertical key derivation as specified in clause 7.2.8 using a KDF as specified in Annex A.

Figure 6.2-2 shows the dependencies between the different keys, and how they are derived from the network nodes point of view. Figure 6.2-3 shows the corresponding relations and derivations as performed in the ME. Two dashed inputs to a KDF means one of the inputs is used depending on the circumstances of the key derivation.

NOTE: Figures 6.2-2 and 6.2-3 do not cover the derivations at IRAT mobility (see clauses 9 and 10).

Figure 6.2-2: Key distribution and key derivation scheme for EPS (in particular E-UTRAN) for network nodes.

Figure 6.2-3: Key derivation scheme for EPS (in particular E-UTRAN) for the ME.

As the figures 6.2-2 and 6.2-3 show, the length of K_{ASME} , K_{eNB} and NH is 256 bits, 256-bit NAS, UP and RRC keys are always derived from K_{ASME} and K_{eNB} respectively. In case the encryption or integrity algorithm used to protect NAS, UP or RRC requires a 128-bit key as input, the key is truncated and the 128 least significant bits are used. Figures 6.2-2 and 6.2-3 illustrate the truncation to 128 bits keys.

The function Trunc takes as input a 256-bit string, and returns a truncated output as defined in Annex A.7.

6.3 EPS key identification

The key K_{ASME} shall be identified by the key set identifier eKSI. eKSI may be either of type KSI_{ASME} or of type KSI_{SGSN} . An eKSI shall be stored in the UE and the MME together with K_{ASME} and the temporary identifier GUTI, if available.

NOTE 1: The GUTI points to the MME where the K_{ASME} is stored.

The key set identifier KSI_{ASME} is a parameter which is associated with the K_{ASME} derived during EPS AKA authentication. The key set identifier KSI_{ASME} is allocated by the MME and sent with the authentication request message to the mobile station where it is stored together with the K_{ASME} . The purpose of the KSI_{ASME} is to make it possible for the UE and the MME to identify a native K_{ASME} without invoking the authentication procedure. This is used to allow re-use of the K_{ASME} during subsequent connection set-ups.

The key set identifier KSI_{SGSN} is a parameter which is associated with the mapped K_{ASME} derived from UMTS keys during inter-RAT mobility, cf. clauses 9 and 10 of the present specification. The key set identifier KSI_{SGSN} is generated in both the UE and the MME respectively when deriving the mapped K_{ASME} during idle procedures in E-UTRAN and during handover from GERAN/UTRAN to E-UTRAN. The KSI_{SGSN} is stored together with the mapped K_{ASME} .

The purpose of the KSI_{SGSN} is to make it possible for the UE and the MME to indicate the use of the mapped K_{ASME} in inter-RAT mobility procedures (for details cf. clauses 9 and 10).

The format of eKSI shall allow a recipient of such a parameter to distinguish whether the parameter is of type 'KSI_{ASME}' or of type 'KSI_{SGSN}'. The format shall further contain a value field. KSI_{ASME} and KSI_{SGSN} have the same format. The value fields of KSI_{ASME} and KSI_{SGSN} are three bits each. Seven values are used to identify the key set. A value of '111' is used by the UE to indicate that a valid K_{ASME} is not available for use. Format of eKSI is described in [9].

The value '111' in the other direction from network to mobile station is reserved.

NOTE 2: In addition to EPS security contexts, the UE may also cache UMTS security contexts. These UMTS security contexts are identified by the KSI, as defined in TS 33.102 [4].

6.4 Handling of EPS security contexts

Any EPS security context shall be deleted from the ME if:

- a) the UICC is removed from the ME when the ME is in power on state;
- b) the ME is powered up and the ME discovers that a UICC different from the one which was used to create the EPS security context has been inserted to the ME;
- c) the ME is powered up and the ME discovers that no UICC has been inserted to the ME.

K_{ASME} shall never be transferred from the EPC to an entity outside the EPC.

Both the ME and MME shall be capable of storing one non-current EPS security context and one current EPS security context in volatile memory. In addition, while connected to E-UTRAN the ME and MME shall be capable of storing in volatile memory the NCC, NH and the related K_{ASME} used to compute keying material for the current EPS AS security context.

Any successful run of an EPS AKA creates, by the definition in clause 3, a partial native EPS security context. This context shall overwrite any existing non-current EPS security context.

UE shall use its current EPS security context to protect the TAU Request or Attach Request. However, there may be cases in which this EPS security context is not the current one in the MME. In such cases, if the MME receives a TAU Request or Attach Request protected with a non-current full EPS security context, then this context becomes the current EPS security context and the MME shall delete any existing current EPS security context.

After a successful run of a NAS SMC relating to the eKSI associated with an EPS security context, this context becomes the current EPS security context and shall overwrite any existing current EPS security context.

NOTE 1: The ME ensures that, whenever the native EPS NAS security context stored on the USIM (if supported by USIM) or in non-volatile memory of the ME is marked as valid during the process of changing state to EMM-DEREGISTERED, it is consistent with the security context stored in the volatile memory of the ME. This is described in clause 7.2.5.

The rules for handling security contexts after a handover to E-UTRAN are given in clause 9.2.2.1.

The full native EPS NAS security context (except for K_{NASenc} and K_{NASint}) shall be stored on the USIM (if the USIM supports EMM parameters storage) or in the non-volatile memory of the ME (if the USIM does not support EMM parameters storage) only during the process of transitioning to EMM-DEREGISTERED state or when an attempt to transition away from EMM-DEREGISTERED state fails, as described in clause 7.2.5. The ME shall under no other circumstances store the EPS NAS security context parameters on the USIM or non-volatile ME memory.

NOTE 2: Only native EPS NAS security context is stored in the EMM parameters file on the USIM or in nonvolatile ME memory. A mapped EPS NAS security context is never stored in these two places.

6.5 Handling of NAS COUNTs

Each separate K_{ASME} has a distinct pair of NAS COUNTs associated with it. It is essential that the NAS COUNTs for a particular K_{ASME} are not reset to the start values (that is the NAS COUNTs only have their start value when a new

 K_{ASME} is created). This prevents the security issue of using the same NAS COUNTs with the same NAS keys, e.g. key stream re-use, in the case a UE moves back and forth between two MMEs and the same NAS keys are re-derived.

The NAS COUNTs shall only be set to the start value in the following cases:

- for a partial native EPS NAS security context created by a successful AKA run,
- NOTE: The NAS COUNTs are not actually needed at the UE for a native context until it has successfully received the first NAS Security Mode Command for that security context. The NAS COUNTs are not needed at the MME until it sends the first NAS Security Mode Command for that security context. Before the MME sends the first NAS Security Mode Command for a given partial native security context, the MME sets the NAS COUNTs for the security context to 0. After the NAS SMC message is sent for that partial native security context the NAS COUNTs for that partial native context are increased for each following sent NAS message as specified in TS 24.301.
- or for an EPS NAS security context created through a context mapping during a handover from UTRAN/GERAN to E-UTRAN,
- or for an EPS NAS security context created through a context mapping during idle mode mobility from UTRAN/GERAN to E-UTRAN.

The NAS COUNTs shall not be reset during idle mode mobility or handover for an already existing native EPS NAS security context.

The start value of NAS COUNT shall be zero (0).

7 Security Procedures between UE and EPS Access Network Elements

7.1 Mechanism for user identity confidentiality

The MME shall allocate a GUTI to a UE in order to support the subscriber identity confidentiality. The GUTI is defined in TS 23.003 [3].

S-TMSI, the shortened form of the GUTI, is used to support the subscriber identity confidentiality with more efficient radio signalling procedures (e.g. paging and Service Request). A new GUTI shall be sent to the UE only after a successful activation of NAS security.

7.2 Handling of user-related keys in E-UTRAN

7.2.1 E-UTRAN key setting during AKA

Authentication and key setting are triggered by the authentication procedure. Authentication and key setting may be initiated by the network as often as the network operator wishes. Key setting can occur as soon as the identity of the mobile subscriber (i.e. GUTI or IMSI) is known by the MME. A successful run of AKA results in a new K_{ASME} that is stored in the UE and MME.

NAS keys, K_{eNB} and the RRC and UP keys are derived from K_{ASME} using the KDFs specified in Annex A.

The NAS keys derived from the new K_{ASME} are taken in use in the MME and the UE by means of the NAS security mode set-up procedure (see subclause 7.2.4.4). The AS keys are taken into use with the AS security mode set-up procedure (see subclause 7.2.4.5) or with the key change on the fly procedure (see subclause 7.2.9.2).

7.2.2 E-UTRAN key identification

Clause 6.3 of this specification states how the key K_{ASME} is identified, namely by the key set identifier eKSI. Keys K_{NASenc} and K_{NASint} in the E-UTRAN key hierarchy specified in clause 6.2, which are derived from K_{ASME} , can be uniquely identified by eKSI together with those parameters from the set {algorithm distinguisher, algorithm identifier}, which are used to derive these keys from K_{ASME} according to Annex A.

The initial K_{eNB} can be uniquely determined by the key set identifier, i.e. eKSI, together with the uplink NAS COUNT are used to derive it. The intermediate key NH as defined in clause 7 can be uniquely determined by the key set identifier, i.e. eKSI, together with the initial K_{eNB} derived from the current NAS security context for use during the ongoing CONNECTED state and a counter counting how many NH-derivations have already been performed from this initial K_{eNB} .according to Annex A.4. The next hop chaining count, NCC, represents the 3 least significant bits of this counter.

Intermediate key K_{eNB}^* , defined in clause 7, as well as keys non-initial K_{eNB} , K_{RRCint} , K_{RRCenc} , and K_{UPenc} in the E-UTRAN key hierarchy specified in clause 6.2 can be uniquely identified by eKSI together with those parameters from the set {Initial K_{eNB} or NH, algorithm distinguisher, algorithm identifier, and sequence of PCIs and EARFCN-DLs used in horizontal key derivations from the initial K_{eNB} or NH}, which are used to derive these keys from K_{ASME} according to clause 7 and Annex A.

It is specified in the remainder of clause 7, as well as in clause 9 and 10, which of the above parameters need to be included in a security-relevant message to allow the entity receiving the message to uniquely identify a certain key.

7.2.3 E-UTRAN key lifetimes

All E-UTRAN keys are derived based on a K_{ASME} . The key hierarchy which is described in clause 6.2 does not allow direct update to RRC and UP keys, but fresh RRC and UP keys are derived based on a fresh K_{eNB} , which is bound to certain dynamic parameters (like PCI) or fresh key derivation parameter(s) in state transitions (like NAS uplink COUNT). This results as fresh RRC and UP keys in the eNB between inter-eNB handovers and state transitions (see

subclauses 7.2.6 to 7.2.8). The handling (creation, modification and update) of the E-UTRAN keys in the various state transitions is described in clauses 7.2.5, 7.2.6, 7.2.7 and 7.2.8.

 K_{ASME} shall be created only by running a successful AKA or by the inter-RAT procedures towards E-UTRAN (cf clauses 9 and 10). In case the UE does not have a valid K_{ASME} , a KSI_{ASME} with value "111" shall be sent by the UE to the network, which can initiate (re-)authentication procedure to get a new K_{ASME} based on a successful AKA authentication.

7.2.4 Security mode command procedure and algorithm negotiation

7.2.4.1 Requirements for algorithm selection

- a) An active UE and a serving network shall agree upon algorithms for
 - RRC ciphering and RRC integrity protection (to be used between UE and eNB)
 - UP ciphering (to be used between UE and eNB)
 - NAS ciphering and NAS integrity protection (to be used between UE and MME)
- b) The serving network shall select the algorithms to use dependent on
 - the UE security capabilities of the UE,
 - the configured allowed list of security capabilities of the currently serving network entity
- c) The same set of ciphering and integrity algorithms shall be supported by the UE both for AS and NAS level.
- d) Each selected algorithm shall be acknowledged to the UE in an integrity protected way such that the UE is ensured that the algorithm selection was not manipulated, i.e. that the UE security capabilities were not bidden down.
- e) The UE security capabilities the ME sent to the network shall be repeated in an integrity protected NAS level message to the ME such that "bidding down attacks" against the UE's security capabilities can be detected by the ME. The UE security capabilities apply to both AS and NAS level security.
- f) Separate AS and NAS level security mode command procedures are required. AS level security mode command procedure configures AS security (RRC and UP) and NAS level security mode command procedure configures NAS security.
 - a. Both integrity protection and ciphering for RRC are activated within the same AS SMC procedure, but not necessarily within the same message.
 - b. User plane ciphering is activated at the same time as RRC ciphering.
- g) It shall be possible that the selected AS and NAS algorithms are different at a given point of time.

7.2.4.2 Procedures for AS algorithm selection

7.2.4.2.1 Initial AS security context establishment

Each eNB shall be configured via network management with lists of algorithms which are allowed for usage. There shall be one list for integrity algorithms, and one for ciphering algorithms. These lists shall be ordered according to a priority decided by the operator. When AS security context is established in the eNB, the MME shall send the UE EPS security capabilities to the eNB. The eNB shall choose the ciphering algorithm which has the highest priority from its configured list and is also present in the UE EPS security capabilities. The eNB shall choose the integrity algorithm which has the highest priority from its configured list and is also present in the UE EPS security capabilities. The eNB shall choose the integrity algorithm which has the highest priority from its configured list and is also present in the UE EPS security capabilities. The chosen algorithms shall be indicated to the UE in the AS SMC. The ciphering algorithm is used for ciphering of the user plane and RRC traffic. The integrity algorithm is used for integrity protection of the RRC traffic.

7.2.4.2.2 X2-handover

At handover from a source eNB over X2 to a target eNB, the source eNB shall include the UE EPS security capabilities and ciphering and integrity algorithms used in the source cell in the handover request message. The target eNB shall select the algorithm with highest priority from the UE EPS security capabilities according to the prioritized locally configured list of algorithms (this applies for both integrity and ciphering algorithms). The chosen algorithms shall be indicated to the UE in the handover command if the target eNB selects different algorithms compared to the source eNB. If the UE does not receive any selection of integrity and ciphering algorithms it continues to use the same algorithms as before the handover (see TS 36.331 [21]). In the path-switch message, the target eNB shall send the UE EPS security capabilities received from the source eNB to the MME. The MME shall verify that the UE EPS security capabilities received from the eNB are the same as the UE EPS security capabilities that the MME has stored. If there is a mismatch, the MME may log the event and may take additional measures, such as raising an alarm.

NOTE: Transferring the ciphering and integrity algorithms used in the source cell to the target eNB in the handover request message is for the target eNB to decipher and integrity verify the RRCReestablishmentComplete message on SRB1 in the potential RRCConnectionRe-establishment procedure. The information is also used by the target eNB to decide if it is necessary to include a new selection of security algorithms in the handover command.

7.2.4.2.3 S1-handover

At handover from a source eNB to a target eNB over S1 (possibly including an MME change and hence a transfer of the UE security capabilities from source MME to target MME), the target MME shall send the UE EPS security capabilities to the target eNB in the S1 AP HANDOVER REQUEST message. The target eNB shall select the algorithm with highest priority from the UE EPS security capabilities according to the prioritized locally configured list of algorithms (this applies for both integrity and ciphering algorithms). The chosen algorithms shall be indicated to the UE in the handover command if the target eNB selects different algorithms compared to the source eNB. If the UE does not receive any selection of integrity and ciphering algorithms it continues to use the same algorithms as before the handover (see TS 36.331 [21]).

7.2.4.2.4 Intra-eNB handover

It is not required to change the AS security algorithm during intra-eNB handover. If the UE does not receive any selection of new AS security algorithms during an intra-eNB handover, the UE continues to use the same algorithms as before the handover (see TS 36.331 [21]).

7.2.4.3 Procedures for NAS algorithm selection

7.2.4.3.1 Initial NAS security context establishment

Each MME shall be configured via network management with lists of algorithms which are allowed for usage. There shall be one list for NAS integrity algorithms, and one for NAS ciphering algorithms. These lists shall be ordered according to a priority decided by the operator.

To establish the NAS security context, the MME shall choose one NAS ciphering algorithm and one NAS integrity protection algorithm. The MME shall then initiate a NAS security mode command procedure, and include the chosen algorithms and UE security capabilities (to detect modification of the UE security capabilities by an attacker) in the message to the UE (see clause 7.2.4.4). The MME shall select the NAS algorithms which have the highest priority according to the ordered lists.

7.2.4.3.2 MME change

In case there is change of MMEs and algorithms to be used for NAS, the target MME shall initiate a NAS security mode command procedure and include the chosen algorithms and the UE security capabilities (to detect modification of the UE security capabilities by an attacker) in the message to the UE (see clause 7.2.4.4). The MME shall select the NAS algorithms which have the highest priority according to the ordered lists (see 7.2.4.3.1).

NOTE: After an S1-handover with MME change a TAU procedure is executed. The same is true for an inter-RAT handover to E-UTRAN and for both inter- and intra-RAT idle mode mobility resulting in a change of MMEs.

7.2.4.4 NAS security mode command procedure

The NAS SMC procedure consists of a roundtrip of messages between MME and UE. The MME sends the NAS security mode command to the UE and the UE replies with the NAS security mode complete message.

The NAS security mode command message from MME to UE shall contain the replayed UE security capabilities, the selected NAS algorithms, the eKSI for identifying K_{ASME} , and both $NONE_{UE}$ and $NONCE_{MME}$ in the case of creating a mapped context in idle mobility (see clause 9.1.2). This message shall be integrity protected (but not ciphered) with NAS integrity key based on K_{ASME} indicated by the eKSI in the message (see figure 7.2.4.4-1).

The UE shall verify the integrity of the NAS security mode command message. This includes ensuring that the UE security capabilities sent by the MME match the ones stored in the UE to ensure that these were not modified by an attacker and checking the integrity protection using the indicated NAS integrity algorithm and the NAS integrity key based on K_{ASME} indicated by the eKSI. In addition, when creating a mapped context for the case described in clause 9.1.2, the UE shall ensure the received NONCE_{UE} is the same as the NONCE_{UE} sent in the TAU Request and also calculate K'_{ASME} from CK, IK and the two nonces (see Annex A.11).

If the MME receives no response to a NAS Security Mode Command that included nonces to create a mapped context and it wishes to try again to create the mapped context, the MME shall use the same values of $NONCE_{UE}$ and $NONCE_{MME}$.

If the UE receives a re-transmitted NAS Security Mode Command, i.e one containing the nonces, after it has successfully received a previous one (and hence created a mapped EPS NAS security context), the UE shall process the message as above, except that it is not required to re-generate the K'_{ASME} or check the NONCE _{UE} if it does not re-generate the K'_{ASME} .

If the checks of the NAS Security Mode Command pass the UE shall respond with a NAS Security Mode Complete.

The UE shall delete NONCE UE once the TAU procedure is complete.

If successfully verified, the UE shall start NAS integrity protection and ciphering/deciphering with this security context and sends the NAS security mode complete message to MME ciphered and integrity protected The NAS security mode complete message shall include IMEISV in case MME requested it in the NAS SMC Command message.

The MME shall de-cipher and check the integrity protection on the NAS Security Mode Complete using the keys and algorithms indicated in the NAS Security Mode Command. NAS downlink ciphering at the MME with this security context shall start after receiving the NAS security mode complete message. NAS uplink deciphering at the MME with this context starts after sending the NAS security mode command message.

If any verification of the NAS security mode command is not successful in the ME, the ME shall reply with a NAS security mode reject message (see TS 24.301 [9]). The NAS security mode reject message and all following NAS messages shall be protected with the EPS NAS security context, i.e., the EPS NAS security context used prior to the NAS security mode command that failed (until a new EPS NAS security context is established, e.g., via a new NAS security mode command procedure). If no EPS NAS security context existed prior to the NAS security mode command, the NAS security mode reject message cannot be protected.

NOTE: If the uplink NAS COUNT will wrap around by sending the security mode reject message, the UE releases the NAS connection as specified in TS 24.301 [9] instead of sending the security mode reject message.

Figure 7.2.4.4-1: NAS security mode command procedure

7.2.4.5 AS security mode command procedure

The AS SMC procedure consists of a roundtrip of messages between eNB and UE. The eNB sends the AS security mode command to the UE and the UE replies with the AS security mode complete message. See figure 7.2.4.5-1.

The AS security mode command message from eNB to UE shall contain the selected AS algorithms. This message shall be integrity protected with RRC integrity key based on the current K_{ASME}.

The AS security mode complete message from UE to eNB shall be integrity protected with the selected RRC algorithm indicated in the AS security mode command message and RRC integrity key based on the current KASME.

RRC and UP downlink ciphering (encryption) at the eNB shall start after sending the AS security mode command message. RRC and UP uplink deciphering (decryption) at the eNB shall start after receiving and successful verification of the AS security mode complete message.

RRC and UP uplink ciphering (encryption) at the UE shall start after sending the AS security mode complete message. RRC and UP downlink deciphering (decryption) at the UE shall start after receiving and successful verification of the AS security mode command message

If any control of the AS security mode command is not successful in the ME, the ME shall reply with an unprotected security mode failure message (see TS 36.331[21]).

AS security mode command always changes the AS keys.

7.2.4a Algorithm negotiation for unauthenticated UEs in LSM

UEs that are in limited service mode (LSM) and that cannot be authenticated by the MME (for whatever reason) may still be allowed to establish emergency calls by sending the emergency attach request message. It shall be possible to configure whether the MME allows unauthenticated UEs in LSM to establish bearers for emergency calls or not. If an MME allows unauthenticated UEs in LSM to establish bearers for an emergency call, the MME shall for the NAS protocol use EIA0 and EEA0 as the integrity and ciphering algorithm respectively.

If the MME allows an unauthenticated UE in LSM to establish bearers for emergency calls after it has received the emergency attach request message from the UE, the MME shall:

- Select EIA0 and EEA0 as the NAS algorithms and signal this to the UE via the NAS security mode command procedure when activating the EPS NAS security context.
- Set the UE EPS security capabilities to only contain EIA0 and EEA0 when sending these to the eNB in the following messages:
 - S1 UE INITIAL CONTEXT SETUP
 - S1 UE CONTEXT MODIFICATION REQUEST
 - S1 HANDOVER REQUEST
- NOTE 1: As a result of that the MME only sends a UE EPS security capability containing EIA0 and EEA0 to the eNB when selecting EIA0 for NAS integrity protection is that the eNB is only capable of selecting EIA0 for AS integrity protection and EEA0 for AS confidentiality protection. That is, if EIA0 is used for NAS integrity protection, then EIA0 will always be used for AS integrity protection.

The rules for when the MME shall select EIA0 for NAS integrity protection, and when the UE shall accept a NAS security mode command selecting EIA0 for NAS integrity protection depends on whether the UE and MME can be certain that no EPS NAS security context can be established. The rules for determining this is defined in clause 15 of this specification. If the MME has selected EIA0 as the NAS integrity protection algorithm, the UE shall accept selection of EIA0 as the AS integrity protection algorithm. Selection of AS integrity protection algorithm happens via the AS security mode command procedure or via a handover command. The UE shall under no other circumstances accept selection of EIA0 as the AS integrity protection algorithm.

NOTE 2: A Rel-8 eNB that is the target eNB of a handover, where EIA0 is the only integrity protection algorithm in the UE's EPS security capabilities, rejects the handover since the eNB does not support EIA0.

7.2.5 Key handling at state transitions to and away from EMM-DEREGISTERED

7.2.5.1 Transition to EMM-DEREGISTERED

There are different reasons for transition to the EMM-DEREGISTERED state. If a NAS messages leads to state transition to EMM-DEREGISTERED, it shall be security protected by the current EPS NAS security context (mapped or native), if such exists in the UE or MME.

NOTE: The present specification only considers the states EMM-DEREGISTERED and EMM-REGISTERED and transitions between these two states. Other specifications define additional EMM states (see, e.g., TS 24.301 [9]).

On transitioning to EMM-DEREGISTERED, the UE and MME shall do the following:

- 1. If they have a full non-current native EPS NAS security context and a current mapped EPS NAS security context, then they shall make the non-current native EPS NAS security context the current one.
- 2. They shall delete any mapped or partial EPS NAS security contexts they hold.

Handling of the remaining authentication data for each of these cases are given below:

- 1. Attach reject: All authentication data shall be removed from the UE and MME
- 2. Detach:

- a. UE-initiated
 - i. If the reason is switch off then all the remaining authentication data shall be removed from the UE and MME with the exception of:
 - the current native EPS NAS security context (as in clause 6.1.1), which should remain stored in the MME and UE, and
 - any unused authentication vectors, which may remain stored in the MME.
 - ii. If the reason is not switch off then MME and UE shall keep all the remaining authentication data.
- b. MME-initiated
 - i. Explicit: all the remaining authentication data shall be kept in the UE and MME if the detach type is reattach.
 - ii. Implicit: all the remaining authentication data shall be kept in the UE and MME.
- c. HSS-initiated: If the message is "subscription withdrawn" then all the remaining authentication data shall be removed from the UE and MME.
- 3. TAU reject: There are various reasons for TAU reject. The action to be taken shall be as given in TS 24.301.

Storage of the full native EPS NAS security context, excluding the UE security capabilities and the keys K_{NASint} and K_{NASenc} , in the UE transitions to EMM-DEREGISTERED state is done as follows:

- a) If the ME does not have a full native EPS NAS security context in volatile memory, any existing native EPS NAS security context stored on the UICC or in non-volatile memory of the ME shall be marked as invalid.
- b) If the USIM supports EMM parameters storage, then the ME shall store the full native EPS NAS security context parameters on the USIM (except for K_{NASenc} and K_{NASint}), mark the native EPS NAS security context on the USIM as valid, and not keep any native EPS NAS security context in non-volatile ME memory.
- c) If the USIM does not support EMM parameters storage, then the ME shall store the full native EPS NAS security context (except for K_{NASenc} and K_{NASint}) in a non-volatile part of its memory, and mark the native EPS NAS security context in its non-volatile memory as valid.

For the case that the MME or the UE enter EMM-DEREGISTERED state without using any of the above procedures, the handling of the remaining authentication data shall be as specified in TS 24.301 [9].

7.2.5.2 Transition away from EMM-DEREGISTERED

7.2.5.2.1 General

When starting the transition away from EMM-DEREGISTERED state with the intent to eventually transitioning to EMM-REGISTERED state, if no current EPS NAS security context is available in the ME, the ME shall retrieve native EPS NAS security context stored on the USIM if the USIM supports EMM parameters storage and if the stored native EPS NAS security context on the USIM is marked as valid. If the USIM does not support EMM parameters storage the ME shall retrieve stored native EPS NAS security context from its non-volatile memory if the native EPS NAS security context is marked as valid. The ME shall derive the K_{NASint} and K_{NASenc} after retrieving the stored EPS NAS security context; see Annex A on NAS key derivation. The retrieved native EPS NAS security context with the derived K_{NASint} and K_{NASenc} shall then become the current EPS NAS security context.

When the ME is transitioning away from EMM-DEREGISTERED state with the intent to eventually transitioning to EMM-REGISTERED state, if the USIM supports EMM parameters storage, the ME shall mark the stored EPS NAS security context on the USIM as invalid. If the USIM does not support EMM parameters storage, the ME shall mark the stored EPS NAS security context in its non-volatile memory as invalid.

If the ME uses an EPS NAS security context to protect NAS messages, the NAS COUNT values are updated in the volatile memory of the ME. If the attempt to transition away from EMM-DEREGISTERED state with the intent to eventually transitioning to EMM-REGISTERED state fails, the ME shall store the (possibly updated) EPS NAS security context on the USIM or non-volatile ME memory and mark it as valid.

3GPP TS 33.401 version 9.8.0 Release 9

NOTE: The present specification only considers the states EMM-DEREGISTERED and EMM-REGISTERED and transitions between these two states. Other specifications define additional EMM states (see, e.g., TS 24.301 [9]).

When the UE transits from EMM-DEREGISTERED to EMM-REGISTERED/ECM-CONNECTED, there are two cases to consider, either a full native EPS NAS security context exists, or it does not.

7.2.5.2.2 With existing native EPS NAS security context

The UE shall transmit a NAS Attach Request message. This message is integrity protected and for the case that the EPS NAS security context used by the UE is non-current in the MME, the rules in clause 6.4 apply. Furthermore provided there is no NAS SMC procedure before the AS SMC the NAS COUNT of the Attach Request message shall be used to derive the K_{eNB} with the KDF as specified in Annex A. As a result of the NAS Attach Request, the eNB shall send an AS SMC to the UE to activate AS security. The K_{eNB} used, is derived in the current EPS NAS security context.

When the UE receives the AS SMC without having received a NAS Security Mode Command after the Attach Request, it shall use the NAS COUNT of the Attach Request message (i.e. the uplink NAS COUNT) that triggered the AS SMC to be sent as freshness parameter in the derivation of the K_{eNB} . From this K_{eNB} the RRC protection keys and the UP protection keys shall be derived as described in subclause 7.2.1.

The same procedure for refreshing K_{eNB} can be used regardless of the fact if the UE is connecting to the same MME to which it was connected previously or to a different MME. In case UE connects to a different MME and this MME supports different NAS algorithms, the NAS keys have to be re-derived in the MME with the new algorithm IDs as input using the KDF as specified in Annex A.

In addition, there is a need for the MME to send a NAS SMC to the UE to indicate the change of NAS algorithms and to take the re-derived NAS keys into use. The UE shall assure that the NAS keys used to verify the integrity of the NAS SMC are derived using the algorithm ID specified in the NAS SMC. The NAS SMC Command and NAS SMC Complete messages are protected with the new NAS keys.

If there is a NAS Security Mode Command after the Attach Request but before the AS SMC, the UE and MME use the NAS COUNT of the most recent NAS Security Mode Complete (i.e. the uplink NAS COUNT) and the related K_{ASME} as the parameter in the derivation of the K_{eNB} . From this K_{eNB} the RRC protection keys and the UP protection keys are derived as described in subclause 7.2.1.

7.2.5.2.3 With run of EPS AKA

If in the process described in clause 7.2.5.2.2, there is no full native EPS NAS security context available in the MME (i.e. either the UE has sent an unprotected Attach Request message or the UE has protected the Attach Request message with a current native EPS security context which no longer is stored in the MME) an EPS AKA run is required. If there is a full native EPS NAS security context available in the MME, then the MME may (according to MME policy) decide to run a new EPS AKA and a NAS SMC procedure (which activates the new EPS NAS security context based on the K_{ASME} derived during the EPS AKA run) after the Attach Request but before the corresponding AS SMC. The NAS (uplink and downlink) COUNTs are set to start values, and the start value of the uplink NAS COUNT shall be used as freshness parameter in the K_{eNB} derivation from the fresh K_{ASME} (after AKA) when UE receives AS SMC the K_{eNB} is derived from the current EPS NAS security context, i.e., the fresh K_{ASME} is used to derive the K_{eNB} The KDF as specified in Annex A shall be used to derive the K_{eNB} .

NOTE: Using the start value for the uplink NAS COUNT in this case cannot lead to the same combination of K_{ASME} and NAS COUNT being used twice. This is guaranteed by the fact that the first integrity protected NAS message the UE sends to the MME after AKA is the NAS SMC complete message.

The NAS SMC complete message shall include the start value of the uplink NAS COUNT that is used as freshness parameter in the K_{eNB} derivation and the K_{ASME} is fresh. After an AKA, a NAS SMC needs to be sent from the MME to the UE in order to take the new NAS keys into use. Both NAS SMC and NAS SMC Complete messages are protected with the new NAS keys.

7.2.6 Key handling in ECM-IDLE to ECM-CONNECTED and ECM-CONNECTED to ECM-IDLE transitions

7.2.6.1 ECM-IDLE to ECM-CONNECTED transition

The UE sends an initial NAS message to initiate transition from ECM-IDLE to ECM-CONNECTED state [9]. On transitions to ECM-CONNECTED, the MME should be able to check whether a new authentication is required, e.g. because of prior inter-provider handover.

When cryptographic protection for radio bearers is established RRC protection keys and UP protection keys shall be generated as described in subclause 7.2.1 while K_{ASME} is assumed to be already available in the MME.

The initial NAS message shall be integrity protected by the current EPS NAS security context if such exists. If no current EPS NAS security context exists the ME shall signal "no key available" in the initial NAS message.

 K_{ASME} may have been established in the MME as a result of an AKA run, or as a result of a security context transfer from another MME during handover or idle mode mobility. When the eNB releases the RRC connection the UE and the eNB shall delete the keys they store such that state in the network for ECM-IDLE state UEs will only be maintained in the MME.

7.2.6.2 Establishment of keys for cryptographically protected radio bearers

The procedure the UE uses to establish cryptographic protection for radio bearers is initiated by an (extended) NAS Service Request message or TAU Request message with the active flag set from the UE to the MME.

Upon receipt of the NAS message, if the MME does not require a NAS SMC procedure before initiating the S1-AP procedure INITIAL CONTEXT SETUP, the MME shall derive key K_{eNB} as specified in subclause A.3 using the NAS COUNT [9] corresponding to the NAS message and the K_{ASME} of the current EPS NAS security context. The MME shall further initialize the value of the Next hop Chaining Counter (NCC) to zero. The MME shall further derive a next hop parameter NH as specified in subclause A.4 using the newly derived K_{eNB} and the K_{ASME} as basis for the derivation. The MME shall further set the the value of the Next hop Chaining Counter (NCC) to one. This fresh {NH, NCC=1} pair shall be stored in the MME and shall be used for the next forward security key derivation. The MME shall communicate the K_{eNB} to the serving eNB in the S1-AP procedure INITIAL CONTEXT SETUP. The UE shall derive the K_{eNB} from the K_{ASME} of the current EPS NAS security context.

As a result of the (extended) NAS Service Request or TAU procedure, radio bearers are established, and the eNB sends an AS SMC to the UE. When the UE receives the AS SMC without having received a NAS Security Mode Command, it shall use the NAS uplink COUNT of the NAS message that triggered the AS SMC as freshness parameter in the derivation of the K_{eNB} . The KDF as specified in Annex A.3 shall be used for the K_{eNB} derivation using the K_{ASME} of the current EPS NAS security context. The UE shall further derive the NH parameter from the newly derived K_{eNB} and the K_{ASME} in the same way as the MME. From the K_{eNB} the RRC protection keys and the UP protection keys are derived by the UE and the eNB as described in subclause 6.2.

NOTE: At the UE, the NH derivation associated with NCC=1 could be delayed until the first handover performing vertical key derivation.

If the NAS procedure establishing radio bearers contains an EPS AKA run (which is optional), the NAS uplink and downlink COUNT for the new K_{ASME} shall be set to the start values (i.e. zero). If the NAS procedure establishing radio bearers contains a NAS SMC (which is optional), the value of the uplink NAS COUNT from the most recent NAS Security Mode Complete shall be used as freshness parameter in the K_{eNB} derivation from fresh K_{ASME} of the current EPS NAS security context when executing an AS SMC. The KDF as specified in Annex A.3 shall be used for the K_{eNB} derivation also in this case.

7.2.6.3 ECM-CONNECTED to ECM-IDLE transition

On ECM-CONNECTED to ECM-IDLE transitions the eNB does no longer need to store state information about the corresponding UE.

In particular, on ECM-CONNECTED to ECM-IDLE transitions:

- The eNB and the UE shall release all radio bearers and delete the AS security context.

- MME and the UE shall keep the EPS NAS security context stored with the following exception: if there is a new and an old K_{ASME} according to rules 3, 4, 8 or 9 in clause 7.2.10 of this specification then the MME and the UE shall delete the old K_{ASME} and the corresponding eKSI. The MME shall delete NH and NCC.

7.2.7 Key handling for the TAU procedure when registered in E-UTRAN

Before the UE can initiate the TAU procedure, the UE needs to transition to ECM-CONNECTED state. The UE shall use the current EPS security context to protect the TAU Request and include the corresponding GUTI and eKSI value. The TAU Request shall be integrity-protected, but not confidentiality-protected. UE shall use the current EPS security context algorithms to protect the TAU Request message. For the case that this security context is non-current in the MME, the rules in clause 6.4 apply.

If the "active flag" is not set in the TAU request, the TAU procedure does not establish any RRC or UP level security. Because of this, there is no need to derive any K_{eNB} in this case. If the "active flag" is set in the TAU request message, radio bearers will be established as part of the TAU procedure. In this case a K_{eNB} derivation is necessary, and if there was no subsequent NAS SMC, the uplink NAS COUNT of the TAU request message sent from the UE to the MME is used as freshness parameter in the K_{eNB} derivation using the KDF as specified in Annex A. The TAU request shall be integrity protected.

In the case an AKA is run successfully, the uplink and downlink NAS COUNT shall be set to the start values (i.e. zero).

In the case source and target MME use different NAS algorithms, the target MME re-derives the NAS keys from K_{ASME} with the new algorithm identities as input and provides the new algorithm identifiers within a NAS SMC. The UE shall assure that the NAS keys used to verify the integrity of the NAS SMC are derived using the algorithm identity specified in the NAS SMC.

If there is a NAS Security Mode Command after the TAU Request but before the AS SMC, the UE and MME use the NAS COUNT of the most recent NAS Security Mode Complete (i.e. the uplink NAS COUNT) and the related K_{ASME} as the parameter in the derivation of the K_{eNB} . From this K_{eNB} the RRC protection keys and the UP protection keys are derived as described in subclause 7.2.1.

7.2.8 Key handling in handover

7.2.8.1 General

7.2.8.1.1 Access stratum

The general principle of key handling at handovers is depicted in Figure 7.2.8.1-1.

Figure 7.2.8.1-1 Model for the handover key chaining

The following is an outline of the key handling model to clarify the intended structure of the key derivations. The detailed specification is provided in subclauses 7.2.8.3 and 7.2.8.4.

Whenever an initial AS security context needs to be established between UE and eNB, MME and the UE shall derive a K_{eNB} and a Next Hop parameter (NH). The K_{eNB} and the NH are derived from the K_{ASME} . A NH Chaining Counter (NCC) is associated with each K_{eNB} and NH parameter. Every K_{eNB} is associated with the NCC corresponding to the NH value from which it was derived. At initial setup, the K_{eNB} is derived directly from K_{ASME} , and is then considered to be associated with a virtual NH parameter with NCC value equal to zero. At initial setup, the derived NH value is associated with the NCC value one.

NOTE 1: At the UE, the NH derivation associated with NCC=1 could be delayed until the first handover performing vertical key derivation.

Whether the MME sends the K_{eNB} key or the {NH, NCC} pair to the serving eNB is described in detail in subclauses 7.2.8.3 and 7.2.8.4. The MME shall not send the NH value to eNB at the initial connection setup. The eNB shall initialize the NCC value to zero after receiving S1-AP Initial Context Setup Request message.

- NOTE 2: Since the MME does not send the NH value to eNB at the initial connection setup, the NH value associated with the NCC value one can not be used in the next X2 handover or the next intra-eNB handover, for the next X2 handover or the next intra-eNB handover the horizontal key derivation (see Figure 7.2.8.1-1) will apply.
- NOTE 3: One of the rules specified for the MME in subclause 7.2.8.4 of this specification states that the MME always computes a fresh {NH, NCC} pair that is given to the target eNB. An implication of this is that the first {NH, NCC} pair will never be used to derive a K_{eNB}. It only serves as an initial value for the NH chain.

The UE and the eNB use the K_{eNB} to secure the communication between each other. On handovers, the basis for the K_{eNB} that will be used between the UE and the target eNB, called K_{eNB}^* , is derived from either the currently active K_{eNB} or from the NH parameter. If K_{eNB}^* is derived from the currently active K_{eNB} this is referred to as a horizontal key derivation (see Figure 7.2.8.1-1) and if the K_{eNB}^* is derived from the NH parameter the derivation is referred to as a vertical key derivation (see Figure 7.2.8.1-1). On handovers with vertical key derivation the NH is further bound to the target PCI and its frequency EARFCN-DL before it is taken into use as the K_{eNB} in the target PCI and its frequency EARFCN-DL before it is further bound to the target PCI and its frequency EARFCN-DL before it is taken into use as the KeNB in the target PCI and its frequency EARFCN-DL before it is taken into use as the target PCI and its frequency EARFCN-DL before it is taken into use as the target PCI and its frequency EARFCN-DL before it is taken into use as the target PCI and its frequency EARFCN-DL before it is taken before it is taken into use as the KeNB in the target PCI and its frequency EARFCN-DL before it is taken into use as the target PCI and its frequency EARFCN-DL before it is taken before it is taken into use as the KeNB in the target PCI and its frequency EARFCN-DL before it is taken into use as the KeNB in the target eNB.

As NH parameters are only computable by the UE and the MME, it is arranged so that NH parameters are provided to eNBs from the MME in such a way that forward security can be achieved.

7.2.8.1.2 Non access stratum

A NAS aspect that needs to be considered is possible NAS algorithm change at MME change that could occur at a handover. At an eNB handover with MME relocation, there is the possibility that the source MME and the target MME do not support the same set of NAS algorithms or have different priorities regarding the use of NAS algorithms. In this case, the target MME re-derives the NAS keys from K_{ASME} using the NAS algorithm identities as input to the NAS key derivation functions (see Annex A) and sends NAS SMC. All inputs, in particular the K_{ASME} , will be the same in the re-derivation except for the NAS algorithm identity.

In case the target MME decides to use NAS algorithms different from the ones used by the source MME, a NAS SMC including eKSI (new or current value depending on whether AKA was run or not) shall be sent from the MME to the UE.

This NAS Key and algorithm handling also applies to other MME changes e.g. TAU with MME changes.

- NOTE: It is per operator's policy how to configure selection of handover types. Depending on an operator's security requirements, the operator can decide whether to have X2 or S1 handovers for a particular eNB according to the security characteristics of a particular eNB.
- 7.2.8.2 Void

7.2.8.3 Key derivations for context modification procedure

As outlined in subclause 7.2.8.1, whenever a fresh K_{eNB} is calculated from the K_{ASME} (as described in Annex A.3), the MME shall transfer the K_{eNB} to the serving eNB in a message modifying the security context in the eNB. The MME and the UE shall also compute the NH parameter from the K_{ASME} and the fresh K_{eNB} as described in Annex A.4 according to the rules in clause 7.2.9.2. An NCC value 1 is associated with the NH parameter derived from the fresh K_{eNB} and NCC value 0 with the K_{eNB} . The UE shall compute K_{eNB} and NH in the same way as the MME. From the newly computed K_{eNB} , the eNB and the UE shall compute the temporary K_{eNB}^* and then the final K_{eNB} from that K_{eNB}^* as described in clause 7.2.9.2.

- NOTE 1: Since MME does not send the NH value to eNB in S1 UE CONTEXT MODIFICATION REQUEST, the NH value associated with the NCC value one can not be used in the next X2 handover or the next intraeNB handover. So for the next X2 handover or the next intra-eNB handover the horizontal key derivation (see Figure 7.2.8.1-1) will apply.
- NOTE 2: One of the rules specified for the MME in subclause 7.2.8.4 of this specification states that the MME always computes a fresh {NH, NCC} pair that is given to the target eNB. An implication of this is that the first {NH, NCC} pair, i.e., the one with NCC equal to 1 will never be used to derive a K_{eNB}. It only serves as an initial value for the NH chain.
- NOTE 3: At the UE, the NH derivation associated with NCC=1 could be delayed until the first handover performing vertical key derivation.

7.2.8.4 Key derivations during handovers

7.2.8.4.1 Intra-eNB Handover

When the eNB decides to perform an intra-eNB handover it shall derive K_{eNB}^* as in Annex A.5 using target PCI, its frequency EARFCN-DL, and either NH or the current K_{eNB} depending on the following criteria: the eNB shall use the NH for deriving K_{eNB}^* if an unused {NH, NCC} pair is available in the eNB (this is referred to as a vertical key derivation), otherwise if no unused {NH, NCC} pair is available in the eNB, the eNB shall derive K_{eNB}^* from the current K_{eNB} (this is referred to as a horizontal key derivation).

The eNB shall use the K_{eNB}^* as the K_{eNB} after handover. The eNB shall send the NCC used for K_{eNB}^* derivation to UE in HO Command message.

7.2.8.4.2 X2-handover

As in intra-eNB handovers, for X2 handovers the source eNB shall perform a vertical key derivation in case it has an unused {NH, NCC} pair. The source eNB shall first compute K_{eNB}^{*} from target PCI, its frequency EARFCN-DL, and

either from currently active K_{eNB} in case of horizontal key derivation or from the NH in case of vertical key derivation as described in Annex A.5.

Next the source eNB shall forward the { K_{eNB}^* , NCC} pair to the target eNB. The target eNB shall use the received K_{eNB}^* directly as K_{eNB} to be used with the UE. The target eNB shall associate the NCC value received from source eNB with the K_{eNB} . The target eNB shall include the received NCC into the prepared HO Command message, which is sent back to the source eNB in a transparent container and forwarded to the UE by source eNB.

When the target eNB has completed the handover signaling with the UE, it shall send a S1 PATH SWITCH REQUEST to the MME. Upon reception of the S1 PATH SWITCH REQUEST, the MME shall increase its locally kept NCC value by one and compute a new fresh NH by using the K_{ASME} and its locally kept NH value as input to the function defined in Annex A.4. The MME shall then send the newly computed {NH, NCC} pair to the target eNB in the S1 PATH SWITCH REQUEST ACKNOWLEDGE message. The target eNB shall store the received {NH, NCC} pair for further handovers and remove other existing unused stored {NH, NCC} pairs if any.

NOTE: Because the path switch message is transmitted after the radio link handover, it can only be used to provide keying material for the next handover procedure and target eNB. Thus, for X2-handovers key separation happens only after two hops because the source eNB knows the target eNB keys. The target eNB can immediately initiate an intra-cell handover to take the new NH into use once the new NH has arrived in the S1 PATH SWITCH REQUEST ACKNOWLEDGE.

7.2.8.4.3 S1-Handover

Upon reception of the HANDOVER REQUIRED message the source MME shall increase its locally kept NCC value by one and compute a fresh NH from its stored data using the function defined in Annex A.4. The source MME shall store that fresh pair and send it to the target MME in the S10 FORWARD RELOCATION REQUEST message. The S10 FORWARD RELOCATION REQUEST message shall in addition contain the K_{ASME} that is currently used to compute {NH, NCC} pairs and its corresponding eKSI.

The target MME shall store locally the {NH, NCC} pair received from the source MME.

The target MME shall then send the received {NH, NCC} pair to the target eNB within the S1 HANDOVER REQUEST.

Upon receipt of the S1 HANDOVER REQUEST from the target MME, the target eNB shall compute the K_{eNB} to be used with the UE by performing the key derivation defined in Annex A.5 with the fresh{NH, NCC} pair in the S1 HANDOVER REQUEST and the target PCI and its frequency EARFCN-DL. The target eNB shall associate the NCC value received from MME with the K_{eNB} . The target eNB shall include the NCC value from the received {NH, NCC} pair into the HO Command to the UE and remove any existing unused stored {NH, NCC} pairs.

NOTE: The source MME may be the same as the target MME in the description in this subclause. If so the single MME performs the roles of both the source and target MME, i.e. the MME calculates and stores the fresh {NH, NCC} pair and sends this to the target eNB.

For S1-handover, the source eNB shall include AS algorithms used in the source cell (ciphering and integrity algorithms) in the source to target transparent container that shall be sent to the target eNB. The AS algorithms used by in the source cell are provided to the target eNB so that it can decipher and integrity verify the RRCReestablishmentComplete message on SRB1 in the potential RRCConnectionRe-establishment procedure.

7.2.8.4.4 UE handling

The UE behaviour is the same regardless if the handover is S1, X2 or intra-eNB.

If the NCC value the UE received in the HO Command message from target eNB via source eNB is equal to the NCC value associated with the currently active K_{eNB} , the UE shall derive the K_{eNB}^* from the currently active K_{eNB} and the target PCI and its frequency EARFCN-DL using the function defined in Annex A.5.

If the UE received an NCC value that was different from the NCC associated with the currently active K_{eNB} , the UE shall first synchronize the locally kept NH parameter by computing the function defined in Annex A.4 iteratively (and increasing the NCC value until it matches the NCC value received from the source eNB via the HO command message. When the NCC values match, the UE shall compute the K_{eNB}^{*} from the synchronized NH parameter and the target PCI and its frequency EARFCN-DL using the function defined in Annex A.5.

The UE shall use the K_{eNB}^* as the K_{eNB} when communicating with the target eNB.

42

7.2.9 Key-change-on-the fly

7.2.9.1 General

Key-change-on-the fly consists of re-keying or key-refresh.

Key refresh shall be possible for K_{eNB} , $K_{RRC-enc}$, $K_{RRC-int}$, and K_{UP-enc} and shall be initiated by the eNB when a PDCP COUNTs is about to be re-used with the same Radio Bearer identity and with the same K_{eNB} . The procedure is described in clause 7.2.9.3.

Re-keying shall be possible for the K_{eNB} , $K_{RRC-enc}$, $K_{RRC-int}$, and K_{UP-enc} . This re-keying shall be initiated by the MME when an EPS AS security context different from the currently active one shall be activated. The procedures for doing this are described in clause 7.2.9.2.

Re-keying shall be possible for $K_{NAS-enc}$ and $K_{NAS-int}$. Re-keying of $K_{NAS-enc}$ and $K_{NAS-int}$ shall be initiated by the MME when a EPS NAS security context different from the currently active one shall be activated. The procedures for doing this are described in clause 7.2.9.4.

Re-keying of the entire EPS key hierarchy including K_{ASME} shall be achieved by first re-keying K_{ASME} , then $K_{NAS-enc}$ and $K_{NAS-int}$, followed by re-keying of the K_{eNB} and derived keys. For NAS key change-on-on-the fly, activation of NAS keys is accomplished by a NAS SMC procedure.

AS Key change on-the-fly is accomplished using a procedure based on intra-cell handover. The following AS key changes on-the-fly shall be possible: local K_{eNB} refresh (performed when PDCP COUNTs are about to wrap around), K_{eNB} re-keying performed after an AKA run, activation of a native context after handover from UTRAN or GERAN.

7.2.9.2 K_{eNB} re-keying

The re-keying procedure is initiated by the MME after a successful AKA run with the UE to activate a partial native EPS security context, or to re-activate a non-current full native EPS security context after handover from GERAN or UTRAN according to subclauses 9.2.2.1 and 10.3.2.

In case the procedure is initiated by the MME after a successful AKA run with the UE, the MME derives the new K_{eNB} using the key derivation function as specified in Annex A.3 using the new K_{ASME} and the uplink NAS COUNT used in the most recent NAS Security Mode Complete message. The K_{eNB} is sent to the eNB after a successfully completed NAS SMC in a S1 AP UE CONTEXT MODIFICATION REQUEST message triggering the eNB to perform the rekeying. The eNB runs the key-change-on-the-fly procedure with the UE. During this procedure the eNB shall indicate to the UE that a key change on-the-fly is taking place. The procedure used is based on an intra-cell handover, and hence the same K_{eNB} derivation steps shall be taken as in a normal handover procedure.

When the UE receives an indication that the procedure is a key change on-the-fly procedure, the UE shall use the K_{ASME} from the current EPS NAS security context as the basis for K_{eNB} derivations.

NOTE 1: To perform a key change on-the-fly of the entire key hierarchy, the MME has to change the EPS NAS security context before changing the AS security context.

If the UE has determined that the eKSI has changed, the UE shall derive a temporary K_{eNB} by applying the key derivation function as specified in Annex A.3, using the uplink NAS COUNT in the most recent NAS Security Mode Complete message and the new K_{ASME} as input. From this temporary K_{eNB} the UE shall derive the K_{eNB}^* as normal (see Annex A). The eNB shall take the K_{eNB} it received from the MME, which is equal to the temporary K_{eNB} , as basis for its K_{eNB}^* derivations. From this step onwards, the key derivations continue as in a normal handover.

If the AS level re-keying fails, then the MME shall complete another NAS security mode procedure before initiating a new AS level re-keying. This ensures that a fresh K_{eNB} is used.

In case the re-keying procedure is initiated by the MME to re-activate a non-current full native EPS security context after handover from GERAN or UTRAN the same procedure as above applies.

The NH parameter shall be handled according to the following rules:

- UE and MME shall use NH derived from old K_{ASME} before the context modification is complete, i.e. for the UE when it sends the RRC Connection Reconfiguration Complete, and for the MME when it receives the UE CONTEXT MODIFICATION RESPONSE. In particular, the MME shall send an NH derived from old K_{ASME} in

the S1AP HANDOVER RESOURCE ALLOCATION, S10 FORWARD RELOCATION, and S1AP PATH SWITCH REQUEST ACKNOWLEDGE messages before the context modification is complete.

- The eNB shall delete any old NH upon completion of the context modification.
- The UE and MME shall delete any old NH upon completion of the context modification. After the completion of the context modification, the UE and the MME shall derive any new NH parameters from the new K_{eNB} and the new K_{ASME} according to Annex A.4.

7.2.9.3 KeNB refresh

This procedure is based on an intra-cell handover. The K_{eNB} chaining that is performed during a handover ensures that the K_{eNB} is re-freshed w.r.t. the RRC and UP COUNT after the procedure.

7.2.9.4 NAS key re-keying

After an AKA has taken place, new NAS keys from a new K_{ASME} shall be derived, according to Annex A.7.

To re-activate a non-current full native EPS security context after handover from GERAN or UTRAN, cf. clause 9.2.2 B step 7, the UE and the MME take the NAS keys into use by running a NAS SMC procedure according to clause 7.2.4.5.

MME shall activate fresh NAS keys from an EPS AKA run or activate native security context with sufficiently low NAS COUNT values before the NAS uplink or downlink COUNT wraps around with the current security context.

7.2.10 Rules on Concurrent Running of Security Procedures

Concurrent runs of security procedures may, in certain situations, lead to mismatches between security contexts in the network and the UE. In order to avoid such mismatches, the following rules shall be adhered to:

- 1. MME shall not initiate any of the S1 procedures Initial Context Setup or UE Context Modification including a new K_{eNB} towards a UE if a NAS Security Mode Command procedure is ongoing with the UE.
- 2. The MME shall not initiate a NAS Security Mode Command towards a UE if one of the S1 procedures Initial Context Setup or UE Context Modification including a new K_{eNB} is ongoing with the UE.
- 3. When the UE has cryptographically protected radio bearers established and the MME has initiated a NAS SMC procedure in order to take a new K_{ASME} into use, the MME shall continue to include AS security context parameters based on the old K_{ASME} in the HANDOVER REQUEST or PATH SWITCH REQUEST ACKNOWLEDGE message, until the MME takes a K_{eNB} derived from the new K_{ASME} into use by means of a UE Context Modification procedure.
- 4. When the UE has cryptographically protected radio bearers established and has received a NAS SMC message in order to take a new K_{ASME} into use, the UE shall continue to use AS security context parameters based on the old K_{ASME} in handover until the network indicates in an RRCConnectionReconfiguration procedure to take a K_{eNB} derived from the new K_{ASME} into use.
- 5. The source eNB shall reject an S1 UE Context Modification Request when the eNB has initiated, but not yet completed, an inter-eNB handover. When a RRCConnectionReconfiguration procedure triggered by a UE Context Modification is ongoing the source eNB shall wait for the completion of this procedure before initiating any further handover procedure.
- 6. When the MME has initiated a NAS SMC procedure in order to take a new K_{ASME} into use and receives a request for an inter-MME handover or an inter-RAT handover from the serving eNB, the MME shall wait for the completion of the NAS SMC procedure before sending an S10 FORWARD RELOCATION message or initiating an inter-RAT handover.
- 7. When the MME has initiated a UE Context Modification procedure in order to take a new K_{eNB} into use and receives a request for an inter-MME handover from the serving eNB, the MME shall wait for the (successful or unsuccessful) completion of the UE Context Modification procedure before sending an S10 FORWARD RELOCATION message.

- 8. When the MME has successfully performed a NAS SMC procedure taking a new K_{ASME} into use, but has not yet successfully performed a UE Context Modification procedure, which takes a K_{eNB} derived from the new K_{ASME} into use, the MME shall include both the old K_{ASME} with the corresponding eKSI, NH, and NCC, and a full EPS NAS security context based on the new K_{ASME} in the S10 FORWARD RELOCATION message.
- 9. When an MME receives a S10 FORWARD RELOCATION message including both the old K_{ASME} with the corresponding eKSI, NH, and NCC, and a full EPS NAS security context based on the new K_{ASME} the MME shall use the new K_{ASME} in NAS procedures, but shall continue to include AS security context parameters based on the old K_{ASME} in the HANDOVER REQUEST or PATH SWITCH REQUEST ACKNOWLEDGE message until the completion of a UE Context Modification procedure, which takes a K_{eNB} derived from the new K_{ASME} into use.
- 10. Once the source MME has sent an S10 FORWARD RELOCATION message to the target MME at an inter-MME handover, the source MME shall not send any downlink NAS messages to the UE until it is aware that the handover has either failed or has been cancelled.

7.3 UP security mechanisms

7.3.1 UP confidentiality mechanisms

The user plane data is ciphered by the PDCP protocol between the UE and the eNB as specified in TS 36.323 [12]..

The use and mode of operation of the 128-EEA algorithms are specified in Annex B.

The input parameters to the 128-bit EEA algorithms as described in Annex B are an 128-bit cipher key K_{UPenc} as KEY, a 5-bit bearer identity BEARER which value is assigned as specified by TS 36.323 [12], the 1-bit direction of transmission DIRECTION, the length of the keystream required LENGTH and a bearer specific, time and direction dependent 32-bit input COUNT which corresponds to the 32-bit PDCP COUNT.

7.4 RRC security mechanisms

7.4.1 RRC integrity mechanisms

RRC integrity protection shall be provided by the PDCP layer between UE and eNB and no layers below PDCP shall be integrity protected. Replay protection shall be activated when integrity protection is activated (except for when the selected integrity protection algorithm is EIA0, see Annex B). Replay protection shall ensure that the receiver only accepts each particular incoming PDCP COUNT value once using the same AS security context.

The use and mode of operation of the 128-EIA algorithms are specified in Annex B.

The input parameters to the 128-bit EIA algorithms as described in Annex B are an 128-bit integrity key K_{RRCint} as KEY, a 5-bit bearer identity BEARER which value is assigned as specified by TS 36.323 [12], the 1-bit direction of transmission DIRECTION and a bearer specific, time and direction dependent 32-bit input COUNT which corresponds to the 32-bit PDCP COUNT.

The supervision of failed RRC integrity checks shall be performed both in the ME and the eNB. In case of failed integrity check (i.e. faulty or missing MAC-I) is detected after the start of integrity protection, the concerned message shall be discarded. This can happen on the eNB side or on the ME side.

NOTE: This text does not imply that the concerned message is silently discarded. In fact, TS 36.331 [21] specifies that the UE shall trigger a recovery procedure upon detection of a failed RRC integrity check. When the cause for integrity protection failure is not a context mismatch, such as a key or HFN mismatch, the run of a recovery procedure unnecessarily adds load to the system. However, in the absence of a means for the UE to reliably detect the cause of an integrity protection failure and the fact that the only identified consequence of an active attack is limited to non-persistent DoS effects, priority was given to a procedure allowing recovery from the deadlock caused by a context mismatch.

7.4.2 RRC confidentiality mechanisms

RRC confidentiality protection is provided by the PDCP layer between UE and eNB.

The use and mode of operation of the 128-EEA algorithms are specified in Annex B.

The input parameters to the 128-bit EEA algorithms as described in Annex B are an 128-bit cipher Key K_{RRCenc} as KEY, a 5-bit bearer identity BEARER which corresponds to the radio bearer identity, the 1-bit direction of transmission DIRECTION, the length of the keystream required LENGTH and a bearer specific, time and direction dependent 32-bit input COUNT which corresponds to the 32-bit PDCP COUNT.

7.4.3 K_{eNB}* and Token Preparation for the RRCConnectionReestablishment Procedure

The K_{eNB}^* and token calculation at handover preparation are cell specific instead of eNB specific. At potential RRC Connection re-establishment (e.g, in handover failure case), the UE may select a cell different from the target cell to initiate the re-establishment procedure. To ensure that the UE RRCConnectionRe-establishment attempt is successful when the UE selects another cell under the control of the target eNB at handover preparation, the serving eNB could prepare multiple K_{eNB}^* s and tokens for multiple cells which are under the control of the target eNB. The serving eNB may prepare cells belonging to the serving eNB itself.

The preparation of these cells includes sending security context containing K_{eNB} *s and tokens for each cell to be prepared, as well as the corresponding NCC, the UE EPS security capabilities, and the security algorithms used in the source cell for computing the token, to the target eNB. The source eNB shall derive the K_{eNB} *s as described in Annex A.5 based on the corresponding target cell"s physical cell ID and frequency EARFCN-DL.

In order to calculate the token, the source eNB shall use the negotiated EIA-algorithm from the AS Security context from the source eNB with the following inputs: source C-RNTI, source PCI and target Cell-ID as defined by *VarShortMAC-Input* in TS 36.331 [21], where source PCI and source C-RNTI are associated with the cell the UE last had an active RRC connection with and target cell ID is the identity of the target cell where the RRCConnectionReestablishmentRequest is sent to.

- KEY shall be set to K_{RRCint} of the source cell;
- all BEARER bits shall be set to 1;
- DIRECTION bit shall be set to 1;
- all COUNT bits shall be set to 1.

The token shall be the 16 least significant bits of the output of the used integrity algorithm.

To avoid that the UE cannot perform the RRC re-establishment procedure if there is a failure during a handover or a connection re-establishment, the UE shall keep the K_{eNB} used in the source cell until the handover or a connection re-establishment has completed successfully or until the UE has deleted the K_{eNB} due to other rules in this specification (e.g., due to transitioning to ECM-IDLE).

For X2 handover, the target eNB shall use these received multiple K_{eNB} *s. But for S1 handover, the target eNB discards the multiple K_{eNB} *s received from the source eNB, and derives the K_{eNB} *s as described in Annex A.5 based on the received fresh {NH, NCC} pair from MME for forward security purpose.

When an RRCConnectionReestablishmentRequest is initiated by the UE, the RRCConnectionReestablishmentRequest shall contain the token corresponding to the cell the UE tries to reconnect to. This message is transmitted over SRB0 and hence not integrity protected.

The target eNB receiving the RRCConnectionReestablishmentRequest shall respond with an RRCConnectionReestablishment message containing the NCC received during the preparation phase if the token is valid, otherwise the target eNB shall reply with an RRCConnectionReestablishmentReject message. The

RRCConnectionReestablishment and RRCConnectionReestablishmentReject messages are also sent on SRB0 and hence not integrity protected. Next the target eNB and UE shall do the following: The UE shall firstly synchronize the locally kept NH parameter as defined in Annex A.4 if the received NCC value is different from the current NCC value in the UE itself. Then the UE shall derive K_{eNB}^{*} as described in Annex A.5 based on the selected cell's physical cell ID and its frequency EARFCN-DL. The UE shall use this K_{eNB}^{*} as K_{eNB} . The eNB uses the K_{eNB}^{*} corresponding to the selected cell as K_{eNB} . Then, UE and eNB shall derive and activate keys for integrity protection and verification from this K_{eNB} and the AS algorithms (ciphering and integrity algorithms) obtained during handover preparation procedures which were used in source eNB. Even if the AS algorithms used by the source eNB do not match with the target eNB local algorithm priority list the source eNB selected AS algorithms shall take precedence when running the RRCConnectionRe-establishment procedure. The target eNB and UE should refresh the selected AS algorithms and the AS keys based on local prioritized algorithms after the RRCConnectionRe-establishment procedure.

NOTE: When the AS algorithms transferred by source eNB are not supported by the target eNB, the target eNB will fail to decipher or integrity verify the RRCReestablishmentComplete message on SRB1. As a result, the RRCConnectionRe-establishment procedure will fail.

The UE shall respond with an RRCReestablishmentComplete on SRB1, integrity protected and ciphered using these new keys. The RRCConnectionReconfiguration procedure used to re-establish the remaining radio bearers shall only include integrity protected and ciphered messages.

7.5 Signalling procedure for periodic local authentication

The following procedure is used optionally by the eNB to periodically perform a local authentication. At the same time, the amount of data sent during the AS connection is periodically checked by the eNB and the UE for both up and down streams. If UE receives the Counter Check request, it shall respond with Counter Check Response message.

The eNB is monitoring the PDCP COUNT values associated to each radio bearer. The procedure is triggered whenever any of these values reaches a critical checking value. The granularity of these checking values and the values themselves are defined by the visited network. All messages in the procedure are integrity protected.

Figure 7.5-1: eNB periodic local authentication procedure

- 1. When a checking value is reached (e.g. the value in some fixed bit position in the hyperframe number is changed), a Counter Check message is sent by the eNB. The Counter Check message contains the most significant parts of the PDCP COUNT values (which reflect amount of data sent and received) from each active radio bearer.
- 2. The UE compares the PDCP COUNT values received in the Counter Check message with the values of its radio bearers. Different UE PDCP COUNT values are included within the Counter Check Response message.
- 3. If the eNB receives a counter check response message that does not contain any PDCP COUNT values, the procedure ends. If the eNB receives a counter check response that contains one or several PDCP COUNT values, the eNB may release the connection or report the difference of the PDCP COUNT values for the serving MME or O&M server for further traffic analysis for e.g. detecting the attacker.

8 Security mechanisms for non-access stratum signalling

8.1 NAS integrity mechanisms

Integrity protection for NAS signalling messages shall be provided as part of the NAS protocol.

8.1.1 NAS input parameters and mechanism

Input parameters to the NAS 128-bit integrity algorithms as described in Annex B are an 128-bit integrity key K_{NASint} as KEY an 5-bit bearer identity BEARER which shall equal the constant value 0x00, the direction of transmission DIRECTION, and a bearer specific, time and direction dependent 32-bit input COUNT which is constructed as follows:

COUNT := 0x00 || NAS OVERFLOW || NAS SQN

Where

- the leftmost 8 bits are padding bits including all zeros.
- NAS OVERFLOW is a 16-bit value which is incremented each time the NAS SQN is incremented from the maximum value.
- NAS SQN is the 8-bit sequence number carried within each NAS message.
- NOTE: The BEARER identity is not necessary since there is only one NAS signalling connection per pair of MME and UE, but is included as a constant value so that the input parameters for AS and NAS will be the same, which simplifies specification and implementation work.

The use and mode of operation of the 128-bit integrity algorithms are specified in Annex B.

The supervision of failed NAS integrity checks shall be performed both in the ME and the MME. In case of failed integrity check (i.e. faulty or missing NAS-MAC) is detected after the start of NAS integrity protection, the concerned message shall be discarded except for some NAS messages specified in TS 24.301 [9]. For those exceptions the MME shall take the actions specified in TS 24.301 [9] when receiving a NAS message with faulty or missing NAS-MAC. Discarding NAS messages can happen on the MME side or on the ME side.

8.1.2 NAS integrity activation

NAS integrity shall be activated using the NAS SMC procedure or after a handover to E-UTRAN from UTRAN/GERAN. Replay protection shall be activated when integrity protection is activated (except for when the selected integrity protection algorithm is EIA0, see Annex B). Replay protection shall ensure that the receiver only accepts each particular incoming NAS COUNT value once using the same NAS security context. Once NAS integrity has been activated, NAS messages without integrity protection shall only be accepted by the UE or MME. Before NAS integrity has been activated, NAS messages without integrity protection as specified in TS 24.301 [9]. While some NAS messages need to be accepted by the UE without integrity protection, the MME shall only send a reject message that causes the CSG list on the UE to be modified after the start of NAS security. The UE shall discard any message modifying the CSG list if it is not integrity protected.

NAS integrity stays activated until the EPS security context is deleted in either the UE or MME. In particular the NAS service request shall always be integrity protected and the NAS attach request message shall be integrity protected if the EPS security context is not deleted while UE is in EMM-DEREGISTERED. The length of the NAS-MAC is 32 bit. The full NAS-MAC shall be appended to all integrity protected messages except for the NAS service request. Only the 16 least significant bits of the 32 bit NAS-MAC shall be appended to the NAS service request message.

The use and mode of operation of the 128-EIA algorithms are specified in Annex B.

8.2 NAS confidentiality mechanisms

The input parameters for the NAS 128-bit ciphering algorithms shall be the same as the ones used for NAS integrity protection as described in clause 8.1, with the exception that a different key, K_{NASenc} , is used as KEY, and there is an additional input parameter, namely the length of the key stream to be generated by the encryption algorithms.

The use and mode of operation of the 128-bit ciphering algorithms are specified in Annex B.

9 Security interworking between E-UTRAN and UTRAN

9.1 RAU and TAU procedures

9.1.1 RAU procedures in UTRAN

This subclause covers both the cases of idle mode mobility from E-UTRAN to UTRAN and of Idle Mode Signaling Reduction (ISR), as defined in TS 23.401 [2].

NOTE 1: TS 23.401 states conditions under which a valid P-TMSI or a P-TMSI that is mapped from a valid GUTI ('mapped GUTI') is inserted in the Information Element 'old P-TMSI' in the Routing Area Update Request. It depends on the old P-TMSI which security context can be taken into use after completion of the Routing Area Update procedure.

Use of an existingUMTS security context

If the UE sends the RAU Request with the "old P-TMSI" Information Element including a valid P-TMSI it shall also include the KSI relating to this P-TMSI. This KSI is associated with the UMTS security context stored on the UE, and it indicates this fact to the SGSN. In this case the UE shall include P-TMSI signature into the RAU Request if a P-TMSI signature was assigned by the old SGSN. If the network does not have a valid security context for this KSI it shall run AKA. In case of an SGSN change keys from the old SGSN shall overwrite keys in the new SGSN if any.

NOTE 2: if the UE has a valid UMTS security context then this context is stored on the USIM according to TS 33.102 [4].

Mapping of EPS security context to UMTS security context

If the UE sends the RAU Request with the "old P-TMSI" Information Element including mapped GUTI it shall also include the KSI equal to the value of the eKSI associated with the current EPS security context (cf. clause 3). The UE shall include a truncated NAS-token, as defined in this clause further below, into the P-TMSI signature IE. The MME shall transfer UE's UTRAN and GERAN security capabilities and CK' || IK' with KSI equal to the value of the eKSI associated with the current EPS security context to SGSN with Context Response/SGSN Context Response message. The MME and UE shall derive CK' and IK' from the K_{ASME} and the NAS uplink COUNT value corresponding to the truncated NAS-token received by the MME from SGSN as specified in Annex A. Keys CK' and IK' and KSI sent from the MME shall replace all the UTRAN PS key parameters CK, IK, s KSI in the target SGSN if any. Keys CK' and IK' and the KSI shall replace all the currently stored UTRAN PS key parameters CK, IK, KSI values on both USIM and ME. The handling of START_{PS} shall comply with the rules in 3GPP TS 25.331 [24]. The UE may set the START_{PS} value to 0 if it is done before establishment of the RRC connection.

The ME shall use CK' and IK' to derive the GPRS Kc using the c3 function specified in 3GPP TS 33.102 [4]. The ME shall assign the eKSI value (associated with CK" and IK") to the GPRS CKSN. The ME shall update the USIM and ME with the new GPRS Kc and GPRS CKSN.

NOTE 3: The new derived security context (including CK" and IK") replacing the old stored values in the USIM is for allowing to reuse the derived security context without invoking the authentication procedure in the subsequent connection set-ups , and also for avoiding that one KSI indicates to two different key sets and consequently leads to security context desynchronization.

- NOTE 4: An operator concerned about the security of keys received from another operator may want to enforce a policy in SGSN to run a UMTS AKA as soon as possible after the run of an idle mode mobility procedure. An example of ensuring this is the deletion of the mapped UMTS security context in the SGSN after the completion of the idle mode mobility procedure.
- NOTE 5: Due to replacing all the UTRAN PS key parameters CK, IK, KSI with CK", IK" and eKSI on USIM and in ME, a new GPRS Kc needs to be derived from the new UTRAN PS key parameters CK and IK (i.e. CK" and IK"), which is part of the new UMTS security context as well, as any old GPRS Kc stored on USIM and in ME belongs to an old UMTS security context and can no longer be taken into use.

SGSN shall include the allowed security algorithm and transfer them to RNC. An SMC shall be sent to the UE containing the selected algorithms.

The x bits available in the P-TMSI signature field (at minimum 16 bits) shall be filled with the truncated NAS-token, which is defined as the x least significant bits of the NAS-token.

The NAS-token is derived as specified in Annex A.9. The UE shall use the uplink NAS COUNT value that it would use in the next NAS message to calculate the NAS-token and increase the stored uplink NAS COUNT value by 1.

SGSN shall forward the P-TMSI signature including the truncated NAS token to the old MME, which compares the received bits of the truncated NAS-token with the corresponding bits of a NAS-token generated in the MME, for the UE identified within the context request. If they match, the context request message is authenticated and authorized and MME shall provide the needed information for the SGSN. Old MME shall respond with an appropriate error cause if it does not match the value stored in the old MME. This should initiate the security functions in the new SGSN.

To avoid possible race condition problems, the MME shall compare the received truncated NAS-token with the x least significant bits of NAS-tokens generated from the current NAS uplink COUNT value up to current NAS uplink COUNT value +L, i.e. the interval [current NAS uplink COUNT, current NAS uplink COUNT+L]. A suitable value for the parameter L can be configured by the network operator. MME shall not accept the same NAS-token for the same UE twice except in retransmission cases happening for the same mobility event. If the MME finds a match, it shall set the stored uplink NAS COUNT value as though it had successfully received an integrity protected NAS message with the uplink NAS COUNT value that created the match.

9.1.2 TAU procedures in E-UTRAN

This subclause covers both the cases of idle mode mobility from UTRAN to E-UTRAN and of Idle Mode Signaling Reduction, as defined in TS 23.401 [2].

The TAU Request and ATTACH Request message shall include the UE security capabilities. The MME shall store these UE security capabilities for future use. The MME shall not make use of any UE security capabilities received from the SGSN.

NOTE 1: TS 23.401 states conditions under which a valid GUTI or a GUTI that is mapped from a valid P-TMSI is inserted in the Information Element 'old GUTI' in the Tracking Area Update Request. The value in the 'old' GUTI IE informs the MME, which SGSN/MME to fetch the UE context from.

Case 1: P-TMSI not included in 'old GUTI' IE in TAU Request

This case is identical to that described in clause 7.2.7.

Case 2: Mapped P-TMSI included in 'old GUTI' IE in TAU Request

The UE shall include in the TAU Request:

- the KSI with corresponding P-TMSI and old RAI to point to the right source SGSN and key set there. This allows the UE and MME to generate the mapped EPS NAS security context, as described below, if current EPS NAS security context is not available in the UE and network. The KSI shall correspond to the set of keys most recently generated (either by a successful UMTS AKA run in UTRAN (which may or may not yet have been taken into use by the UE and SGSN) or a UMTS security context mapped from an EPS NAS security context during a previous visit in UTRAN).
- a P-TMSI signature, if the UE was previously connected to UTRAN where the SGSN assigned a P-TMSI signature to the UE

- a 32bit NONCE_{UE} (see clause A.11 for requirements on the randomness of NONCE_{UE}).

If the UE has a current EPS NAS security context, then it shall include the corresponding GUTI and eKSI value in the TAU Request. The TAU Request shall be integrity-protected, but not confidentiality-protected. The UE shall use the current EPS NAS security context algorithms to protect the TAU Request message.

- NOTE 2: The current EPS NAS security context may be of type "mapped", and hence the value of the eKSI be of type "KSI_{SGSN}". This value of KSI_{SGSN} may be different from the KSI pointing to the set of keys most recently generated in UTRAN as an UMTS AKA run may have happened in UTRAN after the current mapped EPS NAS security context indicated by the eKSI with the value KSI_{SGSN} was generated
- NOTE 3: The UE has a current EPS NAS security context in the following scenario: a UE established a current EPS NAS security context during a previous visit to EPS, then moves to UTRAN/GERAN from E-UTRAN and storing the current EPS NAS security context. When the UE moves back to E-UTRAN there is a current EPS NAS security context.

If a current EPS NAS security context is not available in the UE, the UE shall send the TAU request unprotected.

If the MME received a P-TMSI signature from the UE, the MME shall include that P-TMSI signature in the Context Request message sent to the SGSN. The SGSN shall transfer CK || IK to MME in the Context Response/SGSN Context Response message. In case the MM context in the Context Response/SGSN Context Response indicates GSM security mode, the MME shall abort the procedure.

In case the TAU Request was protected and the MME has the indicated EPS NAS security context it shall verify the TAU Request message. If it is successful, the UE and the MME share a current EPS NAS security context. In case the TAU Request had the active flag set or there is pending downlink UP data, K_{eNB} is calculated as described in clause 7.2.7.

If the MME wants to change the algorithms, the MME shall use a NAS security mode procedure (see clause 7.2.4.4).

If the MME does not have the EPS NAS security context indicated by the eKSI by the UE in the TAU request, or the TAU request was received unprotected, the MME shall create a new mapped EPS NAS security context (that shall become the current EPS NAS security context). In this case, the MME shall generate a 32bit NONCE_{MME} (see clause A.10 for requirements on the randomness of NONCE_{MME}) and use the received NONCE_{UE} with the NONCE_{MME} to generate a fresh mapped K'_{ASME} from CK and IK, where CK, IK were identified by the KSI and P-TMSI in the TAU Request. See Annex A.11 for more information on how to derive the fresh K'_{ASME}. The MME initiates a NAS Security mode command procedure with the UE as described in clause 7.2.4.4 including the KSI_{SGSN}, NONCE_{UE}, and NONCE_{MME} in the NAS Security mode command. The uplink and downlink NAS COUNT for mapped EPS NAS security context shall be set to start value (i.e., 0) when new mapped EPS NAS security context is created in UE and MME.

If the TAU Request had the active flag set or there is pending downlink UP data, the uplink NAS Count which is set to zero shall be used to derive the K_{eNB} in MME and UE as specified in Annex A. MME shall deliver the K_{eNB} to the target eNB on the S1 interface.

The TAU Accept shall be protected using the current EPS NAS security context.

9.2 Handover

9.2.1 From E-UTRAN to UTRAN

NAS and AS security shall always be activated before handover from E-UTRAN to UTRAN can take place. Consequently the source system in the handover shall always send a key set to the target system during handover. The security policy of the target PLMN determines the selected algorithms to be used within the UTRAN HO command.

The MME shall select the current NAS downlink COUNT value to use in the handover and then increase the stored NAS downlink COUNT value by 1.

NOTE 0: Increasing the NAS downlink COUNT by 1 is to ensure that a fresh NAS downlink COUNT is used for any future purposes.

UE and MME shall derive a confidentiality key CK', and an integrity key IK' from the K_{ASME} and the selected NAS downlink COUNT value of the current EPS key security context with the help of a one-way key derivation function KDF as specified in Annex A.

Whether UTRAN PS key ciphering is considered active in the target UTRAN after handover from E-UTRAN shall be determined according to the principles for handover to UTRAN in TS 25.331 [24].

UE and MME shall assign the value of eKSI to KSI. MME shall transfer CK' \parallel IK' with KSI to SGSN. The target SGSN shall replace all stored parameters CK, IK, KSI, if any, with CK', IK', KSI received from the MME. The UE shall replace all stored parameters CK, IK, KSI, if any, with CK', IK', KSI in both ME and USIM. START_{PS} shall comply with the rules in 3GPP TS 25.331 [24]. For the definition of the Key Derivation Function see Annex A. The ME shall use CK" and IK" to derive the GPRS Kc using the c3 function specified in 3GPP TS 33.102 [4]. The ME shall assign the eKSI value (associated with CK" and IK") to the GPRS CKSN. The ME shall update the USIM and ME with the GPRS Kc and GPRS CKSN.

- NOTE 1: The new mapped UMTS security context (including CK", and IK") replacing the stored values in the USIM and ME, is for allowing to reuse the mapped UMTS security context without invoking the authentication procedure in subsequent connection set-ups, and also for avoiding that one KSI value gets associated with two different key sets and consequently leads to UMTS security context desynchronization.
- NOTE 2: An operator concerned about the security of keys received from an E-UTRAN of another operator may want to enforce a policy in SGSN to run a UMTS AKA as soon as possible after the handover. One example of ensuring this is the deletion of the mapped UMTS security context in the SGSN after the UE has left active state in UMTS.
- NOTE 3: Due to replacing all the UTRAN PS key parameters CK, IK, KSI with CK", IK" and eKSI on USIM and in ME, a new GPRS Kc needs to be derived from the new UTRAN PS key parameters CK and IK (i.e. CK" and IK"), which is part of the new UMTS security context as well, as any old GPRS Kc stored on USIM and in ME, belongs to an old UMTS security context and can no longer be taken into use.

After HO from E-UTRAN to UTRAN the current EPS NAS security context shall (if it is kept) be considered as the current one in E-UTRAN in the UE and the MME.

MME shall also provide at least the 4 LSB of the selected NAS downlink COUNT value to the source eNB, which then shall include the bits in the MobilityFromE-UTRANCommand to the UE. The UE shall use the received 4 LSB and its stored NAS downlink COUNT to estimate the NAS downlink COUNT selected by the MME.

NOTE 4: It is left to the implementation how to estimate the NAS downlink COUNT.

The UE shall ensure that the estimated NAS downlink COUNT has not been used to calculate a CK' and IK' in a previous successful or unsuccessful PS or SRVCC handover. If the estimated NAS downlink COUNT is greater than all the estimated NAS downlink COUNTs either used by the UE for key derivation in a handover or received in a NAS message that passed its integrity check, the UE shall update its stored NAS downlink COUNT as though it has successfully integrity checked a NAS message with that estimated NAS downlink COUNT. In particular, the stored NAS downlink COUNT shall never be decreased.

MME shall transfer the UE security capabilities to the SGSN. The selection of the algorithms in the target system proceeds as described in TS 33.102 [4] for UTRAN.

If the handover is not completed successfully, the new mapped UMTS security context can not be used in the future. The SGSN shall delete the new mapped UMTS security context and the stored UMTS security context which has the same KSI as the new mapped UMTS security context.

9.2.2 From UTRAN to E-UTRAN

9.2.2.1 Procedure

The procedure for handover from UTRAN to E-UTRAN, as far as relevant for security, proceeds in the following two consecutive steps:

A) Handover signalling using the mapped EPS security context (cf. also Figure 9.2.2.1-1);

B) Subsequent NAS signalling to determine whether a native EPS security context is taken in use (not shown in Figure).

The activation of NAS and AS security in E-UTRAN, and selection of the key set from the source system for the handover shall be according to following principles:

i) As described for inter-SGSN PS handover cases in TS 33.102 [4], the source SGSN shall select the key set most recently generated (either by a successful UMTS AKA run in UTRAN (which may or may not yet have been taken into use by the UE and SGSN) or a UMTS security context mapped from an EPS security context during a previous visit to UTRAN) and transfer this key set to the MME in the Forward Relocation Request.

NOTE 0: The MME is considered as a target SGSN in case of Gn/Gp interface.

ii) Activation of AS security (for details cf. TS 36.331 [21]):

The E-UTRAN HO command received at the UE shall activate AS security.

The HO Complete received at the eNB shall activate AS security.

iii) Activation of NAS security (for details cf. TS 24.301 [9]):

The E-UTRAN HO command received at the UE shall activate NAS security.

The HO Notify received at the MME shall activate NAS security. In case the MME does not have the UE security capabilities stored from a previous visit, then no NAS message shall be sent or accepted by the MME other than a TAU request before a successful check of the UE security capabilities in the TAU request was performed by the MME.

iv) Both AS and NAS ciphering and integrity protection algorithms shall be selected according to the policy of the target PLMN.

The above four principles consequentially always activate ciphering (potentially NULL ciphering) in E-UTRAN even if it was not active in the source system.

Figure 9.2.2.1-1: Handover from UTRAN to E-UTRAN

A) Handover signalling in case of successful handover

Before attempting a handover for a UE, the source RNC may check if the UE is authenticated using UMTS AKA. If the UE is not authenticated using UMTS AKA and the UE does not have an ongoing emergency call, then the source RNC may decide not to perform a handover to E-UTRAN (to avoid triggering unnecessary handover attempts to E-UTRAN which will be rejected by the target MME). The check can be performed by analysing the active CK and IK as follows:

- If the 64 most significant bits of the CK are not identical to the 64 least significant bits of the CK, the RNC can deduce that the UE was authenticated via UMTS AKA. (The bits are identical if the CK is derived from a Kc via the c4 key conversion function [4], and it is very unlikely that they are equal for a CK derived from UMTS AKA.)
- If the 64 most significant bits of the CK are identical to the 64 list significant bits of the CK, the RNC can further check if the IK fulfils the equation given by the c5 key conversion function [4]. If the IK does not fulfil this equation, the RNC can deduce that the UE was authenticated with UMTS AKA, and if the IK does, then the RNC can deduce that the UE was authenticated using GSM AKA.

If the source RNC does not conclude that the UE is authenticated using UMTS AKA, the source RNC may select an appropriate network for the UE at the handover decision stage and may send a Relocation Request message to the SGSN. This message does not contain any security-relevant parameters.

 The SGSN shall transfer MM context (including CK and IK (or the Kc), KSI and the UE security capabilities) to MME in the Forward relocation request message. In case the MM context in the Forward relocation request message indicates GSM security mode(i.e., it contains a Kc), the MME shall abort the non-emergency call procedure. The UE security capabilities, including the UE EPS security capabilities, were sent by the UE to the SGSN via the UE Network Capability IE, in Attach Request and RAU Request. It is possible that an SGSN does not forward the UE EPS security capabilities to the MME. When the MME does not receive UE EPS security capabilities from the SGSN, the MME shall assume that the following default set of EPS security algorithms is supported by the UE (and shall set the UE EPS security capabilities in the mapped EPS NAS security context according to this default set):

- a. EEA0, 128-EEA1 and 128-EEA2 for NAS signalling ciphering, RRC signalling ciphering and UP ciphering;
- b. 128-EIA1 and 128-EIA2 for NAS signalling integrity protection and RRC signalling integrity protection.
- NOTE 1: Subclauses 5.1.3.2 and 5.1.4.2 of this specification mandate the UE to support the default set of EPS security algorithms, so, for the Rel-8 version of this specification, the default set of EPS security algorithms includes all security algorithms standardised for EPS. The notion of default set of EPS security algorithms is introduced here in order to make this specification future-proof as more security algorithms may be standardised for EPS in future releases.
- NOTE 1a: If the UE has an unauthenticated IMS Emergency Service without integrity protection ongoing before the IRAT handover to LTE, the SGSN must be Rel-9 + and thus be able to forward the UE EPS security capabilities including EIA0 to the MME. In this case the MME would select EIA0 algorithm.
- 2. The MME shall create a NONCE_{MME} to be used in the K'_{ASME} derivation (see clause A.10 for requirements on the randomness of NONCE_{MME}). MME shall derive K'_{ASME} from CK and IK with the help of a one-way key derivation function as defined in Annex A and associate it with a Key Set Identifier KSI_{SGSN}. The value field of the KSI_{SGSN} shall be derived by assigning the KSI corresponding to the set of keys most recently generated (either by a successful UMTS AKA run in UTRAN (which may or may not yet have been taken into use by the UE and the SGSN) or a UMTS security context mapped from an EPS security context during a previous visit in UTRAN). MME shall derive the NAS keys and K_{eNB} from K'_{ASME}. The uplink and downlink NAS COUNT values for the mapped EPS security context shall be set to start value (i.e. 0) in the UE and the MME.
- 3. MME shall select the NAS security algorithms (including ciphering and integrity protection) which have the highest priority from its configured list and are also present in the UE EPS security capabilities, MME shall include KSI_{SGSN}, NONCE_{MME}, the selected NAS security algorithms in the NAS Security Transparent Container IE of S1 HO Request message to the target eNB. MME further shall include K_{eNB} and the UE EPS security capabilities, either the capabilities received from the SGSN or, in the absence of these, the default set of EPS security algorithms, in the S1 HO Request message to the target eNB.
- 4. The target eNB shall select the AS algorithms (including ciphering for both RRC and UP, and integrity protection for RRC) which have the highest priority from its configured list and is also present in the UE EPS security capabilities. The target eNB shall create a transparent container (RRCConnectionReconfiguration) including the selected RRC, UP algorithms and the NAS Security Transparent Container IE, and send it in the S1 HO Request Ack message towards the MME.

NOTE 2: This transparent container is not protected by the target eNB.

- 5. MME shall include the transparent container received from the target eNB in the FW Relocation Response message sent to SGSN.
- 6. SGSN shall include the transparent container in the relocation command sent to the RNC.
- 7. The RNC shall include the transparent container in the UTRAN HO command sent to the UE.

NOTE 3: The UTRAN HO command is integrity protected and optionally ciphered as specified by TS 33.102 [4].

- 8. The UE shall derive K'_{ASME} in the same way the MME did in step 2, associate it with KSI_{SGSN} and derive NAS, RRC and UP keys accordingly. The UE shall send a RRCConnectionReconfiguration Complete messages to the eNB. The uplink and downlink NAS COUNT values for the mapped EPS security context shall be set to start value (i.e. 0) in the UE and the MME.
- 9. The mapped EPS security context shall become the current (cf. subclause 3.1) EPS security context at AS and NAS level and overwrite any existing current mapped EPS security context. If the current EPS security context is of type native, then it shall become the non-current native EPS security context and overwrite any existing non-current EPS security context. The HO Complete messages and all following AS messages in E-UTRAN shall be ciphered and integrity protected according to the policy of the target PLMN.

If the handover is not completed successfully, the new mapped EPS security context can not be used in the future. The MME shall delete the new mapped EPS security context.

B) Subsequent NAS signalling

In order to prevent that successful bidding down on the UE security capabilities in a previous RAT have an effect on the selection of EPS security algorithm for NAS and AS, the UE security capabilities shall be included in the TAU request after IRAT-HO and be verified by the MME.

NOTE 4: Any TAU request following the handover will be integrity protected. Details are described in subclause 9.2.2.1

In any case UE security capability information received from the UE overwrites any capabilities received with the context transfer as specified in TS 23.401 [2].

It can happen that the MME receives different UE EPS security capabilities in the TAU Request from the already stored UE EPS security capabilities in MME (received from the source SGSN or the default UE EPS security capabilities when MME uses the default set of EPS security algorithms for the UE according to A) step 1 above). If it happens, the MME shall perform as follows:

- In case the TAU Request contains a higher priority NAS algorithm (according to the priority list stored in the MME), the MME run a NAS security mode command procedure to change the NAS algorithms according to subclause 7.2.4.4.
- MME shall send an S1 CONTEXT MODIFICATION REQUEST message to inform the eNB about the correct UE EPS security capabilities.

The eNB shall trigger a change of AS algorithms if the received UE EPS security capabilities from the S1 CONTEXT MODIFICATION REQUEST message would contain higher priority AS algorithm (according to the priority list stored in the eNB).

- 1. If the MME has native security context for the UE and does not receive a TAU request within a certain period after the HO it shall assume that UE and MME share a native security context.
- NOTE 5: A TAU procedure following handover from UTRAN to E-UTRAN is mandatory if the Tracking Area has changed, but optional otherwise, cf. TS 23.401[2].
- 2. When the UE sends a TAU request it shall protect the request using the mapped EPS security context identified by KSI_{SGSN}. The UE shall also include KSI_{ASME} in the TAU request if and only if it has native EPS security context. The KSI_{ASME} shall be accompanied by a GUTI. When the MME receives a TAU request with a KSI_{ASME} and GUTI corresponding to the non-current native EPS security context stored on that MME it knows that UE and MME share a non-current native EPS security context.
- 3. Void.
- 4. When the MME receives a TAU request without a KSI_{ASME} it shall delete any non-current native EPS security context for any GUTI it may have for the user who sent the TAU request.
- 5. If the MME shares the non-current native EPS security context indexed by the KSI_{ASME} and GUTI from the TAU Request with the UE, the MME may run a NAS security mode command procedure with the UE to activate the non-current native EPS NAS security context according to clause 7.2.9.4. The MME may in addition change the K_{eNB} on the fly according to clause 7.2.9.2. In case the GUTI received in the TAU Request message pointed to a different MME, the allocation of a new GUTI, replacing the received GUTI, and the association of this new GUTI with KSI_{ASME} is required.
- 6. Void.
- NOTE 6: The TAU Request is integrity protected with the mapped EPS security context even if the UE and the MME share a non-current native EPS security context since the UE cannot know for sure if the MME still has the non-current native EPS security context at the time of sending the TAU Request.
- 7. When the MME knows, after having completed the TAU procedure in the preceding steps, that it shares a noncurrent native EPS security context with the UE, the MME may (depending on configured policy and if the MME did not do it already in step 5) activate this non-current native EPS security context. This activation may occur in three ways:
 - a. When the UE has cryptographically protected radio bearers established: the MME shall initiate a key change on the fly procedure according to subclause 7.2.9 for the entire EPS key hierarchy.

- b. After the next transition to ECM-IDLE state following the handover from UTRAN: Upon receiving the first message from the UE after the UE has gone to ECM-IDLE state the MME shall use the procedures defined in subclauses 7.2.4.4 and 7.2.4.5 to activate the non-current native EPS security context if such exists.
- c. At the next transition to EMM-DEREGISTERED (see clause 7.2.5.1).
- 8. If a non-current native EPS security context has been established, then the UE and the MME shall delete the mapped EPS security context and set the non-cur rent native EPS security context to the current EPS security context.
- NOTE 7: The run of a NAS SMC procedure ensures that the uplink NAS COUNT has increased since the last time a K_{eNB} was derived from the K_{ASME} .
- NOTE 8: For the handling of native and mapped EPS NAS security contexts after a state transition to EMM-DEREGISTERED cf. subclause 7.2.5.1.

9.2.2.2 Derivation of NAS keys and K_{eNB} during Handover from UTRAN to E-UTRAN

MME and UE shall derive the NAS keys from the mapped key K'_{ASME} as specified in Annex A.

The MME and UE shall derive K_{eNB} by applying the KDF defined in Annex A.3 ED transition using the mapped key K'_{ASME} and 2^{32} -1 as the value of the uplink NAS COUNT parameter.

NOTE: The MME and UE only uses the 2^{32} -1 as the value of the uplink NAS COUNT for the purpose of deriving K_{eNB} and do not actually set the uplink NAS COUNT to 2^{32} -1. The reason for choosing such a value not in the normal NAS COUNT range, i.e., $[0, 2^{24}-1]$ is to avoid any possibility that the value may be used to derive the same K_{eNB} again.

9.3 Recommendations on AKA at IRAT-mobility to E-UTRAN

After a handover from GERAN or UTRAN into E-UTRAN, it is strongly recommended to run an AKA and perform a key change on-the-fly of the entire key hierarchy as soon as possible after the handover if there is no native security context in E-UTRAN.

When a UE moves in IDLE mode from GERAN or UTRAN into E-UTRAN, it is strongly recommended to run an AKA if there is no native security context in E-UTRAN, either after the TAU procedure that establishes an EPS security context in the MME and UE, or when the UE establishes cryptographically protected radio bearers.

9.4 Attach procedures

9.4.1 Attach in UTRAN

This subclause covers ths case that the UE include a mapped GUTI into the 'old P-TMSI' Information Element of the Attach Request.

NOTE 1: TS 23.060 states conditions under which a valid P-TMSI or a P-TMSI that is mapped from a valid GUTI ('mapped GUTI') is inserted in the Information Element 'old P-TMSI' in the Attach Request.

If the UE has a current EPS NAS security context, it shall include a truncated NAS-token, as defined in subclause 9.1.1, into the P-TMSI signature IE of the Attach Request. It shall also include the KSI equal to the value of the eKSI associated with the current EPS security context.

If the UE does not have a current EPS NAS security context, the UE shall set the truncated NAS-token to all zero and the KSI to "111" to indicate the UE has no keys available.

The SGSN shall forward the P-TMSI signature including the truncated NAS-token to the old MME. The MME may check a non-zero NAS-token as described in subclause 9.1.1. If successful, the MME responds with an Identification Response to the SGSN. If unsuccessful the MME responds with an appropriate error cause which should initiate the security functions in the SGSN.

If P-TMSI Signature includes an all zero NAS-token or the MME chooses not to check the NAS-token, the MME may respond with an Identification Request that does not include keys.

If needed, the MME and UE shall derive CK' and IK' from the K_{ASME} as in subclause 9.1.1. Keys CK' and IK' and KSI sent from the MME shall replace all the UTRAN PS key parameters CK, IK and KSI in the target SGSN if any. Keys CK' and IK' and the KSI shall replace all the currently stored UTRAN PS key parameters CK, IK, KSI values on both the USIM and ME. The handling of START_{PS} shall comply with the rules in 3GPP TS 25.331 [24]. The UE may set the START_{PS} value to 0 if it is done before establishment of the RRC connection.

The ME shall use CK" and IK" to derive the GPRS Kc using the c3 function specified in 3GPP TS 33.102 [4]. The ME shall assign the eKSI value (associated with CK" and IK") to the GPRS CKSN. The ME shall update the USIM and ME with the GPRS Kc and GPRS CKSN.

NOTE 2: Due to replacing all the UTRAN PS key parameters CK, IK, KSI with CK", IK" and eKSI on USIM and in ME, a new GPRS Kc needs to be derived from the new UTRAN PS key parameters CK and IK (i.e. CK" and IK"), which is part of the new UMTS security context as well, as any old GPRS Kc stored on USIM and in ME, belongs to an old UMTS security context and can no longer be taken into use.

10 Security interworking between E-UTRAN and GERAN

10.1 General

An SGSN supporting interworking between E-UTRAN and GERAN is capable of handling UMTS security contexts and supports the key conversion function c3 specified in TS 33.102 [4]. Such a SGSN is, according to TS 33.102, required to ensure that the UE is authenticated using UMTS AKA, if the UE supports UMTS AKA. Furthermore, the UE must have a USIM to be able to access EPS, except for unauthenticated emergency calls if allowed by regulations. Hence, UMTS AKA is used when the UE is authenticated to the SGSN supporting interworking between E-UTRAN and GERAN even when attached to GERAN, and UMTS security contexts are available. The security procedures for interworking between E-UTRAN and GERAN are therefore quite similar to those between E-UTRAN and UTRAN.

10.2 RAU and TAU procedures

10.2.1 RAU procedures in GERAN

This subclause covers both the cases of idle mode mobility from E-UTRAN to GERAN and of Idle Mode Signaling Reduction, as defined in TS 23.401 [2].

As the target SGSN and UE are capable of handling UMTS security contexts clause 9.1.1 applies here with the following changes

- the target SGSN shall derive GPRS cipher key Kc from CK" and IK" with the help of the key conversion function c3 defined by TS 33.102 [4], and the target SGSN and UE shall derive GPRS Kc_{128} as defined by TS 33.102 [4] from CK' and IK' when the new encryption algorithm selected by the target SGSN requires Kc_{128} ; the target SGSN and UE shall assign the eKSI value (associated with the CK" and IK") to the GPRS CKSN associated with the GPRS Kc_{128} .
- the target SGSN shall select the encryption algorithm to use in GERAN.

10.2.2 TAU procedures in E-UTRAN

This subclause covers both the cases of idle mode mobility from GERAN to E-UTRAN and of Idle Mode Signaling Reduction, as defined in TS 23.401 [2].

As the SGSN shares a UMTS security context with the UE clause 9.1.2 applies here without changes.

10.3 Handover

10.3.1 From E-UTRAN to GERAN

As the target SGSN and the UE are capable of handling UMTS security contexts clause 9. 2.1 applies here with the following changes:

- the target SGSN shall derive GPRS cipher key Kc from CK' and IK' with the help of the key conversion function c3 as defined by TS 33.102 [4], and target SGSN and UE shall derive GPRS Kc_{128} as defined by TS 33.102 [4] from CK' and IK' when the new encryption algorithm selected by the target SGSN requires Kc_{128} . The target SGSN and UE shall assign the eKSI value (associated with the CK" and IK") to the GPRS CKSN associated with the GPRS Kc_{128} .
- the target SGSN shall select the encryption algorithm to use in GERAN after handover.
- Whether ciphering is considered active in the target GERAN after handover from E-UTRAN shall be determined according to the principles for handover to GERAN in TS 44.060 [25].

10.3.2 From GERAN to E-UTRAN

10.3.2.1 Procedures

As the SGSN shares a UMTS security context with the UE clause 9.2.2 applies here without changes.

10.4 Recommendations on AKA at IRAT-mobility to E-UTRAN

See recommendation provided by subclause 9.3.

10.5 Attach procedures

10.5.1 Attach in GERAN

As the SGSN is capable of handling UMTS security contexts clause 9.1.1 applies here with the following changes

- the SGSN and UE shall derive GSM cipher key Kc as defined by TS 33.102 [4] from CK' and IK', and the SGSN and UE shall derive Kc₁₂₈ as defined by TS 33.102 [4] from CK' and IK' when the new encryption algorithm selected by the target SGSN requires Kc₁₂₈;
- SGSN shall select the encryption algorithm to use in GERAN.

11 Network Domain Control Plane protection

The protection of IP based control plane signalling for EPS and E-UTRAN shall be done according to TS 33.210 [5].

In order to protect the S1 and X2 control plane, it is required to implement IPsec ESP according to RFC 4303 [7] as specified by TS 33.210 [5]. For both S1-MME and X2-C, IKEv2 certificates based authentication according to TS 33.310 [6] shall be implemented. For S1-MME and X2-C, tunnel mode IPsec is mandatory to implement on the eNB. On the core network side a SEG may be used to terminate the IPsec tunnel.

NOTE 1: In case control plane interfaces are trusted (e.g. physically protected), there is no need to use protection according to TS 33.210 [5] and TS 33.310 [6].

Transport mode IPsec is optional for implementation on the X2-C and S1-MME.

NOTE 2: Transport mode can be used for reducing the protocol overhead added by IPsec.

Other 3GPP specifications may specify other IKEv2 and certificate profiles and IPsec implementation details for specific types of eNBs. The provisions in such other 3GPP specifications shall take precedence over the provisions in the present clause for those specific eNB types only if explicitly listed here. In particular, the provisions for HeNBs specified in TS 33.320 [27] shall take precedence over the provisions in this clause.

12 Backhaul link user plane protection

The protection of user plane data between the eNB and the UE by user specific security associations is covered by clause 5.1.3 and 5.1.4.

In order to protect the S1 and X2 user plane as required by clause 5.3.4, it is required to implement IPsec ESP according to RFC 4303 [7] as profiled by TS 33.210 [5], with confidentiality, integrity and replay protection.

On the X2-U and S1-U, transport mode IPsec is optional for implementation.

NOTE 1: Transport mode can be used for reducing the protocol overhead added by IPsec.

Tunnel mode IPsec is mandatory to implement on the eNB for X2-U and S1-U. On the core network side a SEG may be used to terminate the IPsec tunnel.

For both S1 and X2 user plane, IKEv2 with certificates based authentication shall be implemented. The certificates shall be implemented according to the profile described by TS 33.310 [6]. IKEv2 shall be implemented conforming to the IKEv2 profile described in TS 33.310 [6]. Other 3GPP specifications may specify other IKEv2 and certificate profiles and IPsec implementation details for specific types of eNBs. The provisions in such other 3GPP specifications shall take precedence over the provisions in the present clause for those specific eNB types only if explicitly listed here. In particular, the provisions for HeNBs specified in TS 33.320 [27] shall take precedence over the provisions in this clause.

NOTE 2: In case S1 and X2 user plane interfaces are trusted (e.g. physically protected), the use of IPsec/IKEv2 based protection is not needed.

13 Management plane protection over the S1 interface

Clause 5.3.2 requires that eNB setup and configuration traffic, i.e. the management plane, to be protected between the EPS core and the eNB. This traffic is typically carried over the same backhaul link as the S1 interface. Therefore, the protection mechanism defined for S1-MME and S1-U may be re-used for S1 management plane, S1-M.

In this case and in order to achieve such protection, it is required to implement IPsec ESP according to RFC 4303 [7] as profiled by TS 33.210 [5], with confidentiality, integrity and replay protection.

Tunnel mode IPsec is mandatory to implement on the eNB for supporting the S1 management plane. On the core network side a SEG may be used to terminate the IPsec tunnel. If no SEG is used, the IPsec tunnel may be terminated in the element manager.

For the S1 management plane, IKEv2 with certificates based authentication shall be implemented on the eNB. The certificates shall be implemented according to the profile described by TS 33.310 [6]. IKEv2 shall be implemented conforming to the IKEv2 profile described in TS 33.310 [6]. Other 3GPP specifications may specify other IKEv2 and certificate profiles and IPsec implementation details for specific types of eNBs.

Other 3GPP specifications may specify other security mechanisms and certificate profiles for specific types of eNBs for the case when the management traffic is not carried over the same backhaul link as S1 traffic. If other security mechanisms are specified, they shall provide mutual authentication based on certificates, as well as confidentiality, integrity and replay protection. These functions shall have at least equal strength as that provided by the use of IKEv2/IPsec.

The provisions in such other 3GPP specifications shall take precedence over the provisions in the present clause for those specific eNB types only if explicitly listed here. In particular, the provisions for HeNBs specified in TS 33.320 [27] shall take precedence over the provisions in this clause.

NOTE 1: X2 does not carry management plane traffic.

NOTE 2: In case the S1 management plane interfaces are trusted (e.g. physically protected), the use of protection based on IPsec/IKEv2 or equivalent mechanisms is not needed

14 SRVCC between E-UTRAN and Circuit Switched UTRAN/GERAN

14.1 From E-UTRAN to Circuit Switched UTRAN/GERAN

Single Radio Voice Call Continuity (SRVCC) is specified in 3GPP TS 23.216 [22].

The MME shall select the current NAS downlink COUNT value to use in the handover and then increase the stored NAS downlink COUNT value by 1.

NOTE 0: Increasing the NAS downlink COUNT by 1 is to ensure that a fresh NAS downlink COUNT is used for any future purposes.

The MME and the UE shall derive a confidentiality key CK_{SRVCC} , and an integrity key IK_{SRVCC} from K_{ASME} of the current EPS security context and the selected NAS downlink COUNT with the help of a one-way key derivation function KDF as specified in Annex A.

The KDF returns a 256-bit output, where the 128 most significant bits are identified with CK_{SRVCC} and the 128 least significant bits are identified with IK_{SRVCC} .

The MME shall also provide the 4 LSB of the selected NAS downlink COUNT value to the source eNB, which then includes the bits to the HO Command to the UE. The UE shall use the received 4 LSB and its stored NAS downlink COUNT to estimate the NAS downlink COUNT selected by the MME.

NOTE 1: It is left to the implementation how to estimate the NAS downlink COUNT.

The UE shall ensure that the estimated NAS downlink COUNT has not been used to calculate a CK' and IK' in a previous successful or unsuccessful PS or SRVCC handover. If the estimated NAS downlink COUNT is greater than all the estimated NAS downlink COUNTs either used by the UE for key derivation in a handover or received in a NAS message that passed its integrity check, the UE shall update its stored NAS downlink COUNT as though it has successfully integrity checked a NAS message with that estimated NAS downlink COUNT. In particular, the stored NAS downlink COUNT shall never be decreased.

UE and MME shall assign the value of eKSI to KSI. MME shall transfer CK_{SRVCC} , IK_{SRVCC} with KSI and the UE security capability to the MSC server enhanced for SRVCC. The MSC server enhanced for SRVCC shall replace all the stored UTRAN CS key parameters CK, IK, KSI, if any, with CK_{SRVCC} , IK_{SRVCC} , KSI received from the MME when the SRVCC handover is successful. The UE shall replace all the stored UTRAN CS key parameters CK, IK, KSI, if any, with CK_{SRVCC} , IK_{SRVCC} , IK_{SRVCC} , IK, KSI, if any, with CK_{SRVCC} , IK_{SRVCC} ,

The ME shall use CK_{SRVCC} and IK_{SRVCC} to derive the GSM CS Kc using the c3 function specified in 3GPP TS 33.102 [4]. The ME shall assign the eKSI value (associated with CK_{SRVCC} and IK_{SRVCC}) to the GSM CS CKSN (associated with the GSM CS Kc). The ME shall update the USIM and ME with the GSM CS Kc and GSM CS CKSN.

- NOTE 2: The new derived security context (including CK_{SRVCC}, IK_{SRVCC}, and KSI) replacing the stored values in the USIM is for allowing to reuse the derived security context without invoking the authentication procedure in subsequent connection set-ups, and also for avoiding that one KSI value indicates to two different key sets and consequently leads to security context desynchronization.
- NOTE 3: An operator concerned about the security of keys received from an E-UTRAN of another operator may want to enforce a policy in the MSC server enhanced for SRVCC to run a UMTS AKA as soon as possible after the handover. One example of ensuring this is the deletion of the mapped UMTS security context in the enhanced MSC server after the UE has left active state.
- NOTE 4: Due to replacing all the UTRAN CS key parameters CK, IK, KSI with CK_{SRVCC}, IK_{SRVCC} and KSI on USIM and in ME, a new GSM CS Kc needs to be derived from the new UTRAN CS key parameters CK and IK (i.e. CK_{SRVCC} and IK_{SRVCC}), which is part of the new UMTS security context as well, as any old GSM CS Kc stored on USIM and in ME, belongs to an old UMTS security context and can no longer be taken into use.

If the SRVCC is from E-UTRAN to GERAN, the above description in this section applies as well for the MME, the enhanced MSC server and the UE. The enhanced MSC server shall in addition derive GSM CS cipher key Kc from CK_{SRVCC} and IK_{SRVCC} with the help of the key conversion function c3 as specified in TS 33.102 [4], and assign the value of eKSI to GSM CS CKSN associated with the GSM CS Kc, and the target MSC server and UE shall compute the 128-bit GSM CS cipher key Kc₁₂₈ as specified in TS 33.102 [4] when the new encryption algorithm selected by the target BSS requires Kc₁₂₈. The UE and the enhanced MSC Server shall assign the value of eKSI to GSM CS CKSN associated with the GSM CS Server shall assign the value of eKSI to GSM CS CKSN associated with the GSM CS Server shall assign the value of eKSI to GSM CS CKSN associated with the GSM CS Server shall assign the value of eKSI to GSM CS CKSN associated with the GSM CS Server shall assign the value of eKSI to GSM CS CKSN associated with the GSM CS Kc₁₂₈.

NOTE 5: Non-voice bearers may be handed over during the SRVCC handover operation. Key derivation for nonvoice bearers is specified in clause 9 of the present specification.

If the SRVCC handover is not completed successfully, the new mapped CK_{SRVCC} , IK_{SRVCC} and KSI_{SRVCC} can not be used in the future. The MSC server enhanced for SRVCC shall delete the new mapped CK_{SRVCC} , IK_{SRVCC} and KSI_{SRVCC} and the stored parameters CK_{CS} and IK_{CS} which has the same KSI as the new mapped CK_{SRVCC} , IK_{SRVCC} (if such exist).

14.2 Emergency call in SRVCC

If the SRVCC is for an emergency call and the session in EUTRAN complies with clause 15.2.1, the security procedure in clause 14.1 shall be applied.

If the SRVCC is for an emergency call and the session in EUTRAN complies with clause 15.2.2, the security procedure in clause 14.1 shall not be applied, i.e., no key derivation is needed.

15 Security Aspects of IMS Emergency Session Handling

15.1 General

Support for IMS Emergency Sessions is defined in the TS 23.401 [2]. Limited service state of a UE is defined in TS 23.122 [26]. IMS Emergency Sessions can be made by normally attached UEs or UEs attached for EPS emergency bearer services. IMS Emergency Services can be authenticated or unauthenticated as defined in clauses below. It depends on the serving network policy if unauthenticated IMS Emergency Sessions are allowed. Any behaviour not explicitly specified as being special to IMS Emergency Sessions is handled in accordance to normal procedures.

The E-UTRAN Initial Attach procedure, with Attach Type "Emergency", is used by UEs that need to receive EPS emergency bearer services but cannot receive normal services from the network.

For an Initial Attach with Attach Type "Emergency" the UE includes the IMSI in the Attach request if the UE does not have a valid GUTI. The UE shall include the IMEI when the UE has no IMSI, no valid GUTI according to [2].

When involved in an Attach for EPS emergency bearer services the MME applies the parameters from MME Emergency Configuration Data for the EPS emergency bearer establishment. Any potentially stored IMSI related subscription data is ignored by the MME according to [2].

When involved in an Attach for EPS emergency bearer services the MME does not send any Notify Request to an HSS.

A UE attached for EPS emergency bearer services using NULL algorithms shall keep the NULL algorithms and corresponding NAS COUNTs when in EMM-IDLE mode so that it is reachable for subsequent IMS Emergency Sessions without the need to attach for EPS emergency bearer services again. The NULL algorithms shall be deselected and corresponding NAS COUNTs shall be removed when the UE goes to EMM-DEREGISTERED state or when another EPS NAS security context is activated.

The MME or UE shall always release any established non-emergency bearers, when the authentication fails in the UE or in the MME.

15.2 Security procedures and their applicability

15.2.1 Authenticated IMS Emergency Sessions

15.2.1.1 General

UEs that are not in limited service state, shall initiate normal initial attach when not already attached to receive EPS emergency bearer services.

The security mode control procedure shall be applied as part of EPS emergency bearer establishment as defined in TS 23.401 [2]. Thus, integrity protection (and optionally ciphering) shall be applied as for normal EPS bearers. If authentication fails for any reason, the handling of the EPS emergency bearer services shall be handled as specified in clauses 15.2.1 and 15.2.2 below. Once the IMS Emergency Session is in progress with NAS and AS integrity protection (and optionally ciphering) applied, failure of integrity checking or ciphering (for both NAS and AS) is an unusual circumstance and shall be treated as in the case of a normal EPS bearer.

15.2.1.2 UE and MME share a current security context

If the UE already has a current EPS security context and attempts to set up an IMS Emergency Session, the UE shall use this EPS security context to protect NAS, RRC and UP traffic. If the MME successfully validates a request for EPS emergency bearer services using the current EPS security context, the MME should accept this request. A request for EPS emergency bearer services is defined to be, for the purposes of this document, an Attach request message for EPS emergency bearer services or a PDN Connectivity request message for EPS emergency bearer services.

ETSI

3GPP TS 33.401 version 9.8.0 Release 9

NOTE 1: It is defined in TS 23.401 [2] and TS 24.301 [9] how Attach requests and/or PDN Connectivity requests are used to set up EPS emergency bearer services.

If the authentication fails during a normal Attach procedure, or a Service request procedure, while the UE is in normal service mode, and the UE intends to set up an IMS Emergency Session, the UE shall retry by sending an Attach request for EPS emergency bearer services.

If the MME attempts to authenticate the UE after receiving a request for EPS emergency bearer services which was integrity protected by the current EPS NAS security context and the authentication failed and if the serving network policy does not allow unauthenticated IMS Emergency Sessions, the UE and MME shall proceed as for set up of normal EPS bearers as described in clause 6.1.1.

If the MME attempts to authenticate the UE after receiving a request for EPS emergency bearer services which was integrity protected by the current EPS NAS security context and the authentication failed and the serving network policy allows unauthenticated IMS Emergency Sessions, then the UE and the MME behaviours are described in the paragraph below.

If the authentication failure is detected in the UE or in the MME during an attach procedure for EPS emergency bearer services or a PDN connectivity request procedure for EPS emergency bearer services, and the related signalling messages were correctly integrity-protected by the current EPS security context, the set up of the EPS emergency bearers shall then proceed in one of two ways:

- a) The set-up proceeds according to clause 15.2.2. In this case, there is no need for the UE to re-attach, and the MME requests the use of the NULL ciphering and integrity algorithms in the same way as described in clause 15.2.2.2 for the case that UE and MME share no EPS security context.
- NOTE 2: If the authentication failure is detected in the MME then the UE is not aware of the failure in the MME, but still needs to be prepared, according to the conditions specified in TS 24.301, to accept a NAS SMC from the MME requesting the use of the NULL ciphering and integrity algorithms.
- b) Or else, if the serving network policy allows unauthenticated IMS Emergency Sessions and MME continues using the current security context, the use of the EPS emergency bearers may proceed as described below for the case of an AKA run while a PDN connection for emergency bearer services exists.
- NOTE 3: Regardless of if the authentication failed in the UE or in the MME, the MME can assume that the UE will accept that NULL integrity and ciphering algorithms are selected in the security mode control procedure.
- If AKA is run while a PDN connection for emergency bearer services exists, the MME and UE shall behave as follows:

UE behavior:

- Upon successful authentication verification in the UE, the UE shall send RES to the MME.
- NOTE 4: If the authentication failure is detected in the MME, the UE is not aware of the failure in the MME if the MME continues to use the current security context with the UE. The UE consider itself to be in normal service, if it was normal attached before the PDN connectivity request procedure for EPS emergency bearer services was initiated, until the MME releases the non-emergency bearers established with the UE.
- Alternatively, upon authentication verification failure in the UE, the UE shall send an Authentication Failure message to the MME. The UE shall continue using the current EPS security context. If the UE receives a NAS security mode command selecting NULL integrity and ciphering algorithms, the UE shall accept this as long as the IMS Emergency session progresses.

MME behavior:

- If the serving network policy requires IMS Emergency Sessions to be authenticated, the MME shall, after the unsuccessful comparison of RES to XRES, i.e. AKA failure, proceed as if the request for EPS emergency bearers was a request for normal EPS bearer services. The MME should not send an Authentication Reject message if authentication failed in the MME and the serving network policy allows unauthenticated IMS Emergency Sessions. If the MME does not send an Authentication Reject message it shall continue using the current security context with the UE.
- After receiving both, the EC Indication and the Authentication Failure message, the MME shall continue using the current security context with the UE for establishing an EPS emergency bearer.

3GPP TS 33.401 version 9.8.0 Release 9

NOTE : In the case that NAS COUNT values are about to wrap around, and AKA fails, or if the MME is unable to fetch new authentication vectors, the handling of the EPS emergency beares are as described by TS 24.301 [9].

15.2.2 Unauthenticated IMS Emergency Sessions

15.2.2.1 General

Authentication may fail for a UE attached for EPS emergency bearer services just as for a UE attached for normal EPS bearer services when the UE tries to establish an IMS Emergency Session.

As defined in TS 23.401 [2] and as a serving network option, IMS Emergency Sessions may be established in limited service state without the network having to authenticate the UE or apply ciphering or integrity protection for either AS or NAS.

The following are the only identified cases where the "security procedure not applied" option may be used:

- a) Authentication is impossible because the USIM is absent;
- b) Authentication is impossible because the serving network cannot obtain authentication vectors due to a network failure;
- c) Authentication is impossible because the USIM is in limited service mode in the serving network (e.g. there is no roaming agreement or the IMSI is barred, etc.);
- d) Authentication is possible but the serving network cannot successfully authenticate the USIM.

If the ME receives a NAS SMC selecting EIA0 (NULL integrity) for integrity protection, and EEA0 (NULL ciphering) for encryption protection, then:

- the ME shall mark any stored native EPS NAS security context on the USIM /non-volatile ME memory as invalid; and

- the ME shall not update the USIM/non-volatile ME memory with the current EPS NAS security context.

These two rules override all other rules regarding updating the EPS NAS security context on the USIM/non-volatile ME memory, in this specification.

If EIA0 is used, and the NAS COUNT values wrap around, and a new K_{ASME} has not been established before the NAS COUNT wrap around, the NAS connection shall be kept.

NOTE: For unauthenticated emergency calls, EIA0, i.e., null integrity algorithm, is used for integrity protection. Additionally, as the NAS COUNT values are allowed to wrap around, the initialization of the NAS COUNT values are not crucial. Uplink and downlink NAS COUNT are incremented for NAS message that use EIA0, as for any other NAS messages.

Since a UE with a 2G SIM cannot be in authenticated via EPS AKA, it shall be considered by the MME to be unauthenticated in E-UTRAN. A UE with a 2G SIM shall at an IRAT handover to E-UTRAN when an IMS Emergency Service is active, be considered by the MME to be unauthenticated. In such a scenario, EIA0 shall be used in E-UTRAN after handover if the target network policy allows unauthenticated IMS Emergency Sessions.

A handover from E-UTRAN to another RAT, of an unauthenticated IMS Emergency Session, shall result in an unauthenticated IMS Emergency Session or a circuit switched emergency call (depending on if it is a PS handover or SRVCC) in the other RAT.

15.2.2.2 UE and MME share no security context

If the MME attempts to authenticate the UE after receiving the EPS emergency bearer setup request and the authentication failed and if the serving network policy does not allow unauthenticated IMS Emergency Sessions, the UE and MME shall proceed as for normal EPS bearer setup requests as described in clause 6.1.1.

If the UE is not yet authenticated and while the UE is trying to setup an IMS Emergency Session, the authentication failed in the UE, the UE shall wait for a NAS SMC command to set up an unauthenticated emergency bearer. If the serving network policy supports unauthenticated IMS Emergency Sessions, only then the MME shall support

unauthenticated EPS emergency bearer setup. In this case, the behaviours of the UE and the MME are as described below.

The confluence of EPS emergency bearer setup and authentication failure means that the UE is considered by the MME and UE itself to be in LSM even though the UE could have been in normal service mode before the EPS emergency bearer setup.

UE behavior:

After sending EC Indication to the serving network the UE shall know of its own intent to establish an IMS Emergency Session.

- The UE will proceed as specified for the non-emergency case in clauses 6 and 7 of this specification except that the UE shall accept a NAS SMC selecting EEA0 and EIA0 algorithms from the MME.
- NOTE: In case of authentication success the MME will send a NAS SMC selecting algorithms as defined in clause 7 of this specification, i.e. with a non-NULL integrity algorithm, and the UE will accept it.

MME behavior:

After receiving EC Indication from the UE, the MME knows of that UE's intent to establish an IMS Emergency Session.

- If the MME cannot identify the subscriber, or cannot obtain authentication vectors, the MME shall send NAS SMC with NULL algorithms to the UE.

- After the unsuccessful comparison of RES to XRES, i.e. AKA failure, the MME shall send NAS SMC with NULL algorithms to the UE.

- After the receiving of both, the EC Indication and the Authentication Failure messages, the MME shall send NAS SMC with NULL algorithms to the UE.

If the serving network policy does not allow unauthenticated IMS Emergency Sessions, the MME shall reject the unauthenticated EPS emergency bearer setup request from the UE.

15.2.3 Void

15.2.4 Key generation procedures for unauthenticated IMS Emergency Sessions

15.2.4.1 General

An unauthenticated UE does not share a complete EPS NAS security context with the network. Since there has been no successful EPS AKA run, the UE and the MME does not share a K_{ASME} . When the UE and the MME does not share a K_{ASME} the only possibility for an MME that allows unauthenticated IMS Emergency Sessions is to run with the NULL integrity algorithm EIA0 and the NULL ciphering algorithm EEA0. These algorithms are not affected by the choice of key. Therefore the UE and the MME independently generate a K_{ASME} in an implementation defined way and populate the EPS NAS security context with this K_{ASME} to be used when activating an EPS NAS security context for which no successful EPS AKA run has been made. After this EPS NAS security context is activated all key derivations proceed as if they were based on a K_{ASME} generated from an EPS AKA run.

Even if no confidentiality or integrity protection is provided by EIA0 and EEA0, the UE and network treat the EPS security context with the independently generated K_{ASME} as if it contained a normally generated K_{ASME} and hence share an EPS security context (see TS 24.301[9]).

15.2.4.2 Handover

When UE attempts to make X2/S1 handover, UE and eNB derive and transfer the keys as normal to re-use the normal handover mechanism. Since the derived keys have no ability to affect the output of the NULL algorithms it is irrelevant that the network and the UE derive different keys. Furthermore, section 7.2.4a describes how the algorithm selection is handled for unauthenticated emergency call. This implies that source eNB will forward UE EPS security capability which contains EIA0 and EEA0 only to target eNB. So the target eNB can only select EIA0 for integrity protection and

EEA0 for confidential protection. If the UE does not receive any selection of new AS security algorithms during a intraeNB handover, the UE continues to use the same algorithms as before the handover (see TS 36.331 [21]).

NOTE: If the target eNB is a Rel-8 eNB, it can"t support EIA0 and EEA0. The handover will be rejected because of the failure of algorithm negotiation.

Annex A (normative): Key derivation functions

A.1 KDF interface and input parameter construction

A.1.1 General

All key derivations (including input parameter encoding) for EPS shall be performed using the key derivation function (KDF) specified in TS 33.220 [8]. This clause specifies how to construct the input string, S, to the KDF (which is input together with the relevant key). For each of the distinct usages of the KDF, the input parameters S are specified below.

A.1.2 FC value allocations

The FC number space used is controlled by TS 33.220 [8], FC values allocated for this specification are in range of 0x10 - 0x1F.

A.2 K_{ASME} derivation function

When deriving a K_{ASME} from CK, IK and SN id when producing authentication vectors, and when the UE computes K_{ASME} during AKA, the following parameters shall be used to form the input S to the KDF.

- FC = 0x10,
- P0 = SN id,
- L0 = length of SN id (i.e. 0x00 0x03),
- $P1 = SQN \oplus AK$
- $L1 = \text{length of } SQN \oplus AK \text{ (i.e. } 0x00 \text{ } 0x06)$

The exclusive or of the Sequence Number (SQN) and the Anonymity Key (AK) is sent to the UE as a part of the Authentication Token (AUTN), see TS 33.102. If AK is not used, AK shall be treated in accordance with TS 33.102, i.e. as 000...0.

The SN id consists of MCC and MNC, and shall be encoded as an octet string according to Figure A.2-1.

8	7	6	5	4	3	2	1	
MCC digit 2				MCC digit 1				octet 1
	MNC digit 3				MCC digit 3			
MNC digit 2				MNC digit 1				octet 3

Figure A.2-1 Encoding of SN id as an octet string

The coding of the digits of MCC and MNC shall be done according to TS 24.301 [9].

The input key Key shall be equal to the concatenation $CK \parallel IK$ of CK and IK.

71

A.3 K_{eNB} derivation function

When deriving a K_{eNB} from K_{ASME} and the uplink NAS COUNT in the UE and the MME the following parameters shall be used to form the input S to the KDF.

- FC = 0x11,
- P0 = Uplink NAS COUNT,
- L0 = length of uplink NAS COUNT (i.e. 0x00 0x04)

The input key shall be the 256-bit K_{ASME} .

This function is applied when cryptographically protected E-UTRAN radio bearers are established and when a key change on-the-fly is performed.

A.4 NH derivation function

When deriving a NH from K_{ASME} the following parameters shall be used to form the input S to the KDF.

- FC = 0x12
- P0 = SYNC-input
- L0 = length of SYNC-input (i.e. 0x00 0x20)

The SYNC-input parameter shall be the newly derived K_{eNB} for the initial NH derivation, and the previous NH for all subsequent derivations. This results in a NH chain, where the next NH is always fresh and derived from the previous NH.

The input key shall be the 256-bit K_{ASME} .

A.5 K_{eNB}* derivation function

When deriving a K_{eNB}^* from current K_{eNB} or from fresh NH and the target physical cell ID in the UE and eNB as specified in clause 7.2.8 for handover purposes the following parameters shall be used to form the input S to the KDF.

- FC = 0x13
- P0 = PCI (target physical cell id)
- L0 = length of PCI (i.e. $0x00 \ 0x02$)
- P1 = EARFCN-DL (target physical cell downlink frequency)
- L1 length of EARFCN-DL (i.e. L1 = 0x00 0x02 if EARFCN-DL is between 0 and 65535, and L1 = 0x00 0x03 if EARFCN-DL is between 65536 and 262143)
- NOTE: The length of EARFCN-DL cannot be generally set to 3 bytes for backward compatibility reasons: A Rel-8 entity (UE or eNB) would always assume an input parameter length of 2 bytes for the EARFCN-DL. This would lead to different derived keys if another entity assumed an input parameter length of 3 bytes for the EARFCN-DL.

The input key shall be the 256-bit NH when the index in the handover increases, otherwise the current 256-bit KeNB.

A.6 Void

A.7 Algorithm key derivation functions

When deriving keys for NAS integrity and NAS encryption algorithms from K_{ASME} and algorithm types and algorithm IDs, and keys for RRC integrity and RRC/UP encryption algorithms from K_{eNB} , in the UE, MME and eNB the following parameters shall be used to form the string S.

- FC = 0x15
- P0 = algorithm type distinguisher
- L0 = length of algorithm type distinguisher (i.e. 0x00 0x01)
- P1 = algorithm identity
- L1 = length of algorithm identity (i.e. 0x00 0x01)

The algorithm type distinguisher shall be NAS-enc-alg for NAS encryption algorithms and NAS-int-alg for NAS integrity protection algorithms. The algorithm type distinguisher shall be RRC-enc-alg for RRC encryption algorithms, RRC-int-alg for RRC integrity protection algorithms and UP-enc-alg for UP encryption algorithms (see table A.6-1). The values 0x06 to 0xf0 are reserved for future use, and the values 0xf1 to 0xff are reserved for private use.

Algorithm distinguisher	Value
NAS-enc-alg	0x01
NAS-int-alg	0x02
RRC-enc-alg	0x03
RRC-int-alg	0x04
UP-enc-alg	0x05

Table A.7-1: Algorithm type distinguishers

The algorithm identity (as specified in clause 5) shall be put in the four least significant bits of the octet. The two least significant bits of the four most significant bits are reserved for future use, and the two most significant bits of the most significant bits are reserved for private use. The entire four most significant bits shall be set to all zeros.

For NAS algorithm key derivations, the input key shall be the 256-bit K_{ASME} , and for UP and RRC algorithm key derivations, the input key shall be the 256-bit K_{eNB} .

For an algorithm key of length n bits, where n is less or equal to 256, the n least significant bits of the 256 bits of the KDF output shall be used as the algorithm key.

A.8 K_{ASME} to CK', IK' derivation at handover

This input string is used when there is a need to derive CK' \parallel IK' from K_{ASME} during mapping of security contexts from E-UTRAN to GERAN/UTRAN at handover. K_{ASME} is a 256-bit entity, and so is the concatenation of CK and IK (which are 128 bits each). The following input parameters shall be used.

- FC = 0x16
- P0 = NAS downlink COUNT value
- L0 = length of NAS downlink COUNT value (i.e. 0x00 0x04)

The input key shall be K_{ASME}.

A.9 NAS token derivation for inter-RAT mobility

The NAS-token used to ensure that a RAU is originating from the correct UE during IDLE mode mobility from E-UTRAN to UTRAN and GERAN, shall use the following input parameters.

- FC = 0x17
- P0 = Uplink NAS COUNT
- L0 = length of uplink NAS COUNT (i.e. 0x00 0x04)

The input key shall be the 256-bit K_{ASME} .

A.10 K"_{ASME} from CK, IK derivation during handover

This input string is used when there is a need to derive a K'_{ASME} from concatenation of CK and IK and a NONCE_{MME} during mapping of security contexts between GERAN/UTRAN and E-UTRAN during handover to E-UTRAN.

K'_{ASME} is a 256-bit value. The NONCE_{MME} is a 32-bit value. The following input parameters shall be used.

- FC = 0x18
- $P0 = NONCE_{MME}$
- $L0 = \text{length of NONCE}_{\text{MME}}$ (i.e. $0x00 \ 0x04$)

The input key shall be the concatenation of $CK \parallel IK$.

The generation of $NONCE_{MME}$ shall be sufficiently random such that both the probability of the MME generating equal values of $NONCE_{MME}$ and the probability of an attacker being able to predict future values of $NONCE_{MME}$ over the duration of practical eavesdropping attacks on a particular user are extremely low.

NOTE: A well-seeded strong PRNG would meet this requirement. A true RNG is not required.

A.11 K"_{ASME} from CK, IK derivation during idle mode mobility

This input string is used when there is a need to derive a K''_{ASME} from $CK \parallel IK$, $NONCE_{UE}$, and $NONCE_{MME}$ during mapping of security contexts from GERAN/UTRAN to E-UTRAN. K''_{ASME} is a 256-bit entity, and so is the concatenation of CK and IK (which are 128 bits each). The following input parameters shall be used, where NONCEs are 32 bits long.

- FC = 0x19,
- $P0 = NONCE_{UE}$
- $L0 = \text{length of the NONCE}_{UE}$ (i.e. $0x00 \ 0x04$)
- $P1 = NONCE_{MME}$
- $L1 = \text{length of the NONCE}_{\text{MME}}$ (i.e. 0x00 0x04)

The input key shall be the concatenation of $CK \parallel IK$.

The generation of NONCE_{UE} shall be sufficiently random such that both the probability of the UE generating equal values of NONCE_{UE} and the probability of an attacker being able to predict future values of NONCE_{UE} over the duration of practical eavesdropping attacks on a particular user are extremely low.

NOTE: A well-seeded strong PRNG would meet this requirement. A true RNG is not required.

The generation of $NONCE_{MME}$ shall be as defined in clause A.10.

A.12 K_{ASME} to CK_{SRVCC}, IK_{SRVCC} derivation

This input string is used when there is a need to derive CK_{SRVCC} || IK_{SRVCC} used in CS domain from K_{ASME} during mapping of security contexts between E-UTRAN and GERAN/UTRAN. K_{ASME} is a 256-bit element, and so is the concatenation of CK_{SRVCC} and IK_{SRVCC} (which are 128 bits each).

- FC = 0x1A
- P0 = NAS downlink COUNT value
- L0 = length of NAS downlink COUNT value (i.e. 0x00 0x04)

The input key shall be K_{ASME}.

A.13 K_{ASME} to CK', IK' derivation at idle mobility

This input string is used when there is a need to derive CK' \parallel IK' from K_{ASME} during mapping of security contexts from E-UTRAN to GERAN/UTRAN at idle mobility. K_{ASME} is a 256-bit entity, and so is the concatenation of CK and IK (which are 128 bits each). The following input parameters shall be used.

- FC = 0x1B
- P0 = NAS uplink COUNT value
- L0 = length of NAS uplink COUNT value (i.e. 0x00 0x04)

The input key shall be K_{ASME} .

Annex B (normative): Algorithms for ciphering and integrity protection

B.0 Null ciphering and integrity protection algorithms

The EEA0 algorithm shall be implemented such that it has the same effect as if it generates a KEYSTREAM of all zeroes (see subclause B.1.1). The length of the KEYSTREAM generated shall be equal to the LENGTH input parameter. The generated KEYSTREAM requires no other input parameters but the LENGTH. Apart from this, all processing performed in association with ciphering shall be exactly the same as with any of the ciphering algorithms specified in this Annex.

The EIA0 algorithm shall be implemented in such way that it shall generate a 32 bit MAC-I/NAS-MAC and XMAC-I/XNAS-MAC of all zeroes (see subclause B.2.1). Replay protection shall not be activated when EIA0 is activated. All processing performed in association with integrity (except for replay protection) shall be exactly the same as with any of the integrity algorithms specified in this annex except that the receiver does not check the received MAC.

NOTE 1: The reason for mentioning the replay protection here is that replay protection is associated with integrity.

EIA0 shall be used only for emergency calling for unauthenticated UEs in LSM.

NOTE 2: a UE with a 2G SIM is considered to be in LSM in E-UTRAN.

NOTE 3: EEA0 and EIA0 provide no security.

B.1 128-bit ciphering algorithm

B.1.1 Inputs and outputs

The input parameters to the ciphering algorithm are a 128-bit cipher key named KEY, a 32-bit COUNT, a 5-bit bearer identity BEARER, the 1-bit direction of the transmission i.e. DIRECTION, and the length of the keystream required i.e. LENGTH. The DIRECTION bit shall be 0 for uplink and 1 for downlink.

Figure B.1-1 illustrates the use of the ciphering algorithm EEA to encrypt plaintext by applying a keystream using a bit per bit binary addition of the plaintext and the keystream. The plaintext may be recovered by generating the same keystream using the same input parameters and applying a bit per bit binary addition with the ciphertext.

Figure B.1-1: Ciphering of data

Based on the input parameters the algorithm generates the output keystream block KEYSTREAM which is used to encrypt the input plaintext block PLAINTEXT to produce the output ciphertext block CIPHERTEXT.

The input parameter LENGTH shall affect only the length of the KEYSTREAM BLOCK, not the actual bits in it.

B.1.2 128-EEA1

128-EEA1 is based on SNOW 3G and is identical to UEA2 as specified in [14]. The used IV is constructed the same way as in subclause 3.4 of that TS.

B.1.3 128-EEA2

128-EEA2 is based on 128-bit AES [15] in CTR mode [16]

The sequence of 128-bit counter blocks needed for CTR mode T₁, T₂, ..., T_i, ... shall be constructed as follows:

The most significant 64 bits of T_1 consist of COUNT[0] .. COUNT[31] | BEARER[0] .. BEARER[4] | DIRECTION | 0^{26} (i.e. 26 zero bits). These are written from most significant on the left to least significant on the right, so for example COUNT[0] is the most significant bit of T_1 .

The least significant 64 bits of T_1 are all 0.

Subsequent counter blocks are then obtained by applying the standard integer incrementing function (according to Appendix B1 in [16]) mod 2^{64} to the least significant 64 bits of the previous counter block.

B.2 128-Bit integrity algorithm

B.2.1 Inputs and outputs

The input parameters to the integrity algorithm are a 128-bit integrity key named KEY, a 32-bit COUNT, a 5-bit bearer identity called BEARER, the 1-bit direction of the transmission i.e. DIRECTION, and the message itself i.e MESSAGE. The DIRECTION bit shall be 0 for uplink and 1 for downlink. The bit length of the MESSAGE is LENGTH.

Figure B.2-1 illustrates the use of the integrity algorithm EIA to authenticate the integrity of messages.

Figure B.2-1: Derivation of MAC-I/NAS-MAC (or XMAC-I/XNAS-MAC)

Based on these input parameters the sender computes a 32-bit message authentication code (MAC-I/NAS-MAC) using the integrity algorithm EIA. The message authentication code is then appended to the message when sent. For integrity protection algorithms other than EIA0 the receiver computes the expected message authentication code (XMAC-I/XNAS-MAC) on the message received in the same way as the sender computed its message authentication code on the message sent and verifies the data integrity of the message by comparing it to the received message authentication code, i.e. MAC-I/NAS-MAC.

B.2.2 128-EIA1

128-EIA1 is based on SNOW 3G and is implemented in the same way as UIA2 as specified in [14]. The used IV is constructed the same way as in subclause 4.4 of that TS, with the only difference being that FRESH [0], ... FRESH [31] shall be replaced by BEARER[0] ... BEARER[4] $| 0^{27}$ (i.e. 27 zero bits)

B.2.3 128-EIA2

128-EIA2 is based on 128-bit AES [15] in CMAC mode [17].

The bit length of MESSAGE is BLENGTH.

The input to CMAC mode is a bit string M of length Mlen (see [18, section 5.5]). M is constructed as follows:

 $M_0 ... M_{31} = COUNT[0] ... COUNT[31]$

 M_{32} ... $M_{36} = BEARER[0]$... BEARER[4]

 $M_{37} = DIRECTION$

 M_{38} .. $M_{63} = 0^{26}$ (i.e. 26 zero bits)

 $M_{64} ... M_{BLENGTH+63} = MESSAGE[0] ... MESSAGE[BLENGTH-1]$

and so Mlen = BLENGTH + 64.

AES in CMAC mode is used with these inputs to produce a Message Authentication Code T (MACT) of length Tlen = 32. T is used directly as the 128-EIA2 output MACT[0] \dots MACT[31], with MACT[0] being the most significant bit of T.

Annex C (informative): Algorithm test data

C.1 128-EEA2

This section includes six test data sets; all are presented in hex, while the first is also presented in binary. Some intermediate computational values are included to assist implementers in tracing bugs. Some notation is taken from the specification of CTR mode [16].

Bit ordering should be largely self explanatory, but in particular:

- The 5-bit BEARER is written in hex in a 'right aligned' form, i.e. as a two-hex-digit value in the range 00 to 1F inclusive, with BEARER [0] as the msb of the first digit.
- Similarly the single DIRECTION bit is written in hex in 'right aligned' form, i.e. the DIRECTION bit is the lsb of the hex digit.
- Where the length of plaintext and ciphertext is not a multiple of 32 bits, they are written in hex in a 'left aligned' form, i.e. the least significant few bits of the last word will be zero.

C.2 128-EIA2

This section includes eight test data sets; all are presented in hex, while the first is also presented in binary. Many intermediate computational values are included to assist implementers in tracing bugs. Some notation is taken from the specification of CMAC mode [17].

Bit ordering should be largely self explanatory, but in particular:

- The 5-bit BEARER is written in hex in a 'right aligned' form, i.e. as a two-hex-digit value in the range 00 to 1F inclusive, with BEARER [0] as the msb of the first digit.
- Similarly the single DIRECTION bit is written in hex in 'right aligned' form, i.e. the DIRECTION bit is the lsb of the hex digit.
- Where the length of the message, or of a message sub-block, is not a multiple of 32 bits, it is written in hex in a 'left aligned' form, i.e. the least significant few bits of the last word will be zero.
- NOTE: This section provides both byte aligned and non byte aligned test data sets. For EPS implementation verification, byte alignment test data sets (2, 5 and 8) can be used, as EPS RRC and EPS NAS messages are byte aligned. The non byte aligned test data sets may be used to verify implementations that support non byte aligned messages.
