Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (http://www.etsi.org/ipr).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This European Standard (Telecommunications series) has been produced by ETSI Technical Committee Telecommunications Management Network (TMN), and is now submitted for the Voting phase of the ETSI standards Two-step Approval Procedure.

The present document is part 1 of a multi-part deliverable covering the management information model for the X-type interface between Operations Systems (OSs) of a Virtual Path (VP)/Virtual Channel (VC) cross connected network, as identified below:

Part 1: "Configuration management";

Part 2: "Alarm management";

Part 3: "VP Performance management".

(VC Performance Management aspects are for further study).

Proposed national transposition dates	
Date of latest announcement of this EN (doa):	3 months after ETSI publication
Date of latest publication of new National Standard or endorsement of this EN (dop/e):	6 months after doa
Date of withdrawal of any conflicting National Standard (dow):	6 months after doa

1 Scope

The present document addresses the requirements of network and service providers of Asynchronous Transfer Mode (ATM) cross connected networks for establishing, maintaining and releasing Virtual Path (VP) and / or Virtual Channel (VC) connections (generally denoted as 'VP/VC connections' in the present document), which span several administrative ATM domains. These requirements are satisfied by the use of a standardized interface (the "X-interface") between Operation Systems belonging to different network operators.

Readers of the present document should be made aware that the abbreviation 'PNO' is taken to mean Providing Network Operator. In the previous version of the present document (and related documents), PNO was defined as Public Network Operator. The change in definition has been provided to reflect the change in market conditions for provision of interconnected telecommunications services. However, it is considered necessary to retain the abbreviation 'PNO' because it is found in many of the managed object definitions used to specify the X-interface. It would be disadvantageous to introduce major changes in these managed object definitions, which serve purely technical purposes for management of interconnections only.

The present document contains a general overview describing the different management areas that will be covered in the different X-interface ENs - configuration, alarm and performance - as well as the relationships between them.

The present document describes the configuration management area covering the following aspects:

- a management architecture that shows how the X-interface is to be used between service or network providers;
- the management services and functions needed to manage ATM connections, which span several administrative domains. These management services and functions cover the requirements for the X- interface;
- the management information crossing the X-interface. This management information specification uses the Guidelines for the Definition of Managed Objects GDMO formalism, described in ITU-T Recommendation X.722 [4].

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies.
- A non-specific reference to an ETS shall also be taken to refer to later versions published as an EN with the same number.

3 Definitions and abbreviations

3.1 Definitions

(Some definitions depend on the future acceptance of the "cascaded/mixed mode" as described in annex D. This dependence is already taken into account in these definitions).

For the purposes of the present document, the following terms and definitions apply:

A PNO: PNO where the Initiator starts reserving the end-to-end VP or VC connection

NOTE 1: If the termination point of the connection is at a User access point, this is considered to be the **A User** Access point. The A PNO can be the Initiating PNO, but this is not always the case. It is the Consumer of other PNO's parts of the VP/VC connection.

ATM Accesspoint: means by which a subnetwork offers external interfaces to other subnetworks

NOTE 2: It is associated with an end point of an IPPL.

ATM Interconnection Gateway: ATM access point in one subnetwork, which is associated with an ATM access point in another subnetwork for the purpose of topological interconnection

connection: "transport entity" which is capable of transferring information transparently between "connection points (CP)"

NOTE 3: A "connection" defines the association between the "connection points" and the "connection points" delimit the "connection".

consumer and provider roles of a PNO: with respect to a particular End-to-end connection, a Consumer PNO is a PNO that has delegated the management of a subnetwork connection plus the outgoing link connection to another PNO (being a Provider PNO)

NOTE 4: If, in future, the "cascaded/mixed" mode should be accepted (annex D) a PNO can have both roles at the same time, if it is providing part of the End-to-end connection (being a Provider), and at the same time asks another PNO to provide a part of the End-to-end connection (being a Consumer).

end: point where a connection terminates and which is associated with an address

NOTE 5: The address should be specified in accordance with ITU-T Recommendation M.1400 [2].

end-to-end Connection: overall Connection which can be one of the following types: User-to-user VPC / VCC, Network-to-user VPC, User-to-network VPC or Network-to-network VPC)

NOTE 6: These types are defined in the remainder of this subclause.

NOTE 7: For a given end-to-end connection, any PNO may act in any of the I, A, T or Z PNO roles according to the interconnection requirements to provide the service.

EXAMPLE 1: Figures 2 and 3 provide some examples of end-to-end connections.

Inter PNO Physical Link (IPPL): represents a physical link that offers bidirectional transmission capabilities and connects two subnetworks. Each InterPNOPhysicalLink is terminated by two ATM Access Points which are in charge of emitting failures related to the link or to the access point itself. An IPPL can be realized by any transmission capability (SDH, PDH etc.)

I PNO: initiating PNO. It is the PNO requesting for a particular ATM end-to-end connection. It starts requesting in the subnetwork of the A PNO and ends in the subnetwork of the Z PNO. It controls the end-to-end connection

link: "topological component" which describes the fixed relationship between a "sub-network" and another "sub-network" or "access group". It is defined by an access point on one sub-network, which is associated with an access point on another subnetwork

link connection: link connection is supported by a trail in the server layer network. It is capable of transferring information transparently across a link between two connection points or between a termination connection point and a connection point in the case of a link connection at the boundary of a layer network

NOTE 8: Figures 2 and 3 show how a link connection is a part of an end-to-end connection.

network-to-network VPC: VP "transport entity" formed by the series of "connections" between "termination CPs", starting at an ATM Interconnection Gateway and ending at an ATM Interconnection Gateway. This involves the ATM resources of more than one PNO. The Network-to-network connections that are relevant to the X Interface are of the VP type

(Figure 2 shows how a Network-to-network connection is build up by a series of other connections)

network-to-user VPC: VP "transport entity" formed by the series of "connections" between "termination CPs", starting at an ATM Interconnection Gateway and ending at the Z User Accesspoint in the network of the Z PNO. This involves the ATM resources of more than one PNO. The Network-to-user connections that are relevant to the X Interface are of the VP type

PNO: providing Network Operator. An operator able to provide network resources to customers

pnoVcSubnetwork: topological component used to effect routing and management of ATM cells. It describes the potential for setting up "ATM-VC connections" across the subnetwork. The pnoVcSubnetworks are delineated by ATM AccessPoints and interconnected by "inter-PNO Physical links"

NOTE 9: A pnoVcSubnetwork can be partitioned into interconnected "sub-networks" and "links", but this partitioning is not shown over X Interface. In the context of the present document, one pnoVcSubnetwork represents an ATM network belonging to one PNO.

pnoVpSubnetwork: topological component used to effect routing and management of ATM cells. It describes the potential for setting up "ATM-VP connections" across the subnetwork. The pnoVpSubnetworks are delineated by ATM AccessPoints and interconnected by "inter-PNO Physical links"

NOTE 10: A pnoVpSubnetwork can be partitioned into interconnected "sub-networks" and "links", but this partitioning is not shown over Xinterface. In the context of the present document, one pnoVpSubnetwork represents an ATM network belonging to one PNO.

sub-network: "topological component" used to effect routing and management. It describes the potential for "sub-network connections" across the "sub-network". It can be partitioned into interconnected "sub-networks" and "links". Each "sub-network" in turn can be partitioned into smaller "sub-networks" and "links" and so on. A "sub-network" may be contained within one physical node. In the present document this partition is not used

sub-network connection: subnetwork connection is capable of transferring information transparently across a subnetwork. It is delimited by connection termination points at the boundary of the subnetwork and represents the association between these connection points. It can be a VP or a VC connection

subnetwork view: subtree of the X-interface tree. A subnetwork view belongs to a particular PNO: The PNO at the root of the subtree.

T PNO: transit PNO. This is a PNO using its own subnetwork to perform its required transit part of VP connection. It has a provider role and corresponds to a leaf in the X-interface tree, not being the **Z** side. In the "cascaded/mixed approach" case it can be both a Provider (where it acts as a Transit operator) and a Consumer (where it virtually acts as an Initiating operator)

trail: defined in ES 200 653 [9]

user: consumer of the ATM interconnection, provided by the end-to-end connection

user-to-network VPC: "transport entity" formed by the series of "connections" between "termination CPs", starting at the A User Accesspoint in the network of the A PNO and ending at an ATM Interconnection Gateway. This involves the ATM resources of more than one PNO. The User-to-network connections that are relevant to the X Interface are of the VP type

NOTE 11: Figure 2 shows how a User-to-network connection is build up by a series of other connections.

User-to-user VPC / VCC: "transport entity" formed by the series of "connections" between "termination CPs", starting at the A User Accesspoint in the network of the A PNO and ending at the Z User Accesspoint in the network of the Z PNO. This involves the ATM resources of more than one PNO. The User-to-user connections that are relevant to the X Interface can be of the VP type or the VC type

EXAMPLE 2: Figures 2 and 3 show examples of User-to-user connections.

X-interface tree: with respect to a particular VPC, X-interface relations exist between each Provider PNO and their Consumer PNO. Because each Provider has exactly one Consumer, the X-interface relations between all PNOs involved in the management of a particular VPC form a tree, the X-interface relation tree

NOTE 12: For the cascaded/mixed mode there can be several possible X-interface relation trees; the actual tree is formed at VPC setup. The root of the tree is the Initiating PNO; it uses (via X-interface controls) the PNOs (often Transit PNOs), to which it is connected in the tree via its branches. The most right leaf of the tree is the Z PNO. Figure 2 shows an example of an X-interface tree for the star mode with the A PNO being the Initiator.

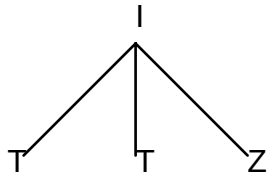

Figure 1: Example of a X-interface tree with the Initiating PNO being the A PNO

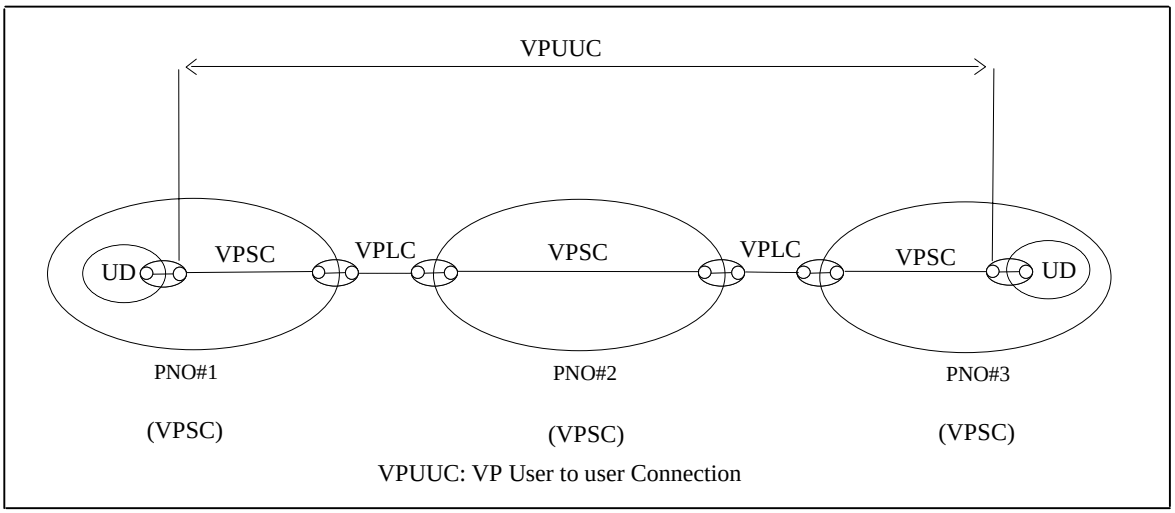
Z PNO: PNO where the Initiator ends reserving the end-to-end connection

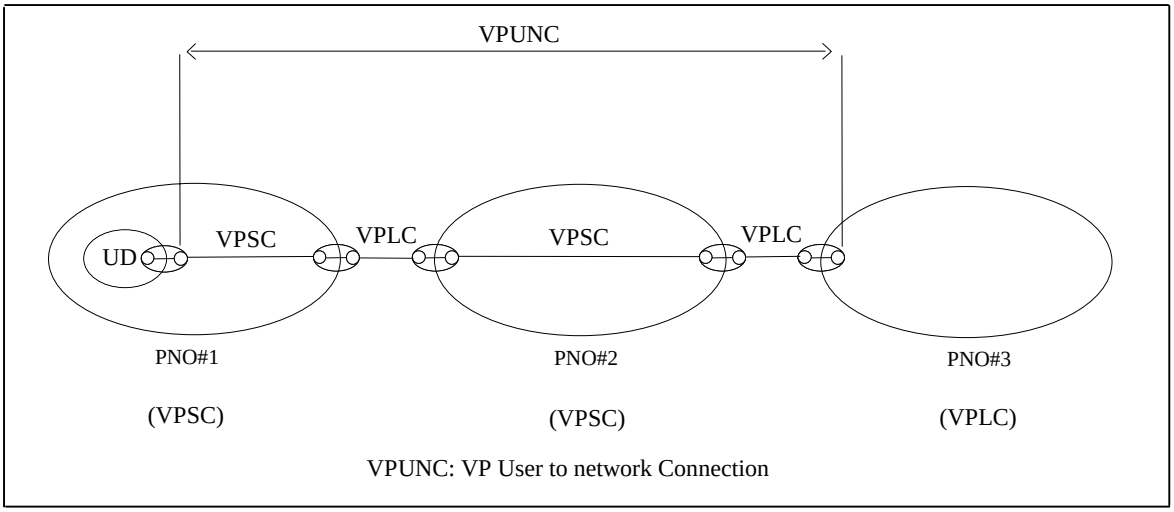
NOTE 13: If the termination point of the connection is at a User accesspoint, this is considered to be the **Z User** Accesspoint. In this case, the I PNO views the Z PNO as a PNO whose subnet is connected to the Z User.

(Note that for User-to-user Connections the VP Link connections that are part of it are not visible across the X-Interface. The Link Connections that terminate the "network side" of an end-to-end Connection are visible over the X-Interface)

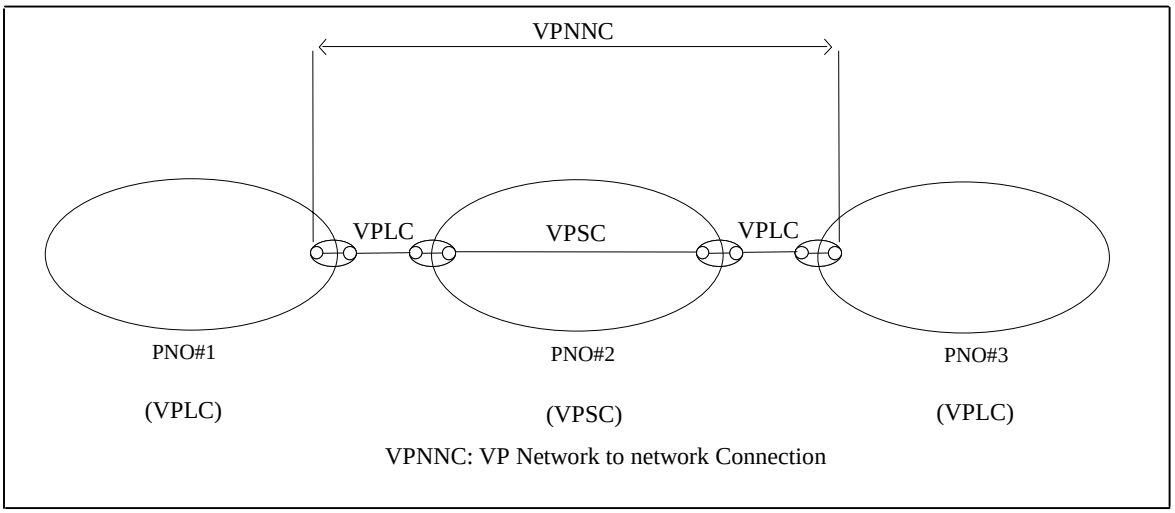
EXAMPLE 3: The following figures 2 and 3 show examples of possible end-to-end connections.



VPUUC: VP User to user Connection



VPUNC: VP User to network Connection



VPNNC: VP Network to network Connection

VPSC: VP Sub Network Connection

VPLC: VP Link Connection

: Not visible across the X-Interface

: Visible across the X-Interface

UD: User Domain
(not visible across the X-Interface)

: Connection points

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

ASN.1	Abstract Syntax Notation One
ATM	Asynchronous Transfer Mode
ATM CP	ATM Connectivity Provider
BM	Business Management
CMIP	Common Management Information Protocol
CMISE	Common Management Information Service Element
CP	Connection Point
CTP	Connection Termination Point
EM	Element Management
GCL	Generic Classes Library
GDMO	Guidelines for the Definition of Managed Objects
IPPL	Inter PNO Physical Link
MF	Management Function
MS	Management Service
MSC	Management Service Component
NE	Network Element
NEF	Network Element Function
NGC	Network Generic Class Library
NM	Network Management
NMC	Network Management Centre
NMS	Network Management System
OS	Operations System
OSF	Operations System Function
OSS	Operations Support System
PNO	Providing Network Operator
QoS	Quality of Service
SM	Service Management
T PNO	Transit PNO
TMN	Telecommunications Management Network

TP	Termination Point
VC	Virtual Channel
VCC	Virtual Channel Connection
VCUUC	Virtual Channel User-to-user Connection
VP	Virtual Path
VPC	Virtual Path Connection
VPLC	Virtual Path Link Connection
VPNC	Virtual Path Network Connection
VPNNC	Virtual Path Network to network Connection
VPNUC	Virtual Path Network to user Connection
VPSC	Virtual Path Subnetwork Connection
VPUNC	Virtual Path User to network Connection
VPUUC	Virtual Path User to user connection

4 Management architecture

This clause describes the functional architecture for the X-interface for ATM cross connected networks. It provides an informative overview of the use of the X-interface and is therefore not normative. (Some definitions partially depend on the future acceptance of the "cascaded/mixed mode" as described in annex D. This dependence is already taken into account.)

Three concepts underpin the functional architecture for the X-interface:

- the X-interface connects two management systems, for the purpose of exchanging service level and/or network level requests with each other;
- consumer/Provider roles (also reflected by Manager / Agent);
- the future use of Star or Cascaded organizational models for communication, or a mixture of both. The choice of the organizational model will be determined by agreements between the PNOs involved in the X-interface.

These concepts are elaborated in the following subclauses.

4.1 X-interface at the Service Management level

In order to clarify the position of the X-interface within the layered management architecture outlined in ITU-T Recommendation M.3010 [7], the following definitions are adopted within the present document:

- the Network Management (NM) level is concerned with connections within the network. This means the control of topological information (subnetworks and the links between subnetworks), and subnetwork connections;
- the Service Management (SM) level is concerned with the overall connection and its associated Quality of Service (QoS).

Since PNOs can request other network operators to deliver a connection with a certain QoS, over the X-interface, without having view of and control over the topology within the individual subnetworks, this interface can be considered at the SM level. However, some functionalities described in the present document are allocated to the NM level, such as the management of topological information of the physical links between the subnetworks.

4.2 Consumer/Provider

The functional architecture for the X-interface for ATM Cross Connected networks is characterized by Consumer/Provider roles: each PNO in a VP Network connection is a Provider of a part of that connection. However, if the "cascaded/mixed mode" will be accepted, some PNOs might also have a Consumer role, since they use parts of other PNO's networks to provide their part of the connection. This is illustrated in figure 4.

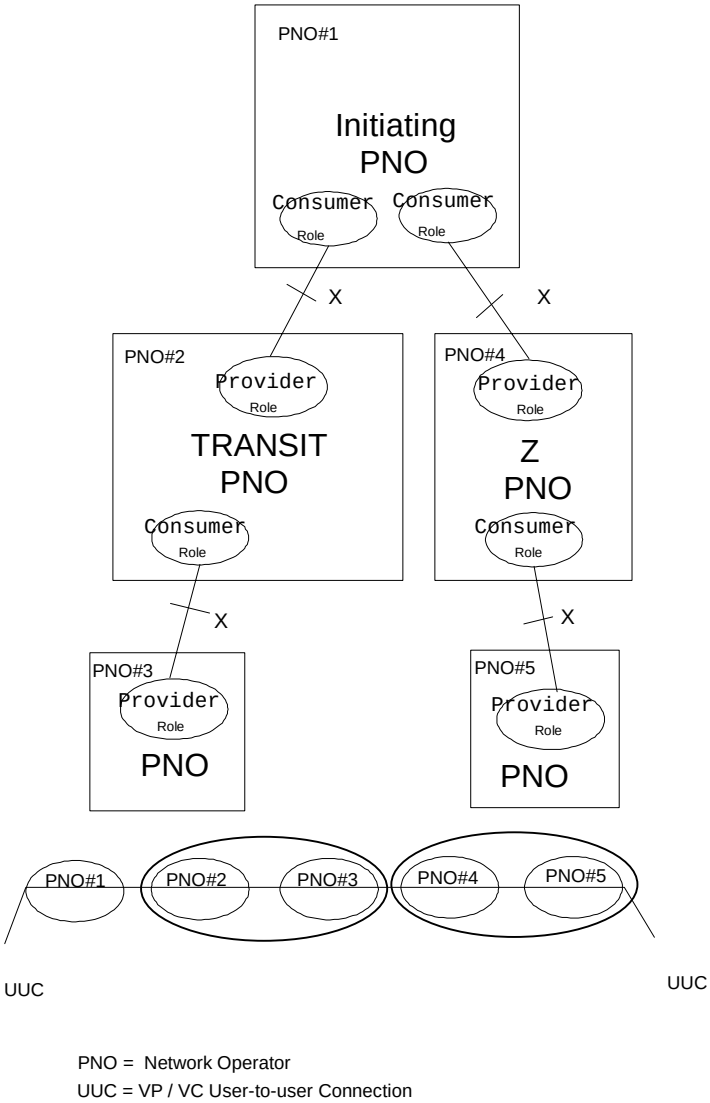

Figure 4: Consumer/provider roles over an X-interface for a specific connection

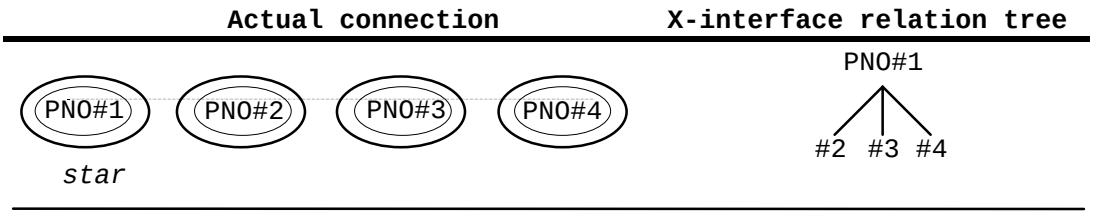
4.3 Organizational model

This subclause describes the organizational model, which will be used in establishing X-interface relationships between PNOs. It is shown in figure 5.



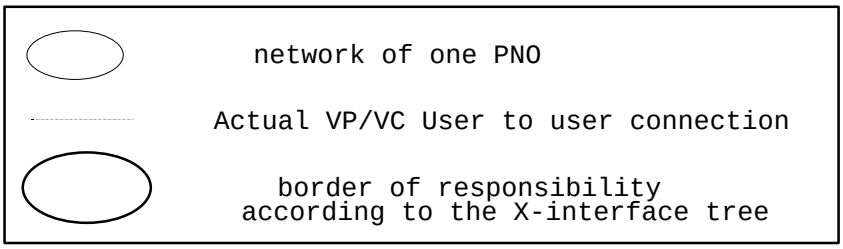


Figure 5: Organizational model

In the *Star* organization as exemplified in the figure above, PNO#1 uses the X-interface relation with all the PNOs involved. This means that PNO#1 has full responsibility for the entire connection and all the other PNOs are only responsible for their own network towards PNO#1.

The Consumer/Provider roles, introduced in subclause 4.2, are reflected by the X-interface tree: in the *Star* example above, PNO#1 has a Consumer role, whereas PNO#2, #3 and #4 have a Provider role.

4.4 Responsibility of PNOs regarding a VP connection

4.4.1 Basic VP connection responsibility rules

This subclause denotes which responsibility is required from each PNO involved in the management of a particular VP/VC connection. The following rules apply:

Rule 1 A PNO is responsible for the management of a particular VPC within its own PNO Subnetwork (if not being the ***Initiating PNO,*** who is responsible towards the connection customer).

Rule 2 Besides the responsibility in rule 1, a PNO is also responsible for the ATM Connection over the physical connection from its PNO Subnetwork to the next PNO Subnetwork on the route of a VPC (seen from the #1 network towards the #2 network).

Subclause 4.4.2 provides examples of the application of the responsibility rules with respect to the management of connection failures

4.4.2 Examples of application of the responsibility rules

The responsibility rules described in subclause 4.4.1 are illustrated by the following scenario description. The scenario starts with the existence of a particular end-to-end VPC between PNOs #1 and #3 via #2 and a particular X-interface relation tree. The scenario describes the occurrence of two cases of failures that need management action; each of them is described as one case of the scenario description. The two cases are an example of part of the life cycle of this particular VPC and take place in sequence. The scenario description is illustrated in figures 6 through 7.

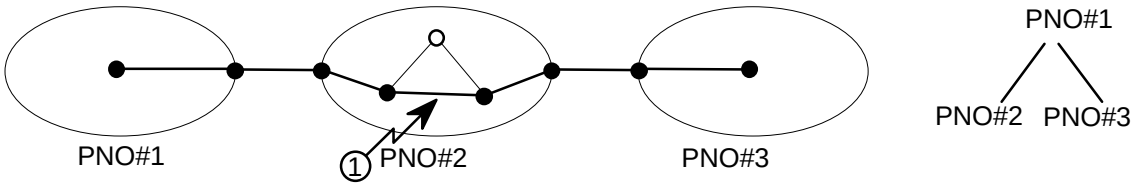

Figure 6: Case 1 of example scenario

Case 1

A fault has occurred in the VPC within the PNO subnetwork of PNO#2. PNO#2 reports to its Consumer PNO (PNO#1) about the failure and indicates that the failure is recoverable. PNO#2 starts its internal reconfiguration process. After reconfiguration has been successfully completed, PNO#2 reports this to its Consumer.

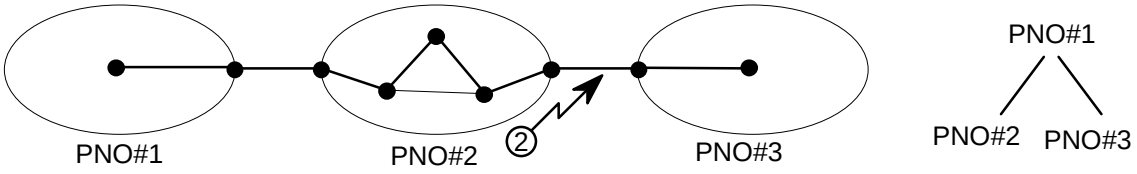

Figure 7: Case 2 of example scenario

Case 2

A fault has occurred in the inter-PNO VP link between PNO#2 and PNO#3. Since this is the outgoing inter-PNO VP link of the PNO subnetwork of PNO#2, PNO#2 is responsible for reporting this failure to its Consumer PNO (PNO#1). PNO#2 reports the failure to PNO#1 and indicates that it can recover the failure. PNO#2 performs recovery actions on the faulty inter-PNO VP link and notifies its Consumer about this and about the Id of the new physical link in the connection.

Detailed use of VP/VC protection for the management of VP/VC failures is provided in annex C.

5 Void

6 Configuration Management and Resilience Requirements

(The term 'VP/VC' is to be read as 'Virtual Path (VP) or Virtual Channel (VC) connection' in the present document).

The following requirements apply for the configuration management functionality and VP/VC resilience in association with use of the X-interface for management of ATM cross-connected networks:

1. It should be possible to set up the following types of Connections:
   - User-to-user VPC and VCC;
   - User-to-network VPC;
   - Network-to-user VPC;
   - Network-to-network VPC.
2. The network side of an end-to-end connection should terminate at an ATM Interconnection Gateway.
3. All transactions should be subject to bi-laterally agreed security processes. A minimum requirement is for 'Access Control', - Refer to annex B for further information.
4. In order to achieve unambiguous identification of entities that are manageable, it is necessary to assign unique names.
5. The X-interface is concerned with the management of the VP and VC Bearer Services.
6. The X-interface for a given PNO may assume either the provider or the consumer role, dependent on the connection.
7. Message transfer should be accomplished in near real time.

   "Real time" is taken to mean "fast enough to be able to control the process". Over the X interface, the delays are often expected to be too large to really be able to control the process. But "Near real time"Seems to be a satisfactory expression if it means "as fast as possible in order to achieve as much process control as possible".
8. Management of X-interface alarms should be undertaken in accordance with the specification defined in [5].
9. Operators are responsible for ensuring that deadlock situations across the X-interface are avoided.
10. The request for a VP/VC Connection which involves a third party PNO that is not providing any of the resources associated with the network connection should be possible. However, a PNO may choose to decline to provide resources for such a connection if no service level agreement has been established between it and the requesting PNO.
11. It should be possible to include in the VP/VC setup requests:
    - Quality of Service;
    - Interconnection Service (A PNO Originating connection, T PNO Transit Connection, Z PNO Terminating Connection);
    - Traffic description;
    - Group Identification (i.e. grouping connections according to initiator-defined criteria);
    - Connection Reference;
    - ATM VPC / VCC resilience type;

- Performance monitoring reporting.

12 It should be possible to set up the end-to-end connection via a preferred route.

13 It should be possible to verify whether the delivered path conforms to the setup request. This also provides tracing of a route of a connection.

14 Data representing the physical and logical resources comprising the subnetwork connection points will need to be maintained. An example of a physical resource is the physical link. Part of the data representing it is the physical link identifier and the allowed bandwidth. An example of a logical resource is a VP and the data representing it is the VPI.

15 Both on-request and scheduled path configuration processes (reservation, cancellation, activation, deactivation) should be supported by the X-interface. Scheduled connection state changes will be required in cases when multiple connections have to be brought into service in a predetermined sequence.

16 Schedule modification (including activation/deactivation schedules) should be supported.

17 Cell rate modification on an active connection should be supported: It should be possible to modify the data rate on an established active connection without the need to deactivate the connection.

18 Grouping of subnetwork connections and link connections in accordance with user defined criteria. end-to-end Connections may need to be grouped according to criteria other than their end points (***A/Z user access points or Interconnection Gateways)***. For example, initiators may want to refer to a mixed group of VP connections as a single unit.

19 It should be possible to set up a new connection that takes the same route as an existing connection group or connection.

20 Cancellation, activation and deactivation operations may be performed on groups of VP or VC connections.

6.1 ATM VP resilience requirements

A PNO playing the Initiator role should be able to choose between 4 different ways of protecting a User to user VP/VC connection, depending on the way the protection is performed. These are:

- Intra-Subnetwork Protection Switching;
- Intra Subnetwork Recovery;
- A-to-Z Fast Re-routing;
- VP Reconfiguration.

It should be possible to apply these four methods of VP/VC protection independently or in combination.

Detailed descriptions of these processes are provided in annex C.

7 Management services

7.1 Management services

For the Configuration Management area, the following Management Service (MS) is identified:

- VP/VC Service Provisioning - Consists of the provisioning of end-to-end VP/VC Connections.

The VP/VC Service Provisioning MS is decomposed into six Management Service Components (MSCs):

- *Establish MSC* - It allows the reservation and activation of a VPC/VCC.
- *Release MSC* - It allows the cancellation of a reservation or the deactivation of a VPC/VCC.
- *Modification MSC* - It allows the modification of the characteristics of a VPC/VCC, during reservation time, e.g. the cell rate.
- *Reconfiguration MSC* - It allows the reconfiguration of the whole or a part of a VPC/VCC, when an unrecoverable failure is detected.
- *Continuity Check MSC* - It allows a Continuity Check over a VPC/VCC.
- *Resilience MSC* - It allows the protection of the User-to-user VP/VC connection, or of a part (VPSC: VP Subnetwork connection, VCSC: VC Subnetwork connection) of it.

7.2 Management Service Components (MSC)

7.2.1 Establish MSC

Summary Description

Establishing a User-to-user VP/VC (VPUUC/VCUUC): PNO, having received a request for a VP/VC Connection, shall perform a check (Destination User Checking-request) with the **Z** PNO to ensure that the **Z** side wishes to accept the requested connection. If the response to this check (Destination User Checking-response) is positive, then another check is made with the **Z** side to see if there is sufficient cell rate available on at least one incoming link to the **Z** PNO (Check Available Cell Rate request). If the response to the check (Check Available Cell Rate -response) is positive, then possible paths will be found between the **A** and **Z** subnetworks, using the topology information. Both of these procedures are optional, in the sense that the Initiating PNO is not obliged to perform them in order to establish a VP Connection.

(A Check Available Cell Rate request may also be made with a transit PNO).

The topology information that describes the inter-PNO links has been made available by the other PNOs, either because they sent it (Topology Info Changes) or because it was read from their MIBs.

Once a path has been selected, each PNO involved in the connection is serially requested to perform a reservation (Reserve VP/VC Subnetwork Connection-request) between a specified input link and a specified adjacent subnetwork. The PNO responds (Reserve VP/VC Subnetwork Connection-response) with the result of this reservation request.

If all PNOs involved in the connection return positive results then the connection can be activated in accordance with the scheduled time specified in the reservation.

If for any reason, a given PNO Subnetwork does not activate the VP/VC Connection in accordance with the schedule, the Initiating PNO shall issue an activation request (Activate VP/VC Subnetwork Connection-request) to this PNO. This one shall then respond (Activate VP/VC Subnetwork Connection-response) with the result of the activation. However, this does not guarantee that the connection is operational.

If a reservation or activation request fails, then each PNO which has already reserved or activated the connection needs to be told to release their resource allocation for this VP/VC Connection (Release VP/VC Subnetwork Connection-request).

As a background task the topology of the network is being tracked, and any changes to either PNO Subnetworks or inter-PNO physical links are sent out to all PNOs (Topology Info Changes).

Performance Monitoring and network-resilience for VPs and VCs can be included as options in the reservation-request. (Reserve Vp Enhanced Subnetwork Connection resp. Reserve Vc Subnetwork Connection). Resilience and performance are described in the Resilience MSC and EN 300 820-3 [8] (Performance Management) respectively. The function Reserve VP Subnetwork Connection is maintained for compatibility purposes.

Establishing a Network-to-user VP (VPNUC): The end-to-end connection setup is simular to the VPUUC setup, apart from the first part of the connection. The "network side" of this end-to-end connection originates at an ATM Interconnection Gateway and is reserved with a link connection (reserve VP Link Connection-request). The responsible PNO responds (Reserve VP Link Connection-response) with the result of this reservation request. It is not possible to include the Performance and Resilience options in the this request. The rest of the end-to-end connection is reserved by using Reserve VP Subnetwork Connection requests.

Establishing a User-to-network VP (VPUNC): The end-to-end connection setup is simular to the VPUUC setup, apart from the last part of the connection. The "network side" of this end-to-end connection terminates at an ATM Interconnection Gateway and is reserved with a link connection (reserve VP Link Connection-request). The responsible PNO responds (Reserve VP Link Connection-response) with the result of this reservation request. It is not possible to include the Performance and Resilience options in the this request. Contrary to the VPUUC-case, a Destination User Checking is not possible.

The other parts of the end-to-end connection are reserved by using Reserve VP Subnetwork Connection requests.

Establishing a Network-to-network VP (VPNNC): The end-to-end connection setup is simular to the VPUUC setup, apart from the first and last part of the connection. They terminate at ATM Interconnection Gateways and are reserved with VP link connections (reserve VP Link Connection-request). The responsible PNO responds (Reserve VP Link Connection-response) with the result of this reservation request. It is not possible to include the Performance and Resilience options in the request. Contrary to the VPUUC-case, a Destination User Checking is not possible.

The remaining parts of this type of end-to-end connection are reserved by using Reserve VP Subnetwork Connection requests.

Simular to the Subnetwork Connection case, a VP Link Connection Reservation can be terminated with a Release VP Link Connection-request. It can be activated with a Activate VP Link Connection-request which has an Activate VP Link Connection-response. However, this does not guarantee that the connection is operational.

List of Functions:

- Destination User Checking *(Optional);*
- Check Available Cell Rate *(Optional);*
- Reserve VC Subnetwork Connection;
- Reserve VP Subnetwork Connection;
- Reserve Enhanced Vp Subnetwork Connection (The VP Subnetwork Connection function with Performance and Resilience options included);
- Reserve VP Link Connection;
- Activate VC Subnetwork Connection;
- Activate VP Subnetwork Connection;
- Activate VP Link Connection;
- Release VC Subnetwork Connection;
- Release VP Subnetwork Connection;
- Release VP Link Connection;
- Topology Info Changes (This is a background function that will provide network topology and status information to be used during the establishment process).

7.2.2 Release MSC

Summary Description

A VP/VC connection can be released for several reasons including expiry of the duration, a service layer request or due to reconfiguration.

There are two parts to the release of a VP/VC connection: deactivation of the VP/VC connection without ending the reservation, e.g. for a scheduled release of a connection (Deactivate VP/VC Subnetwork Connection/Deactivate VP Link Connection), and an unscheduled termination of a reservation with release of the resources (Release VP/VC Subnetwork Connection/ Release VP Link Connection).

Normally, the deactivation is made automatically in accordance with the schedule of the reservation. An explicit deactivation of the VP/VC Connection by the Initiating PNO has to be made in the following circumstances:

- failure of a PNO Subnetwork to deactivate a VP/VC Subnetwork Connection;
- rerouting of a VP/VC end-to-end connection.

The release of the reservation is made by the Initiating PNO by means of issuing a request - *Release VP/VC Subnetwork Connection-request* / *Release VP Link Connection-request* - to the other PNOs involved in the connection to release their portion of the appropriate connection and the PNOs will each respond (*Release VP/VC Subnetwor Connection-response/ Release VP Link Connection-response*) indicating the result of the requested release. This release of the reservation is required if, in setting up a End-to-end connection,a reservation or activation fails at a certain PNO.

A release request can also be received while a connection is active; it should then be released using established and agreed processes.

When a Z PNO has to release a subnetwork connection within its subnetwork the Initiating PNO will be notified (*cancel VP/VC Subnetwork Connection Notification*). The Initiating PNO then can release the connection or reconfigure it.

The same applies to a Link Connection (*cancel VP Link Connection Notification)*

If the initiating PNO does not release the connection the Z PNO can take responsibility for releasing it and send a *delete Notification* to the initiating PNO.

List of Functions:

- Deactivate VC Subnetwork Connection;
- Deactivate VP Subnetwork Connection;
- Deactivate VP Link Connection;
- Cancel VC Subnetwork Connection (Notification);
- Cancel VP Subnetwork Connection (Notification);
- Cancel VP Link Connection (Notification);
- Release VC Subnetwork Connection;
- Release VP Subnetwork Connection;
- Release VP Link Connection.

7.2.3 Modification MSC

Summary Description

Modification is allowed during the reservation time (interval between the VP/VC Connection Reservation creation and deletion) of a VP/VC connection. Changes are possible for the scheduling and for the cell rate of a connection. The path may not be changed while altering the connection.

To perform the Modification of a VPC/VCC, the Initiating PNO requests each PNO involved in providing the End-to-end connection to perform a change reservation (Change Reservation-request), by reserving the new values of the parameters, without cancelling the old ones for its own subnetwork connection. Each PNO responds with the result of this change reservation request (Change Reservation-response). During this time, the reservation is still determined by the old parameter-values.

If any change reservation request fails, then each PNO which has already reserved the changes needs to be told to cancel the altered resource allocation for this VP/VC connection, and to keep the existing one (Cancel Change-request).

If all PNOs involved in the connection return positive results, then the modified connection can be activated by sending an Activate Change-request to each PNO, each of which will then respond with the result of the activation (Activate Change-response).

If any activate change request fails, then the reservation has to be terminated at each involved PNO by the Initiating PNO (Release VP Subnetwork Connection-request for a VpSubnetwork connection, Release VC Subnetwork Connection-request for a VcSubnetwork Connection and Release VP Link Connection-request for a VpLinkConnection).

List of Functions:

- Change Reservation;
- Cancel Change;
- Activate Change;
- Release VC Subnetwork Connection;
- Release VP Subnetwork Connection;
- Release VP Link Connection.

7.2.4 Reconfiguration MSC

Summary Description

Reconfiguration via the X-interface shall be done by the Initiating PNO (I-PNO), after an unrecoverable failure in a VP/VC subnetwork which is supporting part of a VP/VC End-to-end connection.

Reconfiguration in this case means Rerouting, which is the establishment of a replacement connection by the NMS function.

For reconfiguring a VP/VC connection, it will be necessary to find a route around the faulty subnetwork or link supporting the current VP/VC End-to-end connection.

Reconfiguration at the Intiating PNO level consists of Cancelling the Reservation and making a new Establishment using the old parameters. The reconfiguration process can occur at any time.

If the inter_PNO management of the VP/VC connection is organized using the star approach, reconfiguration of a VP/VC connection boils down to deactivating and cancelling the appropriate VP/VC subnetwork connections (Deactivate VP/VC Subnetwork Connection and Release VP/VC Subnetwork Connection) and/or VP Link Connections (Deactivate VP Link Connection and Release VP Link Connection), followed by reserving and activating new ones (Reserve Enhanced VP Subnetwork Connection, Reserve VC Subnetwork Connection and Activate VP/VC Subnetwork Connection) resp. (Reserve VP Link Connection and Activate VP Link Connection). The reconfiguration process is controlled by the I-PNO. Further details can be found in the Establish and Release MSC description.

List of Functions:

- The Establish and Release MSC functions.

7.2.5 Continuity Check MSC

Implementation of theContinuity Check is optional: the initiating PNO can only use the Continuity Check functions with PNOs that are able to support it and allow its usage.

As described in ITU-T Recommendation I.751 [3], the I PNO can delimit part of an End-to-end Connection by applying monitoring objects. Such a delimited part is called segment. A segment is typically in the domain of one PNO; however, it could be extended beyond the control of one PNO by mutual agreement.

NOTE 1: If a PNO does not support Continuity Check functionality, but the PNO's at the extremity of the segment support it, the initiating PNO can use CC functions with the PNO's at the extremity of the segment.

Summary Description

The initiating PNO of a vpConnection (vcConnection) can initiate (and stop) a Continuity Check over a vpConnection (vcConnection) segment.

The Continuity Check may involve one or more PNOs, if all PNOs involved support this by mutual agreement.

The Initiating PNO requests to all the PNOs involved in the vpConnection segment to stop the use of the F4 flow over their managed VP Subnetwork Connection (stopF4Flow-request).

(For a VC Connection, the Initiating PNO requests to all the PNOs involved in the vcConnection segment to stop the use of the F5 flow over their managed VC Subnetwork Connection) (stopF5Flow-request).

Then the Initiating PNO requests the creation of the pnoBidirectionalContinuityMonitor for the Continuity Check to the extremity PNOs of the segment (Create bidirectionalContinuityMonitor for Continuity Check-request). The addressed PNOs respond with positive or negative acknowledgement.

In case of positive response, the Initiating PNO requests the activation of the Source function to the extremity PNOs of the segment (Activate bidirectionalContinuityMonitor Source for Continuity Check-request).

NOTE 2: The Sink function is activated at the bidirectionalContinuityMonitor creation.

When both extremities Sink and Source are activated, the Continuity Check is performed.

When the Continuity Check has to be stopped, the Initiating PNO first asks for the Source deactivation to the extremity PNO of the segment (*Deactivate bidirectionalContinuityMonitor Source for Continuity Check-request*). Then it asks for the bidirectionalContinuityMonitor deletion to the extremity PNOs of the segment (*Delete bidirectionalContinuityMonitor-request*).

At the end of the Continuity Check, the Initiating PNO allows the use of the F4 flow (*allowF4Flow-request*) over their managed VP Subnetwork Connection for all the PNOs involved in the vpConnection segment.

For a vcConnection segment, the Initiating PNO allows the use of the F5 flow (*allowF5Flow-request*) over their managed VC Subnetwork Connection for all the PNOs involved in the vcConnection segment.

During the Continuity Check, if the extremity Sink detects a lossOfContinuity, the concerned PNO sends an indication to the Initiating PNO (*Report of Continuity Check*).

Operational State Changes on Bidirectional Continuity Monitor are notified to the Initiating PNO to inform it that the Continuity Check can't be performed.

List of Functions:

- Create Bidirectional Continuity Monitor for Continuity Check;
- Activate Bidirectional Continuity Monitor Source for Continuity Check;
- Deactivate Bidirectional Continuity Monitor Source for Continuity Check;
- Delete Bidirectional Continuity Monitor;
- Notification of Bidirectional Continuity Monitor Operational State change;
- Stop F4 flow;
- Allow F4 flow;
- Stop F5 flow;
- Allow F5 flow;

- Report of Continuity Check.

7.2.6 Resilience MSC

Summary Description

Implementation of the resilience MSC is optional; it can only be requested by the initiating PNO with PNOs that are able to support it. It is not valid for Vp Link Connections.

To make VP/VC connections (**working** connections) resilient, a PNO playing the initiator role will reserve its connections with a **protection** entity added. On detection of an error on the working connection there will be a change-over to the protection connection. The connection reservation is described in the Establish MSC.

The Initiator can choose among 3 different kinds of resilience mechanisms:

- Intra-Subnetwork Protection Switching;
- Intra Subnetwork Recovery;
- A-to-Z Fast re-routing.

It is possible to combine these three options in any combination.

It is presumed that the Agent will attempt to recover the working VP/VC, whether or not resilience has been requested. This recovering of the working VP or VC is considered to be *Intra Subnetwork Recovery without the use o pre-assigned resources,* and is not considered further here.

Intra-Subnetwork Protection Switching: this is performed within a Subnetwork. The working connection and the protection connection have the same end points, and the detection of an error and the following change-over to the protection traffic occur automatically, without any network-management action. The protection connection uses dedicated and pre-assigned capacity.

The network elements at the endpoints shall be able to switch to the protection connection.

Two types of pre-assignment are known from ITU-T Recommendation I.630 [6]. These are the (1:1) configuration, where the protection connection does not convey working traffic until the working connection experiences errors, and the (1+1) configuration, where the working and protection connection convey the working traffic simultaneously.

The request for this kind of resilience is performed by sending an optional parameter in the reservation request for the working VP *(Reserve Enhanced VP Subnetwork Connection*) or VC (*Reserve VC Subnetwork Connection).*

If this reservation is accepted, the response (*Reserve Enhanced VP Subnetwork Connection-response) / (Reserve VC Subnetwork Connection-response)* will also indicate if the Agent is able to provide protection switching. If it is not provided, the I PNO can decide whether to use the reservation anyway or to end it (See *Establish MSC*).

A change over to protecting traffic is reported to the I PNO. This is described in the VP/VC alarm reporting MS of EN 300 820-2 [5]: Alarm Management.

Intra Subnetwork Recovery: this is performed within a Subnetwork. The working VP/VC Subnetwork connection and the protection connection have their endpoints in common. In response to an error on the working VP Subnetwork connection the PNO with the network-error needs to trigger the recovery mechanism internally.

A recovery action may follow a failed attempt to overcome a fault by protection switching or it could be the only strategy implemented to protect a circuit.

The request for this kind of resilience mechanism is performed by sending an optional parameter in the reservation request for the working VP (*Reserve Enhanced VP Subnetwork Connection*) or VC (*Reserve VC Subnetwork Connection).*

If this reservation is accepted, the response (*Reserve Enhanced VP Subnetwork Connection-response / Reserve VC Subnetwork Connection-response)* will also indicate if the Agent is able to provide the recovery mechanism. If it is not provided, the I PNO can decide whether to use the reservation anyway or to end it. (See *Establish MSC*).

An attempt of the Agent to establish recovery will be reported to the I PNO. The result of this attempt is also reported. (VP alarm reporting MS of EN 300 820-2 [5]).

A-to-Z Fast re-routing: this provides a global (A-User to Z-User) resilience mechanism, that covers both intra-PNO and inter-PNO failures. The VP/VC is duplicated on a completely different route, notably using different inter-PNO links. The working VP/VC connection and the protection VP/VC connection only have the A user accesspoint and the Z user accesspoint in common. In a Transit network, they do not have any accesspoint in common. They convey the same traffic simultaneously. In case of an error the change-over to protecting resources is performed by the A-PNO and the Z-PNO, following a management request of the I PNO. *(Switch To Subnetwork Connection)*

Fast re-routing may follow failed attempts to overcome a fault by protection switching and/or recovery, or it could be the only strategy implemented to protect a circuit.

In general, the protection VP/VC is reserved after the working VP/VC has been reserved, by making a reservation request with two optional parameters indicating the fast-re-routing case and a reference to the working connection respectively (*Reserve Enhanced VP Subnetwork Connection / Reserve VC Subnetwork Connection).* The response (*Reserve Enhanced VP Subnetwork Connection-response / Reserve VC Subnetwork Connection-response)* will indicate if the working connection exists or if the Agent is able to provide fast re-routing. If at least one of these conditions do not apply the working connection can not be protected with Fast re-routing mechanism.

The working VP/VC shall have been reserved before, with an optional parameter in the reservation request requesting that the working VP/VC is to be protected by fast-re-routing.

If the working reservation is accepted, the response (*Reserve Enhanced VP Result-response / Reserve VC Subnetwork Connection-response*) will also indicate if the Agent is able to provide fast re-routing. If it is not provided, the I PNO can decide whether to use the reservation anyway or to end it (See *Establish MSC*).

If protection- and working connections use different T-networks they can be reserved, in those T-networks, without the fast-rerouting option. (*Reserve Enhanced VP Subnetwork Connection / Reserve VC Subnetwork Connection)*.

After having received an X interface alarm message that indicates a fault on the working connection, the I PNO can request the A and the Z PNO to change over, at their User Access Points, to the traffic arriving over the protection circuit. (*Switch To SubnetworkConnection-request*)

The A- and the Z Agents respond with the result of this request. (*Switch To SubnetworkConnection-result)*

If the request is unsuccessful the I PNO can consider reconfiguration of the overall VP/VC connection. (*Reconfiguration MSC*)

Using the function (*Switch To SubnetworkConnection*) it is possible to change back to the original working connection when it has recovered.

Figure 8 and the associated text contain an additional explanation of the processes that are associated with the different kinds of Network Resilience for a T PNO.

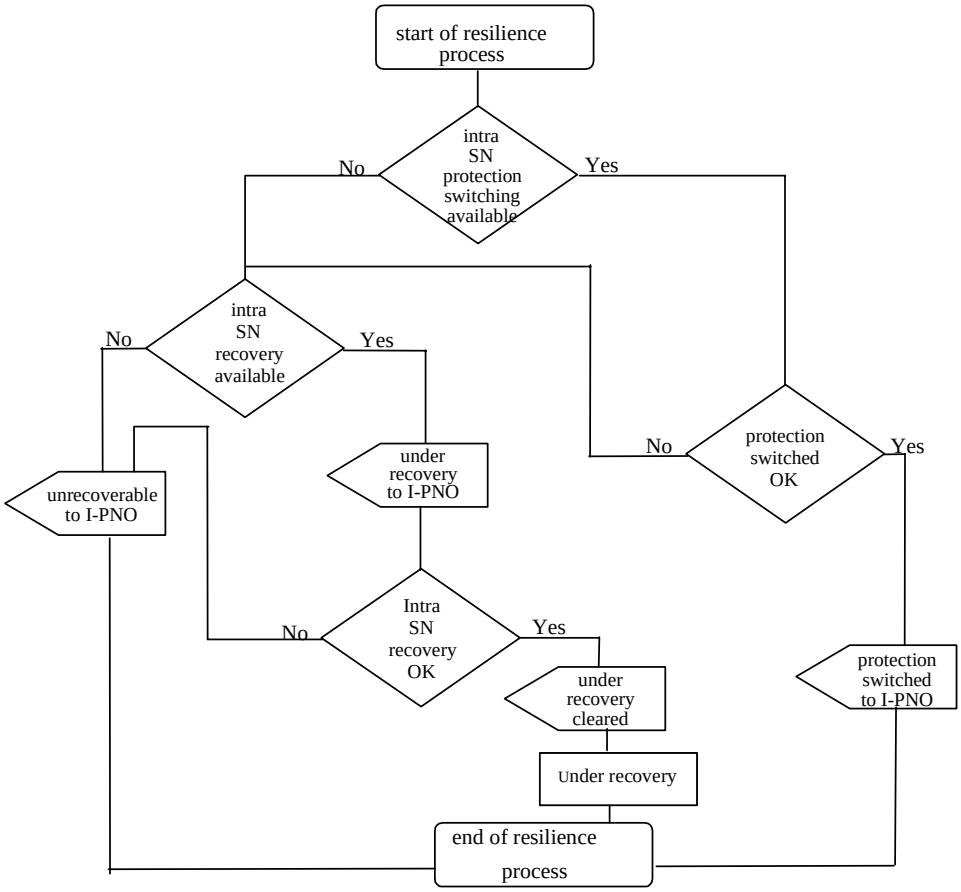

Figure 8: Resilience Process

If a fault occurs on a reserved connection in the PNO domain, different situations can occur, as represented in figure 8. The following text does not cover all possibilities, but can help to understand the diagram itself.

For the role of A/T and Z-PNO

a) The Subnetwork connection was requested with "Intra-Subnetwork Protection Switching". In This case the PNO will restore the Subnetwork connection automatically and will inform the I-PNO with a "Protection Switching Notification".

b) If a) fails and/ or Protection Switching is not requested and/ or Recovery was requested for the Subnetwork connection. In this case the recovery process at the PNO will be started as quickly as possible to restore the failed part of the Subnetwork connection and an "Under Recovery" Notification [5] will be sent to the I-PNO.

c) If b) recovers correctly a "Under Recovery, Cleared" Notification [5] is sent to the I-PNO.
If b) fails to recover, an "Unrecoverable" Notification [5] is sent to the I-PNO.

Only for the role of A and Z-PNO

If the connection has been requested to support Fast Re-routing, the following cases may happen:

a) At any point in time an action can be received from the I-PNO, requesting to switch from the working connection to the protection connection.

b) If d) happens while a recovery process is occurring, this will not be stopped; the recovery process will continue as explained in a) to c).

Only for the role of I-PNO

If, as a consequence of receiving an alarm from the A/Z-PNO, the I-PNO has requested to A- and Z-PNO Fast Re-routing, the following situations may happen (please not that the following are not Normative behaviours, but rather guidelines):

a) Both a- and Z-PNO switch successfully to the protection connection. If the PNO who experienced the fault eventually recovers, the I-PNO can, in future switch again to the original connection, using the same action on A- and Z-PNO.

b) If the A- or Z-PNO can't perform Fast Re-routing; e.g. A-PNO:

- the I-PNO can send a Fast Re-routing action to the successful PNO (switch To Snc) (in this example the Z-PNO), to return to the previous situation;
- the I-PNO can try to re-send the Fast Re-routing request to the unsuccessful PNO (switch To Snc) (in this example the A-PNO) and see if it works.

c) If nothing works and the failure is unrecoverable, the I-PNO may:

- release the whole end-to-end connection;
- use the Reconfiguration process in order to re-create a VP from scratch.

Note that IPPL failures have to be sent to all PNOs.

List of Functions:

Reserve Enhanced VP Subnetwork Connection

Reserve VC Subnetwork Connection

- Switch To Subnetwork Connection

7.3 Management Functions (MF)

For a mapping between the Management Functions and the actual CMISE functions, refer to annex D.

7.3.1 Activate Bidirectional Continuity Monitor Source for Continuity Check

This function requests to the extremity PNOs of the segment involved in a segment Continuity Check to activate the Source mechanism for OAM flow.

NOTE: The Sink mechanism is activated at bidirectionalContinuityMonitor Creation.

The message associated with this function will be sent by the Initiating PNO to the extremity PNOs of the segment. The extremity PNOs of the segment respond with the result of the activation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function.

Request -	Bidirectional continuity monitor Id	Identity of the bidirectional continuity monitor to activate
	ControlContinuity CheckInformation	Activate Source
Response	Activation result	Result of the activation attempt

7.3.2 Activate Change

This function requests a PNO to activate a reserved connection of which the parameters have been modified.

The PNO should respond with the result of the activation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function.

Request-	VP/VC Connection id	Identity assigned to the connection
Response-	Activate Change result	Result of the activate change attempt

7.3.3 Activate VC Subnetwork Connection

This function requests a PNO to activate a reserved VC Subnetwork connection between the specified input and output ports of its subnetwork. (Between the user and the output port for the **A** subnetwork or between the input port and the user for the **Z** subnetwork). The PNO should respond with the result of the activation.

This MF is applied only if if the connection is not activated automatically in accordance with the reserved schedule.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VC Connection id	Identity assigned to the connection
Response-	Activation result	Result of the activation attempt

7.3.4 Activate VP Link Connection

This function requests a PNO to activate a reserved VP Link connection. The PNO should respond with the result of the activation.

This MF is applied only if if the connection is not activated automatically in accordance with the reserved schedule.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection id	Identity assigned to the connection
Response-	Activation result	Result of the activation attempt

7.3.5 Activate VP Subnetwork Connection

This function requests a PNO to activate a reserved VP Subnetwork connection between the specified input and output ports of its subnetwork. (Between the user and the output port for the **A** subnetwork or between the input port and the user for the **Z** subnetwork). The PNO should respond with the result of the activation.

This MF is applied only if if the connection is not activated automatically in accordance with the reserved schedule.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection id	Identity assigned to the connection
Response-	Activation result	Result of the activation attempt

7.3.6 Allow F4 flow

This function allows a PNO to use the F4 flow over a Subnetwork Connection or over an inter-PNO link.

The message associated with this function is sent by the Initiating PNO to all the PNOs involved in a segment Continuity Check when this check is ended.

It is confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request -	PNO VP Subnetwork Connection Id	Identity assigned to the concerned PNO Subnetwork Connection
	Allow test	
Response	Activation result	Result of the activation attempt

7.3.7 Allow F5 flow

This function allows a PNO to use the F5 flow over a Subnetwork Connection or over an inter-PNO link.

The message associated with this function is sent by the Initiating PNO to all the PNOs involved in a segment Continuity Check when this check is ended.

It is confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request -	PNO VC Subnetwork Connection Id	Identity assigned to the concerned PNO Subnetwork Connection
	Allow test	
Response	Activation result	Result of the activation attempt

7.3.8 Cancel Change

This function requests a PNO to cancel the previously requested changes to the parameters of a VP/VC connection.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP/VC Connection Id	Identity assigned to the connection
Response-	Cancel Change Result	Result of the cancel change attempt

7.3.9 Cancel VC Subnetwork Connection

This function allows a Z PNO to notify the initiating PNO that it wants the initiator to release, for a particular reason, a subnetwork connection in the Z PNO's net.

It is a non-confirmed type of operation. The following parameters are associated with the Request and Respons primitives of the function:

Request	VC Connection Id	Identity assigned to the connection
	disconnect Cause	The Z PNO's reason for his request
Response	None	

7.3.10 Cancel VP Link Connection

This function allows a PNO to notify the initiating PNO that it wants the initiator to release, for a particular reason, a Link connection in its domain.

It is a non-confirmed type of operation. The following parameters are associated with the Request and Respons primitives of the function:

Request	VP Connection Id	Identity assigned to the connection
	disconnect Cause	The PNOs' reason for his request
Response	None	

7.3.11 Cancel VP Subnetwork Connection

This function allows a Z PNO to notify the initiating PNO that it wants the initiator to release, for a particular reason, a subnetwork connection in the Z PNO's net.

It is a non-confirmed type of operation. The following parameters are associated with the Request and Respons primitives of the function:

Request	VP Connection Id	Identity assigned to the connection
	disconnect Cause	The Z PNO's reason for his request
Response	None	

7.3.12 Change Reservation

This function requests a PNO to check if it has resources available to support the altered parameters for an existing subnetwork connection which is specified by the connection identifier.

Upon reception of this request a transit PNO should check the availability of the new scheduler between the linked input and output ports of its subnetwork; if it is an A or a Z PNO the check has to be done between the input/output port of the subnetwork and the user.

The PNOs respond with the new scheduling parameters for the already established connection if the check has been successful, or with an error message if the check has shown no possiblity to change the scheduler. The connection reservation will be unchanged for either of the situations.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP/VC Connection Id	Identity assigned to the connection
	Forward traffic descriptor (new)	Altered peak cell rate from **A** to **Z**
	Backward traffic descriptor (new)	Altered peak cell rate from **Z** to **A**
	Schedule (new)	Changed Schedule
Response-	Change reservation result	Result of the change reservation attempt

7.3.13 Check Available Cell Rate

This function checks that the **Z** PNO has a particular cell rate available on at least one of its incoming inter-PNO links. It is only a check that the **Z** PNO has the cell rate available and not for the total amount of available cell rate.

The request can also be sent to a transit PNO. In this case the Agent-PNO will always consider itself as the Z side of the link with regard to the direction of the bandwidth in the request.

The message will include the peak cell rate required in both directions for a planned VP/VC connection. The receiving PNO (**Z** PNO or Transit-PNO in the Initiating PNO's view) will then check on which of its inter-PNO links this cell rate is available and respond to the Initiating PNO with the corresponding list of neighbouring PNOs.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP/VC Connection Id	Identity assigned to the connection
	Forward traffic descriptor	Peak cell rate from **A** to **Z**
	Backward traffic descriptor	Peak cell rate from **Z** to **A**
	PNO Subnetwork Id	Identity of Initiating PNO
	Schedule	List of activation times, dates and durations
Response-	Check Available Cell Rate Response	List of inter-PNO links which can accommodate the requested cell rate

7.3.14 Create Bidirectional Continuity Monitor for Continuity Check

A continuity check OAM flow is used in a vpConnection/vcConnection in order to monitor the continuity of this vpConnection/vcConnection.

The Initiating PNO creates a bidirectionalContinuityMonitor for Continuity Check at the entry edge or exit edge of the extremity PNOs of the segment.

For that creation, the Initiating PNO sends a Create bidirectionalContinuityMonitor message to the extremity PNOs of the segment.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request -	Bidirectional continuity monitor Id	Identity assigned to the created bidirectional continuity monitor
	FlowDirection	Direction in/from which the OAM flow is generated/received
Response	Creation result	Result of the create

The bidirectionalContinuityMonitor Sink mechanism represents the sink of a segment OAM flow. The bidirectionalContinuityMonitor Sink mechanism is activated at object creation.

7.3.15 Deactivate Bidirectional Continuity Monitor Source for Continuity Check

This function requests the extremity PNOs of the segment involved in a segment Continuity Check to deactivate the Source/Sink mechanism for OAM flow.

The function is used first to deactivate the Source mechanism at each extremity. The Sink mechanism will be deleted at object deletion.

The message associated with this function will be sent by the Initiating PNO to the extremity PNOs of the segment. The extremity PNOs of the segment respond with the result of the deactivation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request -	Bidirectional continuity monitor Id	Identity of the bidirectional continuity monitor to deactivate
	ControlContinuity CheckInformation	Deactivate Source
Response	Deactivation result	Result of the deactivation attempt

7.3.16 Deactivate VC Subnetwork Connection

This function requests a PNO to deactivate the Subnetwork connection between the specified input and output ports of its subnetwork. (Between the user and the output port for the ***A*** subnetwork or between the input port and the user for the ***Z*** subnetwork). ThePNO should respond with the result of the deactivation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VC Connection Id	Identity assigned to the connection
Response-	Deactivation Result	Result of the deactivation attempt

7.3.17 Deactivate VP Link Connection

This function requests a PNO to deactivate the specified Link Connection. ThePNO should respond with the result of the deactivation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
Response-	Deactivation Result	Result of the deactivation attempt

7.3.18 Deactivate VP Subnetwork Connection

This function requests a PNO to deactivate the Subnetwork connection between the specified input and output ports of its subnetwork. (Between the user and the output port for the **A** subnetwork or between the input port and the user for the **Z** subnetwork). ThePNO should respond with the result of the deactivation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
Response-	Deactivation Result	Result of the deactivation attempt

7.3.19 Delete Bidirectional Continuity Monitor

The Initiating PNO deletes bidirectionalContinuityMonitor objects created for Continuity Check at the entry edge or exit edge of the extremity PNOs of the segment.

For that deletion, the Initiating PNO sends a Delete bidirectionalContinuityMonitor message to the extremity PNO of the checked segment of the connection after the end of the check.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request -	Bidirectional continuity monitor Id	Identity assigned to the deleted bidirectional continuity monitor
Response	Deletion result	Result of the delete

7.3.20 Destination User Checking

When a new VP/VC connection establish request is received from the Service Layer, it is reasonable to verify that the **Z** user is able or wants to support the requested connection before expending network resources in establishing the connection. From a PNO's point of view only a check that the **Z** PNO can accept the connection is performed.

On receiving a VP/VC connection establish request from the Service Layer, the Initiating PNO will send out a Destination User Checking-request message to the **Z** PNO, and will include the peak cell rate (in both directions), and the **A** and **Z** addresses for the requested VP Connection. The **Z** PNO will then perform the **Z** user checking and respond with the result to the Initiating PNO.

In case the **Z** user is under the **Z** PNO domain (star approach), the **Z** PNO will perform the **Z** user checking and respond with the result to the Initiating PNO.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP/VC Connection Id	Identity assigned to the connection
	A Address	E.164 address of the **A** user
	Z Address	E.164 address of **Z** user
	Forward Traffic Descriptor	Peak cell rate from **A** to **Z**
	Backward Traffic Descriptor	Peak cell rate from **Z** to **A**
	Schedule	List of activation times, dates and durations
	PNO Subnetwork Id	Identity of the Initiating PNO

Response-	Check Response	Result of **Z** user check
	Check Reason	Reason for failure of check
	PNO Subnetwork Id	Identity of the reporting PNO

7.3.21 Notification of Bidirectional Continuity Monitor Operational State Change

When an Operational State change occurs on a pnoBidirectionalContinuityMonitor, the Initiating PNO of the vpConnection (vcConnection) shall be informed that the Continuity Check can't be performed or shall be stopped if it is already started.

This Operational State change will be sent using the normal stateChange Notification.

7.3.22 Release VC Subnetwork Connection

This function requests a PNO to release an already confirmed reservation and to free the resources.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VC Connection Id	Identity assigned to the connection
Response-	Release Result	Result of the cancel reservation attempt

7.3.23 Release VP Link Connection

This function requests a PNO to release an already confirmed reservation and to free the resources.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
Response-	Release Result	Result of the cancel reservation attempt

7.3.24 Release VP Subnetwork Connection

This function requests a PNO to release an already confirmed reservation and to free the resources.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
Response-	Release Result	Result of the cancel reservation attempt

7.3.25 Report of Continuity Check

The bidirectional continuity monitor receives a continuity check OAM flow in a vpConnection (vcConnection).

When the bidirectional continuity monitor Sink part detects a disruption on the received flow, a Report of Continuity Check Notification is sent to the Initiating PNO.

It is a non-confirmed type of operation. The following parameters are associated with the Request primitives of the function:

Request -	Bidirectional continuity monitor Id	Identity assigned to the bidirectional continuity monitor which has detected the connection disruption
	Probable Cause	Set to LOC: loss of continuity (17)

7.3.26 Reserve Enhanced VP Subnetwork Connection

This function requests the involved PNO to reserve a path across its subnetwork: between a specified input point and an adjacent subnetwork if performs the **T** subnetwork role, between the A User and an adjacent subnetwork if it performs **A** subnetwork role or between a specified input port and the Z user, if it performs the Z subnetwork role.The PNO responds with the result of the reservation.

The request for Performance can be included as an option. The response will indicate if the request for performance measurements was successful. Also, the kind of resilience can be requested as an option. In this case the response indicates whether the resilience has been provided in addition to the successful result response.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
	Subnetwork Connection Id (nearend)	Identification of the nearend Subnetwork connection
	AccesPoint Id (nearend)	Identification of the nearend Accesspoint
	VP Id (nearend)	Identification of the nearend VPI
	PNO Subnetwork Id (far-end)	Identification of the adjacent PNO Subnetwork
	A Address	E.164 address of **A** user
	Z Address	E.164 address of **Z** user
	Z VPI (optional)	VPI to be used by the **Z** PNO only to allow user transparency of reconfiguration
	Forward traffic descriptor	Peak cell rate from **A** to **Z**
	Backward traffic descriptor	Peak cell rate from **Z** to **A**
	Forward QoS class	An indication of the class of QoS
	Backward QoS class	An indication of the class of QoS
	Schedule	List of activation times, dates and durations
	Performance Monitoring (optional)	Indication if Performance Monitoring has been requested
	Resilience Kind (optional)	Kind of Network Resilience
	Related Subnetwork Connection (optional)	Pointer at Subnetwork connection that is to be protected by Fast re-routing
Response-	Subnetwork Connection Id (far-end)	Identification of the far-end Subnetwork Connection
	Reservation result	Result of the reservation attempt, including the result of the request performance and for resilience

7.3.27 Reserve VC Subnetwork Connection

This function requests the involved PNO to reserve a path across its subnetwork: between a specified input point and an adjacent subnetwork if performs the **T** subnetwork role, between the A User and an adjacent subnetwork if it performs **A** subnetwork role or between a specified input port and the **Z** user, if it performs the **Z** subnetwork role. The PNO responds with the result of the reservation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VC Connection Id	Identity assigned to the connection
	Subnetwork Connection Id (nearend)	Identification of the nearend Subnetwork connection
	AccesPoint Id (nearend)	Identification of the nearend Accesspoint
	VP Id (nearend)	Identification of the nearend VPI
	VC Id (nearend)	Identification of the nearend VCI
	PNO Subnetwork Id (far-end)	Identification of the adjacent PNO Subnetwork
	A Address	E.164 address of **A** user
	Z Address	E.164 address of **Z** user
	Z VPI (optional)	VPI to be used by the **Z** PNO only to allow user transparency of reconfiguration
	Z VCI (optional)	VCI to be used by the **Z** PNO only to allow user transparency of reconfiguration
	Forward traffic descriptor	Peak cell rate from **A** to **Z**
	Backward traffic descriptor	Peak cell rate from **Z** to **A**
	Forward QoS class	An indication of the class of QoS
	Backward QoS class	An indication of the class of QoS
	Schedule	List of activation times, dates and durations
Response-	Subnetwork Connection Id (far-end)	Identification of the far-end Subnetwork Connection
	Reservation result	Result of the reservation attempt.

7.3.28 Reserve VP Link Connection

This function requests the involved PNO to reserve a Vp connection across an inter-Pno Link with an adjacent subnetwork. The PNO responds with the result of the reservation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
	PNO Subnetwork Id	Identification of the adjacent PNO Subnetwork
	nearEndAccesspointId	Identification of the accesspoint that is to be used for the Link Connection
	VP Id (nearend)	Identification of the VP Id
	Forward traffic descriptor	Peak cell rate from **A** to **Z**
	Backward traffic descriptor	Peak cell rate from **Z** to **A**
	Forward QoS class	An indication of the class of QoS
	Backward QoS class	An indication of the class of QoS
	Schedule	List of activation times, dates and durations
Response-	Reservation result	Result of the reservation attempt.

7.3.29 Reserve VP Subnetwork Connection

This function requests the involved PNO to reserve a path across its subnetwork: between a specified input point and an adjacent subnetwork if performs the ***T*** subnetwork role, between the A User and an adjacent subnetwork if it performs ***A*** subnetwork role or between a specified input port and the **Z** user, if it performs the ***Z*** subnetwork role. The PNO responds with the result of the reservation.

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	VP Connection Id	Identity assigned to the connection
	Subnetwork Connection Id (nearend)	Identification of the nearend Subnetwork connection
	AccesPoint Id (nearend)	Identification of the nearend Accesspoint
	VP Id (nearend)	Identification of the nearend VPI
	PNO Subnetwork Id (far-end)	Identification of the adjacent PNO Subnetwork
	A Address	E.164 address of **A** user
	Z Address	E.164 address of **Z** user
	Z VPI (optional)	VPI to be used by the **Z** PNO only to allow user transparency of reconfiguration
	Forward traffic descriptor	Peak cell rate from **A** to **Z**
	Backward traffic descriptor	Peak cell rate from **Z** to **A**
	Forward QoS class	An indication of the class of QoS
	Backward QoS class	An indication of the class of QoS
	Schedule	List of activation times, dates and durations
Response-	Subnetwork Connection Id (far-end)	Identification of the far-end Subnetwork Connection
	Reservation result	Result of the reservation attempt.

7.3.30 Stop F4 flow

This function inhibits a PNO from using the F4 flow over a Subnetwork Connection or over an inter-PNO link.

The message associated with this function is sent by the Initiating PNO to all the PNOs involved in a segment Continuity Check when before this check is performed.

It is a confirmed type of operation. The following parameters are associated with the Request and response primitives of the function:

Request -	PNO VP Subnetwork Connection Id	Identity assigned to the concerned PNO Subnetwork Connection
	Inhibit test	
Response	Deactivation result	Result of the deactivation attempt

7.3.31 Stop F5 flow

This function inhibits a PNO from using the F5 flow over a Subnetwork Connection or over an inter-PNO link.

The message associated with this function is sent by the Initiating PNO to all the PNOs involved in a segment Continuity Check when before this check is performed.

It is a confirmed type of operation. The following parameters are associated with the Request and response primitives of the function:

Request -	PNO VC Subnetwork Connection Id	Identity assigned to the concerned PNO Subnetwork Connection
	Inhibit test	
Response	Deactivation result	Result of the deactivation attempt

7.3.32 Switch To Subnetwork Connection

This function requests the involved (A and Z) PNO's to change over, at the endpoint that represents the user-connection, to the traffic arriving over an alternative VP/VC Subnetwork connection. The VP/VC Subnetwork connection that is addressed shall contain a pointer to the alternative connection.

The A- and the Z Agents respond with the result of this request (Switch To SubnetworkConnection-result).

Request:	VP/VC Connection Id	Identity assigned to the addressed VP/VC Subnetwork connection
Response:	Switch To SubnetworkConnection Result	Result of the Change-over

7.3.33 Topology Info Changes

In order that each PNO is able to determine appropriate routes for VP/VC connections (both when establishing or reconfiguring VP/VC connections) it is essential that each PNO keeps an up to date map of the topology of the network. Using the co-operative management approach, it is only necessary for the PNOs to know the topology of the inter-PNO connections, not the topology of each PNO's own network. These inter-PNO connections may be international links or they may be links between multiple PNOs located within a single country.

To be able to keep the local inter-PNO topology map up to date, each PNO shall send an indication of any changes that it makes to its inter-PNO transmission links to all the other PNOs. A similar message can be sent by a new PNO when joining the network. The details that should be sent shall include the installed capacity of the transmission link, the identity of the PNOs at each end and the status of the transmission links.

When two PNOs contract to connect together a new transmission link, an agreement is required as to which one of the PNOs will send out the topology change and assign an identity to the link.

This function has two elements that require a different set of parameters, one for handling the addition or removal of PNOs and one for handling the addition, modification and removal of inter PNO links.

For PNO addition/removal

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	PNO Subnetwork Id	Identity assigned to the PNO
	Message Status	Addition or removal of PNO
Response-	PNO Subnetwork Id	Identity of PNO sending confirmation

For Inter PNO link addition/modification/removal

It is a confirmed type of operation. The following parameters are associated with the Request and Response primitives of the function:

Request-	ATM Path Cell Rate	Capacity of the Inter-PNO link
	PNO Subnetwork Id owning the link	Identity of the PNO owning the link
	Interconnected PNO Subnetwork Id	Identity of the interconected PNO
	Message Type	Add, modify or remove inter-PNO link
	Link Status	Link active or faulty
	Inter PNO ATM Path QoS	QoS of physical link
	Inter PNO ATM Path Id	Identity of the link
Response-	PNO Subnetwork Id	Identity of PNO sending confirmation
	Inter PNO ATM Path Id	Identity of the link

8 Management information model

8.1 Introduction

NOTE 1: The visibility across the X-interface of object classes and their attributes, as well as access control information are a subject for agreements between Operators.

NOTE 2: The present model is restricted to the VP Bearer Service.

The information model described in this subclause is inherited from the ones contained in the ES 200 653 [9] and from ITU-T Recommendation I.751 [3].

For the specialization of the X Managed Object Classes the concept of Profile, as defined in the ES 200 653 [9], is used. According to this definition, to profile a managed object is to add additional normative text which restricts conditionality (e.g. specifies that a conditional package is or is not present) and adds behaviour to it.

Using this concept, the description of the Managed Object Classes is done in two steps (see figure 12):

1. A profile of the object classes of ES 200 653 [9] and ITU-T Recommendation I.751 [3] adapted for the X is defined;

2. The X Managed Object Classes are inherited from the profile defined in step 1.

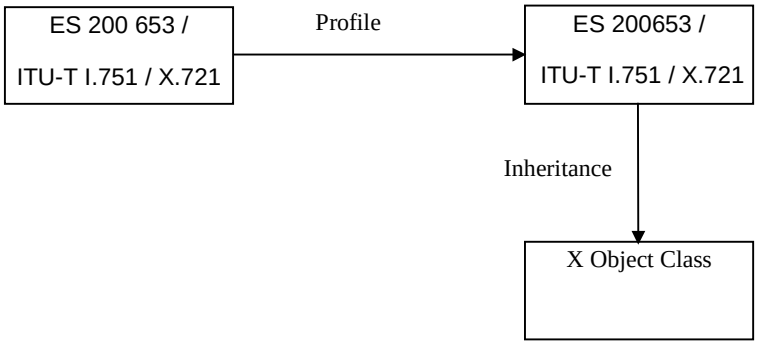

Figure 9: Methodology for the X Object Classes specialization

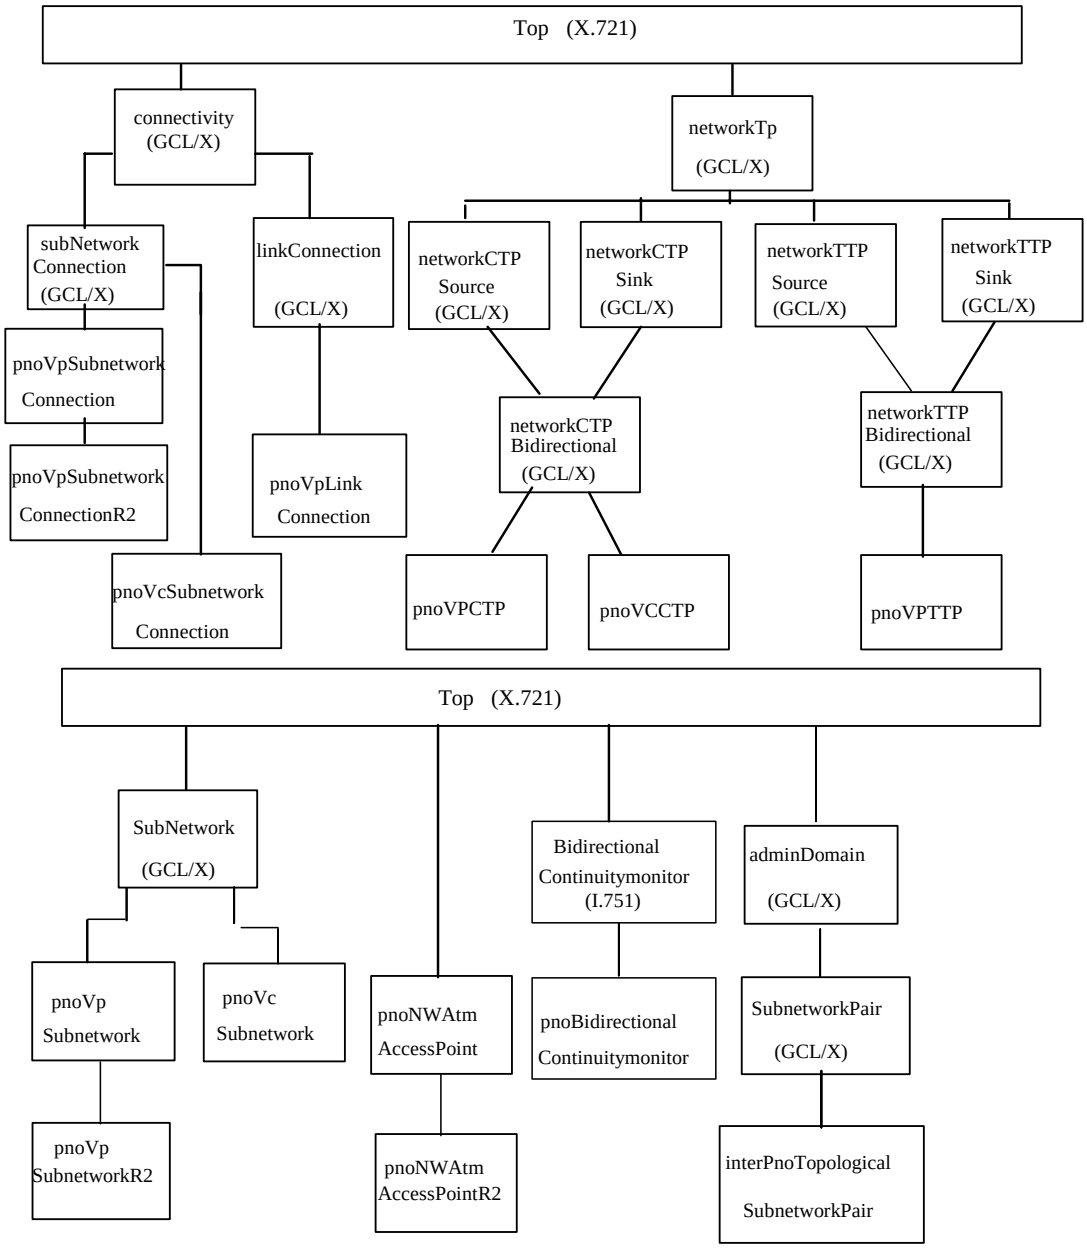
8.2 Inheritance tree



X.721: ITU-T Recommendation X.721 [2] - Definition of mnagement Information.
GCL: ES 200 653 [3] - Network level Generic Classes Library.
GCL/X: Profiled object classes from ES 200 653 [3].

NOTE: For reason of simplicity, only the objects defined in this specification are shown in the Inheritance tree.

Figure 10: Inheritance tree

8.3 Entity Relationship Diagram

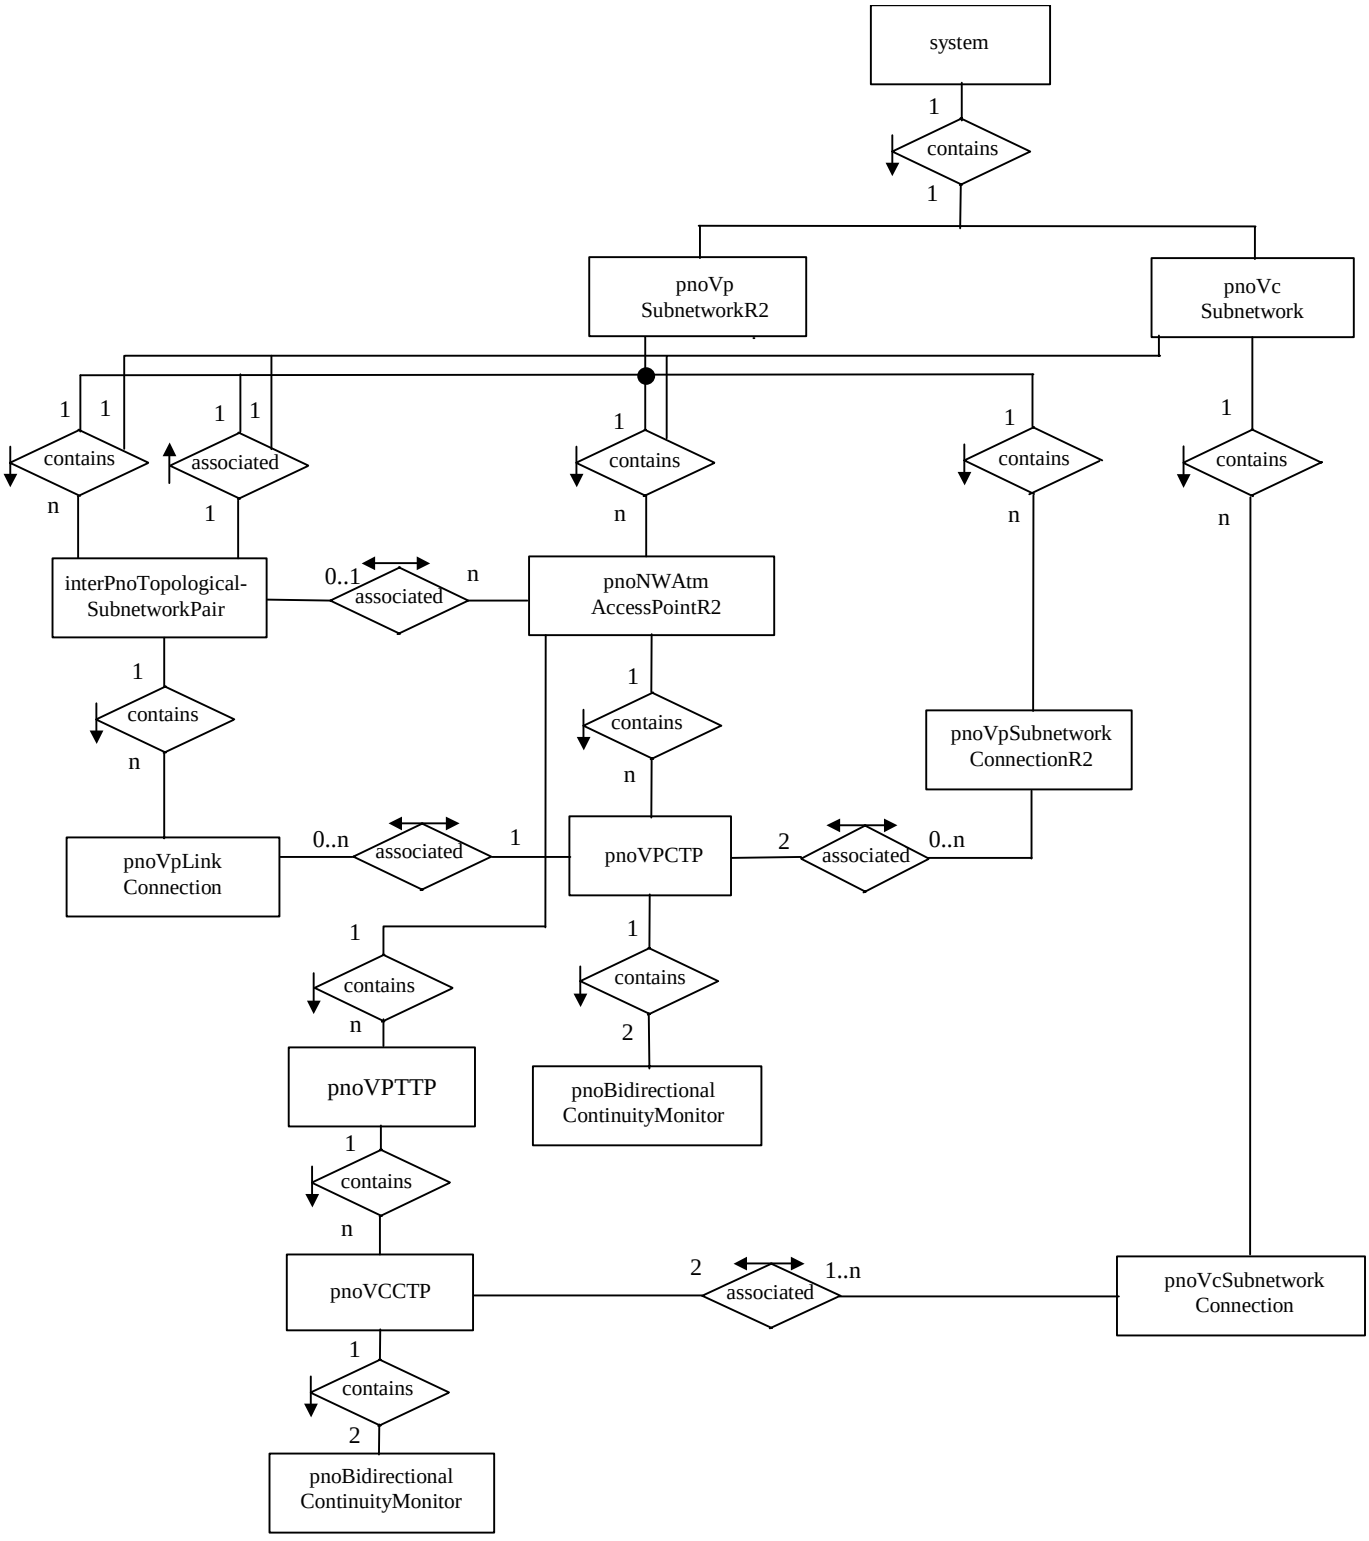


Figure 11: Entity Relationship Diagram (superclasses not shown)

8.4 ES 200 653, ITU-T Recommendations I.751 and X.721 Object Classes adapted for XIF

Subclause 8.4 specifies which conditional packages are actually used in the superclasses of the X Interface model. It is not a formal GDMO description.

8.4.1 Connectivity

PROFILE NOTE:

The attribute *signalid* will not be used in the X Managed Object Class. Its value should be set to NULL.

The conditional packages:

- assignmentStatePackage;
- availabilityStatusPackage;
- lifecycleStatePackage;
- alarmSeverityAssignmentPointerPackage;
- supportedByPackage;
- userLabelPackage; and
- qualityOfConnectivityServicePackage;

are not required for the X Managed Object Classes.

The conditional packages:

- createDeleteNotificationsPackage;
- attributeValueChangeNotificationPackage;
- stateChangeNotificationPackage;
- administrativeStatePackage;
- operationalStatePackage;
- tmnCommunicationAlarmInformationPackage; and
- zEndNWTPListPackage;

are mandatory for the X Managed Object Classes.

8.5 ATM X VP/VC Object Classes

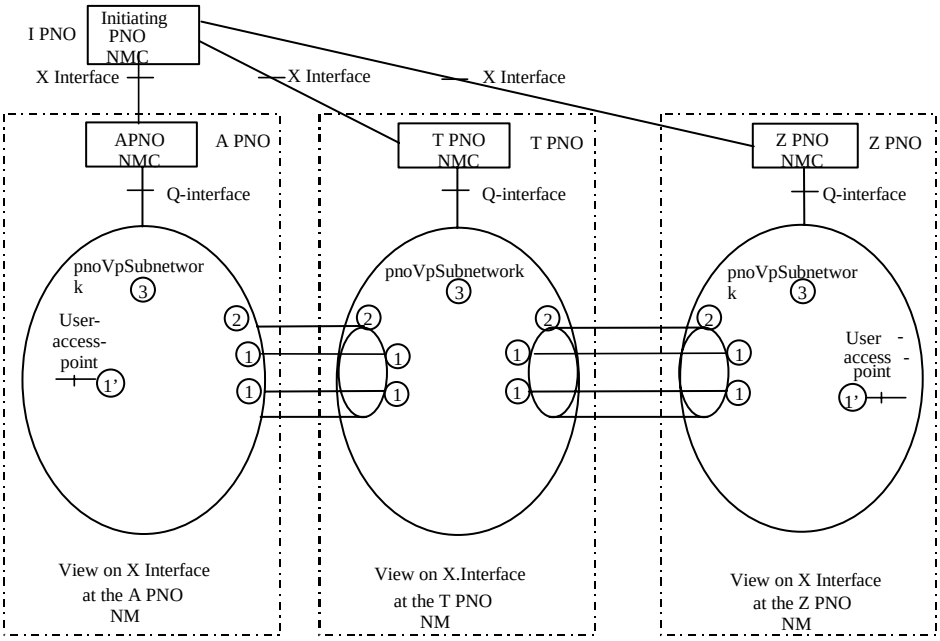
8.5.1 Introduction

The Information Model described represents the view of the ***Initiating*** PNO on the Transit and ***Z*** PNOs.

The ***Initiating*** PNO takes the role of Manager for the establishment and control of a User-to-user VP Connection. The created instances of the Objects are only managed by the ***Initiating*** PNO.

The following figures illustrate the management view from the ***Initiating*** PNO. Figure 12 represents the management view on the topological objects. Figure 13 represents the view after a User-to-user VP Connection has been setup. Figure 14 represents the view after a Vp User-to-network Connection has been setup and figure 15 the view after a Vc User-to-user connection has been setup.

In these examples the Initiating PNO and the A PNO are not the same.



Legend:
1': pnoNW AtmAccessPoint for user access (no association with (2)).

9: pnoVCCTP (VC Connection Termination Point).

Figure 15: Management View after a User-to-user VC Connection has been setup

For describing the topology in the Information Model, the A and Z Subnetworks and Access Points correspond to the name of the PNOs taken in the alphabetical order, according to what is specified in the ITU-T Recommendation M.1400 [2]. In the context of a VP/VC Connection, this notation is used independently for naming the Origin (A) and Destination (Z).

The VP Connection Id that is used for identifying uniquely the end-to-end VP Connection, is composed in the Information Model of two attributes:

- InitiatingPnoSubnetwork - Which identifies the Initiating Subnetwork;
- InitiatingVpConnectionId - Which is an identifier of the VP Connection allocated by the Initiating Subnetwork.

The same applies to a VP link Connection Id (InitiatingPnoSubnetwork, InitiatingVpConnectionId) and a VC Connection Id (InitiatingPnoSubnetwork, InitiatingVcConnectionId)

8.5.2 Connection Fragment

PNO VC Subnetwork Connection

```
pnoVcSubnetworkConnection MANAGED OBJECT CLASS
DERIVED FROM "ES 200 653 [9] ":subNetworkConnection;
CHARACTERIZED BY
pnoVcSubnetworkConnectionPackage PACKAGE
BEHAVIOUR
pnoVcSubnetworkConnectionBehaviour BEHAVIOUR
DEFINED AS
"It represents a VC connection across a PNO subnetwork. The Initiating PNO only views this
connection as a whole, with no details regarding the identification of VCCs which compose this
connection inside the PNO domain.
In order to guarantee a unique name for a pnoVcSubnetworkConnection object created as a result of
the Reserve Request, the value for its naming Attribute (SubnetworkConnectionId attribute, inherited
from the SubnetworkConnection MOC) shall be set to the concatenation of the values of the
initiatingPnoId and initiatingVcConnectionId.
The attributes initiatingPnoSubnetworkId and initiatingVcConnectionId are used by the Initiating PNO
to assign an identity to the VC Connection.
```

```
The procedure Change Reservation is performed by setting the value of the attribute
changeReservationInformation to the new value.
The procedure Cancel Change is done by replacing the value of this attribute with the default value,
which is null.
The operationalState has two possible values: Disabled or Enabled. Disabled means that a failure has
occurred in the PNO VC Subnetwork Connection. Enabled means that the VC Subnetwork Connection is in
service.
The administrativeState has two possible values: Locked and unlocked. When an instance of this
object is created, the administrativeState shall be set to locked.
A stateChangeNotification (old value = locked, new value = unlocked) will be sent by each T/Z PNO to
the initiating PNO at the beginning of an activation slot.
A stateChangeNotification (old value = unlocked, new value = locked) will be sent to the initiating
PNO at the end of an activation slot.
The procedure Activate VC Subnetwork Connection is performed by setting the administrative state to
unlocked. The procedure Deactivate VC Subnetwork Connection is performed by setting the
administrative state to locked. The activation procedure is only used if the connection is not
unlocked automatically according to the schedule, and it can also be used to allow testing outside
of the scheduled timeslots. Whenever the operationalState has the value Disabled, the activation
procedures will not succeed, and the value of the administrativeState remains locked. If the
activation procedures are used outside of the scheduled timeslots, it may be refused, for whatever
reason, in which case the value of the administrativeState also remains locked.
When an instance of pnoVcSubnetworkConnection is created this either leads to the creation of one or
two instances of pnoVCCTP, or to the usage of instances of pnoVCCTP that are already used by other
pnoVcSubnetworkConnections. In the last case there may not be overlap with the time schedule of
these Connections.
The aEndNWTPList and the zEndNWTPList point to the pnoVCCTP instances associated with the
pnoVcSubnetworkConnection.
The notifications issued by this object are sent to the Initiating PNO.
The object Creation Notification should be sent after the Succesful Reserve Result.
The notification cancelVcNetworkConnectionNotification is sent by the Z PNO to the initiating PNO.
Resilience functionality is included in the Conditional Packages kindOfResiliencePackage,
relatedSncPackage and
SwitchToSncPackage."

8.6.6 flowDirection

This package is defined in ITU-T Recommendation I.751 [3].

8.6.7 KindOfResilience

```
kindOfResiliencePackage PACKAGE
BEHAVIOUR
kindOfResiliencePackageBehaviour BEHAVIOUR
DEFINED AS
"This package indicates that the concerned Subnetworkconnection instance (the working connection)
has been provided with a resilience mechanism by assigning a protection entity to it. On detection
of an error on the working entity there will be a change-over to the traffic from the protection
entity.
Three kinds of protection can be provided:
```

```
-   Protection switching: Where, within the Subnetwork, the working connection and the protection
entity have the same end points, and the detection of an error and the following change-over to the
protection traffic occur automatically, without any network-management action.
Within protection switching the next cases are identified:
1+1 configuration: where the protection entity and the working connection convey the same traffic
simultaneously.
1:1 configuration: where the protection entity does not convey the working connection's traffic
until the change over has occurred.
Recovery with Pre-assigned Resources: Within the Subnetwork, the working connection and the
protection entity (connection) have the same end points. It is presumed that protecting resources of
some kind will be pre-assigned by the Agent. When the change-over to protected traffic has to occur,
the Agent's network management needs to take action to establish and activate the protection
connection.
Fast Rerouting: This includes more than one Subnetwork. The protection connection and the working
connection only have the A user accesspoint and the Z user accesspoint in common. In a T network
they do not have any accesspoint in common. They convey the same traffic simultaneously, and the
change-over to protection resources is performed by management.
The information held in the kindOfResilience attribute emanates from the pnoVpSubnetwork
(pnoVcSubnetwork) managed object as a result of the behaviour of the pnoVpSubnetwork
(pnoVcSubnetwork) managed object."

```

8.11.8 Reserve PNO Enhanced VpSubnetworkConnection

reservePnoEnhancedVpSubnetworkConnection ACTION
BEHAVIOUR
reservePnoEnhancedVpSubnetworkConnection-Beh BEHAVIOUR
DEFINED AS
"This action requests the involved PNO to reserve a path across its subnetwork: between a specified input point and an adjacent subnetwork if performs the T subnetwork role, between the A User and an adjacent subnetwork if it performs A subnetwork role or between a specified input port and the Z user, if it performs the Z subnetwork role. It has the same behaviour as Action reservePnoVpSubnetworkConnection, but with the additional capability to request for performance monitoring and network resilience. The acceptance or rejection of a reservation is independent of the request for performance monitoring and resilience.
The response to a rejected reservation is identical to the response for Action reservePnoVpSubnetworkConnection.
The response to an accepted reservation has the result for performance monitoring and resilience added.
If performance monitoring is requested and the reservation is accepted, the successful response will also indicate if performance monitoring is accepted (pmOK (2)), or rejected (pmNotPossible (0)).
If performance monitoring is accepted one or two other objects (i.e. pnoLCBidirectionalPerformanceMonitor & pnoSNCBidirectionalPerformanceMonitor)are created, together with the creation of a pnoVpSubnetworkConnection object.
The request for resilience can be included as an option. It is possible to ask for one type of resilience, or for a combination of types.
If resilience is requested and the reservation is accepted, the successful response will also indicate if and what types of resilience are accepted:
Protection Switching Available: protection switching capability is available for this VP connection (T) or not available (F).
Recovery Resources Assigned: whether (T) or not (F) the resources for recovery have been assigned.
fastReroutingResult: a fast re-routing is possible(T) for this VP connection, or not possible (F).
If a working Subnetwork connection has been assigned a fast re-routing protection Subnetwork connection, its attribute relatedSNC should refer to this protection connection and vice versa.
In future this action should be used instead of the reservePnoVpSubnetworkConnection action if the initiating and A / T / Z-PNO have both implemented it. The 'old' action reservePnoVpSubnetworkConnection is only implemented for backward compatibility reasons. In order to guarantee a unique name for a pnoVpSubnetworkConnection object created as a result of the Reserve Request, the value for its naming Attribute (SubnetworkConnectionId attribute inherited from the SubnetworkConnection MOC) shall be set to the concatenation of the values of the initiatingPnoId and initiatingVpConnectionId in the ASN.1 syntax of the reservePnoEnhancedVpSubnetworkConnection Action received from the Manager.";;
MODE CONFIRMED;
WITH INFORMATION SYNTAX ASN1XatmModule.ReservePnoEnhancedVp;
WITH REPLY SYNTAX ASN1XatmModule.ReservePnoEnhancedVpResult;
REGISTERED AS {xatmAction 8};

8.11.9 Reserve Pno Vc Subnetwork Connection

reservePnoVcSubnetworkConnection ACTION
BEHAVIOUR
reservePnoVcSubnetworkConnectionBehaviour BEHAVIOUR
DEFINED AS "This action requests the involved PNO to reserve a virtual channel across its subnetwork:between a specified input point and an adjacent subnetwork if performs the T subnetwork role, between the A User and an adjacent subnetwork if it performs A subnetwork role or between a specified input port and the Z user, if it performs the Z subnetwork role.
The result of this action is the acceptance or reject of the connection reservation request (regarding the start time, the stop time and eventually the periodicity requested).
If the connection reservation is rejected, the reason is returned. The meanings of the different causes for rejection are as follows:
nearEndQosNotAvailable(1): With the *nearEndPnoSubnetworkId* the Agent will find the corresponding *interPnoTopologicalSubnetworkPair* Object Instance. Within this instance, the Agent will look for the element containing the *nearEndApId* in its *listOfAtmAccessPointPairResources* attribute.
Once the Agent has found the proper element in the list, it shall check whether the forwardQoSClass and BackwardQoSClass fields in the *reserveVcInformation* can be provided according to the *atmPathQoS* field in the *listOfAtmAccessPointPairResources* attribute by the virtual path *nearEndVPCTPId*, terminating at the *nearEndAPId*.
scheduleNotAvailable(2): the agent can NOT provide the *vcConnection* with the specified *vcScheduler*.
As described in the previous cause, once the Agent has found the proper element in the *listOfAtmAccessPointPairResources* attribute, it shall check the following:
At the nearEnd side (CASE 1):
Whether the requested AtoZTrafficDescriptor of each slot of the VcScheduler fits in the current available incoming bandwidth of virtual path *nearEndVPCTPId* terminating at *nearEndAPId*. Note that the current available incoming bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on this nearEndAPId.

Whether the requested ZtoATrafficDescriptor of each slot of the VcScheduler fits in the current available outgoing bandwidth of virtual path *nearEndVPCTPId* terminating at *nearEndAPId*. Note that the current available outgoing bandwidth is internal to the agent (not visible from the XInterface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this nearEndAPId.
If the virtual path *nearEndVPCTPId*, terminating at *nearEndAPId* does not fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the scheduleNotAvailable reserve cause.
At the far End side (case 2: TRANSIT and A), the conditions to be checked are:
The requested AtoZTrafficDescriptor of each slot of the VcScheduler fits in the current available outgoing bandwidth of some virtual path terminating at the *farEndAPId* which is being checked. Note that the current available outgoing bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this farEndAPId which is being checked.
The requested ZtoATrafficDescriptor of each slot of the VcScheduler fits in the current available incoming bandwidth of some virtual path terminating at the FarEndAPId which is being checked. Note that the current available incoming bandwidth is internal to the agent (not visible from the Xcoop interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on this farEndAPId which is being checked.
If there is no element (link) in the ListOfAtmAccessPointPairResources attribute where a virtual path exists or internally can be created to fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the ScheduleNotAvailable reserve cause.
At the far End side (case 3: DESTINATION Z net), the conditions to be checked are:
The requested AtoZTrafficDescriptor of each slot of the VcScheduler fits in the current available outgoing bandwidth of some virtual path terminating at the UNI resource. Note that the current available outgoing bandwidth on this resource is internal to the agent (not visible from the Xcoop interface) and can be obtained by means of the max. outgoing bandwidth on this UNI resource on the Q3 level and the previous reservations performed on this UNI associated to the destinationAddress.
The requested ZtoATrafficDescriptor of each slot of the VcScheduler fits in the current available incoming bandwidth of some virtual path terminating at the UNI. Note that the current available incoming bandwidth is internal to the agent (not visible from the X Interface) and can be obtained by means of the max. incoming bandwidth on this UNI resource on the Q3 level and the previous reservations performed on this UNI associated to the Destination Address.
If at the UNI, associated to the Destination Address, no virtual path exists or can internally be created to fulfil the two above conditions, the Reservation Action Response will contain a negative response with the ScheduleNotAvailable reserve cause.
. **zVpiBusy(4):** the zVPi of the Vp that terminates at nearEndAPId and which is used to carry the Vc (see ReserveInformation ASN.1 definition) is already used during the specified slot times.
. **nearEndVpiOutOfRange(5):** This happens when the maximum range of subnetwork connections that can be used to on the pnoNWAccessPoint Object Instance (designed by nearEndAPId) have previously been allocated.
. **zVpiOutOfRange (6):** This happens when the maximum range of subnetwork connections on the pnoNWAccessPoint Object Instance at USER side have previously been allocated.
. **nearEndSNUnknown (7):** the nearEndPnoSubnetworkId (see ReserveInformation ASN.1 definition) is unknown.
. **farEndSNUnknown (8):** the farEndPnoSubnetworkId (see ReserveInformation ASN.1 definition) is unknown.
. **userNotAvailable (9):** it includes the following cases:
none-existent user,
user availability status with the value *notAvailable*,
user operational state with the value *disabled*,
user administrative state with the value *locked*.
. **userNotCompatible(10):** it includes the following case:
with regard to a list of Origin users which the destination user does not want to have a connection with.
. **nearEndAPisUnknown(11):** the nearEndAPId (see ReserveInformation ASN.1 definition) is unknown.
. **modeNotAvailable(12):** the mode (see ReserveInformation ASN.1 definition) is not pointToPoint(0).
. **initiatingPnoSNUnknown(13):** the PNO indicated by initiatingPnoSubnetworkId (see ReserveInformation ASN.1 definition) is unknown.
. **farEndQosNotAvailable(14):**
At the far End side (case 1: TRANSIT and A), the conditions to be checked are:
Whether the forwardQoSClass and BackwardQoSClass fields in the ReserveInformation can be provided by some virtual path terminating at the pnoNWAtmAccess Point Object Instance identified in the element being checked according to the atmPathQoS field in the ListOfAtmAccessPointPairResources attribute.
If there are no elements in the ListOfAtmAccessPointPairResources attribute that fulfil the above condition, then the Agent will respond with an unsuccessful response with the farEndQoSNotAvailable reserve cause.
At the far End side (case 2: DESTINATION Z net), the conditions to be checked are:
Whether the forwardQoSClass and BackwardQoSClass fields in the ReserveInformation can be provided by some virtual path terminating at the UNI resource according to its Quality of Service at the Q3 network level.
. **refused(15):** Used when an agent PNO refuses the reservation for whatever reason
. **nearEndVciBusy(16):** the nearEndVCCTPId (see ReserveInformation ASN.1 definition) is already used by an another vcConnection during the specified slot times.
. **zVciBusy(17):** the zVCi (see ReserveInformation ASN.1 definition) is already used during the specified slot times.

. **nearEndVciOutOfRange(18):** This happens when the maximum range of Vc subnetwork connections on the pnoNWAccessPoint Object Instance (designed by nearEndAPId) have previously been allocated.
. **zVciOutOfRange(19):** This happens when the maximum range of subnetwork connections on the pnoNWAccessPoint Object Instance at
USER side have previously been allocated.
In case of a Z PNO it is possible to define the zVPi and zVCi within the reserveInformation. If this requested zVPi or
zVCi cannot be provided, the reserveCause zVpiBusy or zVciBusy is also to be responded.
If the connection reservation is accepted, a pnoVcSubnetworkConnection object is created."

8.11.10 Reserve PNO VP Link Connection

reservePnoVpLinkConnection ACTION
BEHAVIOUR
reservePnoVpLinkConnectionBehaviour BEHAVIOUR
DEFINED AS "This action reqests a PNO to make a VP Link Connection reservation across an 'Inter-Pno link' with an adjacent PNO.
It is requested by the Initiating PNO. The result of this action is the acceptance or reject of the connection reservation request (regarding the start time, the stop time and eventually the periodicity requested).
If the *adjacentPnoSubnetworkId* (see ASN.1 definition) is specified in the request, the Agent will look if there is a corresponding *interPnoTopologicalSubnetworkPair* Object Instance and if this instance contains a suitable link. As seen from the Agent here the direction 'aToZ' in the request is in the direction of the adjacent subnetwork.
If the SEQUENCE *'nearEndAPId, nearEndVPCTPId, nearEndPnoSubnetworkId'* (see ASN.1 definition) is specified in the request, the link has already been chosen by the I PNO and the Agent will check if it can provide the connection. As seen from the Agent, here the direction '*aToZ*' in the request is in the direction of the Agents' own subnetwork.
If the connection reservation is rejected, the reason is returned. The meanings of the different causes for rejection are as follows:
linkQosNotAvailable(1): The requested *aToZQoSC*lass and *zToAQoSClass* in the reserveLinkInformation can NOT be provided by the Link (*atmPathQoS* field in the *listOfAtmAccessPointPairResources* attribute).
linkScheduleNotAvailable(2): the agent can NOT provide the requested *vpLinkConnection* with the specified *vpScheduler*.
The Agent shall check the following:
(If the SEQUENCE 'nearEndAPId, nearEndVPCTPId, nearEndPnoSubnetworkId' is specified in the request):
('incoming' and 'outgoing' are with regard to the Agents' subnetwork)
Whether the requested AtoZTrafficDescriptor of each slot of the VpScheduler fits in the current available incoming bandwidth. Note that the current available incoming bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on the nearEndAPId.
Whether the requested ZtoATrafficDescriptor of each slot of the VpScheduler fits in the current available outgoing bandwidth. Note that the current available outgoing bandwidth is internal to the agent (not visible from the XInterface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this nearEndAPId.
If the nearEndAPId does not fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the scheduleNotAvailable reserve cause.
(If *adjacentPnoSubnetworkId* is specified in the request):
('incoming' and 'outgoing' are with regard to the Agents' subnetwork)
The requested AtoZTrafficDescriptor of each slot of the VpScheduler fits in the current available outgoing bandwidth for the link which is being checked. Note that the current available outgoing bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this link which is being checked.
The requested ZtoATrafficDescriptor of each slot of the VpScheduler fits in the current available incoming bandwidth for the link which is being checked. Note that the current available incoming bandwidth is internal to the agent (not visible from the Xcoop interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on this farrEndAPId which is being checked.
If there is no element (link) in the ListOfAtmAccessPointPairResources attribute to fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the ScheduleNotAvailable reserve cause.
. **nearEndVpiBusy(3):** requested nearEndVPCTPId in the reserveLinkInformation (see ASN.1 definition) is already used by an another vpConnection during the specified slot times.
. **nearEndVpiOutOfRange(4):** requested nearEndVPCTPId in the reserveLinkInformation (see ASN.1 definition) is outside of the VPI-range as determined by the involved pnoNWAccessPoint Object Instance.
. **nearEndSNUnknown(5):** nearEndPnoSubnetworkId (see ReserveLinkInformation ASN.1 definition) is unknown.
. **nearEndAPisUnknown(6):** nearEndAPId (see ReserveLinkInformation ASN.1 definition) is unknown.
. **modeNotAvailable(7):** mode (see ReserveLinkInformation ASN.1 definition) is not pointToPoint(0).

. **initiatingPnoSNUnknown(8):** PNO indicated by initiatingPnoSubnetworkId (see ReserveLinkInformation ASN.1 definition) is unknown.
. **refused(9):** used when an agent PNO refuses the reservation for whatever reason
If the connection reservation is accepted, a pnoVpLinkConnection object is created."

8.11.11 Reserve PNO VP Subnetwork Connection

reservePnoVpSubnetworkConnection ACTION
BEHAVIOUR
reservePnoVpSubnetworkConnectionBehaviour BEHAVIOUR
DEFINED AS "This action requests the involved PNO to reserve a path across its subnetwork: between a specified input point and an adjacent subnetwork if performs the T subnetwork role, between the A User and an adjacent subnetwork if it performs A subnetwork role or between a specified input port and the Z user, if it performs the Z subnetwork role. The result of this action is the acceptance or reject of the connection reservation request (regarding the start time, the stop time and eventually the periodicity requested).
If the connection reservation is rejected, the reason is returned. The meanings of the different causes for rejection are as follows:
. nearEndQosNotAvailable(1): With the *nearEndPnoSubnetworkId* the Agent will find the corresponding *interPnoTopologicalSubnetworkPair* Object Instance. Within this instance, the Agent will look for the element containing the nearEndApId in its *listOfAtmAccessPointPairResources* attribute.
Once the Agent has found the proper element in the list, it shall check whether the forwardQoSClass and BackwardQoSClass fields in the *reserveInformation* can be provided by the *nearEndAPId* according to the *atmPathQoS* field in the *listOfAtmAccessPointPairResources* attribute.
. scheduleNotAvailable(2): the agent can NOT provide the vpConnection with the specified vpScheduler.
As described in the previous cause, once the Agent has found the proper element in the *listOfAtmAccessPointPairResources* attribute, it shall check the following:
At the nearEnd side (CASE 1):
Whether the requested AtoZTrafficDescriptor of each slot of the VpScheduler fits in the current available incoming bandwidth. Note that the current available incoming bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on this nearEndAPId.
Whether the requested ZtoATrafficDescriptor of each slot of the VpScheduler fits in the current available outgoing bandwidth. Note that the current available outgoing bandwidth is internal to the agent (not visible from the XInterface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this nearEndAPId.
If the nearEndAPId does not fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the scheduleNotAvailable reserve cause.
At the far End side (case 2: TRANSIT and A), the conditions to be checked are:
The requested AtoZTrafficDescriptor of each slot of the VpScheduler fits in the current available outgoing bandwidth on the FarEndAPId which is being checked. Note that the current available outgoing bandwidth is internal to the agent (not visible from the X Interface) and shall be obtained by means of the max. outgoing bandwidth and the previous reservations performed on this farEndAPId which is being checked.
The requested ZtoATrafficDescriptor of each slot of the VpScheduler fits in the current available incoming bandwidth on the FarEndAPId which is being checked. Note that the current available incoming bandwidth is internal to the agent (not visible from the Xcoop interface) and shall be obtained by means of the max. incoming bandwidth and the previous reservations performed on this farrEndAPId which is being checked.
If there is no element (link) in the ListOfAtmAccessPointPairResources attribute to fulfil the two above conditions, the Reservation Action Response will contain an unsuccessful response with the ScheduleNotAvailable reserve cause.
At the far End side (case 3: DESTINATION Z net), the conditions to be checked are:
The requested AtoZTrafficDescriptor of each slot of the VpScheduler fits in the current available outgoing bandwidth on the UNI resource. Note that the current available outgoing bandwidth on this resource is internal to the agent (not visible from the Xcoop interface) and can be obtained by means of the max. outgoing bandwidth on this UNI resource on the Q3 level and the previous reservations performed on this UNI associated to the destinationAddress.
The requested ZtoATrafficDescriptor of each slot of the VpScheduler fits in the current available incoming bandwidth on the UNI. Note that the current available incoming bandwidth is internal to the agent (not visible from the X Interface) and can be obtained by means of the max. incoming bandwidth on this UNI resource on the Q3 level and the previous reservations performed on this UNI associated to the Destination Address.
If the UNI associated to the Destination Address does not fulfil the two above conditions, the Reservation Action Response will contain a negative response with the ScheduleNotAvailable reserve cause.
. **nearEndVpiBusy(3):** the nearEndVPCTPId (see ReserveInformation ASN.1 definition) is already used by an another vpConnection during the specified slot times.
. **zVpiBusy(4):** the zVPi (see ReserveInformation ASN.1 definition) is already used during the specified slot times.
. **nearEndVpiOutOfRange(5):** This happens when the maximum range of subnetwork connections on the pnoNWAccessPoint Object Instance (designed by nearEndAPId) have previously been allocated.

```
. zVpiOutOfRange(6): This happens when the maximum range of subnetwork connections on the
pnoNWAccessPoint Object Instance at
 USER side have previously been allocated.
. nearEndSNUnknown(7): the nearEndPnoSubnetworkId (see ReserveInformation ASN.1 definition) is
unknown.
. farEndSNUnknown(8): the farEndPnoSubnetworkId (see ReserveInformation ASN.1 definition) is
unknown.
. userNotAvailable(9): it includes the following cases:
none-existant user,
user availability status with the value notAvailable,
user operational state with the value disabled,
user administrative state with the value locked.
. userNotCompatible(10): it includes the following case:
with regard to a list of Origin users which the destination user does not want to have any
connection with.
. nearEndAPisUnknown(11): the nearEndAPId (see ReserveInformation ASN.1 definition) is unknown.
. modeNotAvailable(12): the mode (see ReserveInformation ASN.1 definition) is not pointToPoint(0).
. initiatingPnoSNUnknown(13): the PNO indicated by initiatingPnoSubnetworkId (see ReserveInformation
ASN.1 definition) is unknown.
. farEndQosNotAvailable(14):
At the far End side (case 1: TRANSIT and A), the conditions to be checked are:
Whether the forwardQoSClass and BackwardQoSClass fields in the ReserveInformation can be provided by
the pnoNWAtmAccess Point Object Instance identified in the element being checked according to the
atmPathQoS field in the ListOfAtmAccessPointPairResources attribute.
If there are no elements in the ListOfAtmAccessPointPairResources attribute that fulfil the above
condition, then the Agent will respond with an unsuccessful response with the farEndQoSNotAvailable
reserve cause.
At the far End side (case 2: DESTINATION Z net), the conditions to be checked are:
Whether the forwardQoSClass and BackwardQoSClass fields in the ReserveInformation can be provided by
the UNI resource according to its Quality of Service at the Q3 network level.
. refused(15): Used when an agent PNO refuses the reservation for whatever reason
In case of a Z PNO it is possible to define the zVPi within the reserveInformation. If this
requested zVPi can not be provided, the reserveCause zVpiBusy is also to be responded.
If the connection reservation is accepted, a pnoVpSubnetworkConnection object is created."

    SUBORDINATE OBJECT CLASS pnoVPTTP;
    NAMED BY
    SUPERIOR OBJECT CLASS pnoNWAtmAccessPointR2;
    WITH ATTRIBUTE "ITU-T Recommendation M.3100 [1] (1995)": tTPId;
BEHAVIOUR
pnoVPTTP-pnoNWAtmAccessPointR2Behaviour BEHAVIOUR
DEFINED AS
"A pnoVPTTP object instance is created by:
The reservePnoVpLinkConnection action, when the initiating PNO wants the VP link connection to serve
as a trail for User-to-user VCCs who are also to be reserved over the X-Interface.
The reservePnoVcSubnetworkConnection Action when an internal VpLinkconnection is created to carry
the VCC over the physical link between two subnetworks.
The object instance is deleted by the action releasePnoVcSubnetworkConnection or
releasePnoVpLinkConnection when there are no other VCs left that use the VP trail."

Annex A (informative): About the influence of timers on the X-interface communication

Over the X-interface, the response time to a reserve-request can be very long, due to the fact that some agents might need a long time to carry out the CMISE-indication. It is obvious that a manager cannot wait forever for the result of his request.

This annex describes how a manager can cope with this by using a timer.

As neither CMIP nor the rest of the OSI-stack have timers defined that specify the maximum responsetime, the application (the Manager or the Agent) will have to specify it.

Most applications will automatically end an association after a relatively short time.

To watch long response-times, the Manager can apply an additional internal timer (internal = "not visible on the X-interface").

So, the following cases can be considered. (a, b, c, d):

a) The response-time is relatively short ("real time"), no communications-error:

   - this is the normal case that is covered by the present model.

b) The response-time is usually relatively short, but a communication-error causes the association (connection) to end, during the time that the manager is waiting for the result of his request.

   - The Agent cannot use its CMISE response to the original CMISE indication because, due to the lost association, the invocation of the response is now meaningless. The Manager should wait (for a relatively short time) and then there will be two possibilities:

   1) The reservePnoVpSubnetworkConnection has a successfulResult: The Agent uses the object-creation Notification. The Agent is the invoker of a new association that is used for transmitting the Notification.

   2) The reservePnoVpSubnetworkConnection has an unsuccessfulResult: There is no Notification for the agent to send. The manager, however, is aware of the situation (the association has ended), so he can send the same reserveRequest again in order to get the unsuccessfulResult as a response.

      - (Or, first the Manager can do a GET on pnoVpSubnetworkConnection. If it does not see the Instance it can send the same reserveRequest again).

Case b) is also covered by the present model.

c) The response-time is long, no communication-error. This also addresses General Requirements G.7 and G.5:

   1) The internal "Manager-timer" watches the response-time. If the time is passed, the manager can act as if no request has been made at all and bring back the system to the "pre-request" state. To notify the Agent that it gave up waiting the Manager has to send a "releasePnoVpSubnetworkConnection" Action.

d) The response-time is long and a communications-error causes the association to end (or the manager ends it to reduce costs). There are two possibilities:

   1) The reservePnoVpSubnetworkConnection has a successfulResult within the waiting-time of the manager: The agent uses the object-creation Notification. The Agent is the invoker of a new association that is used for transmitting the Notification.

   2) The reservePnoVpSubnetworkConnection has an unsuccessfulResult: There is no Notification for the agent to send. The manager waits until the time has passed (remember that the waiting has to end some time), it brings back his system in the "pre-request" state and, to be certain, sends a "releasePnoVpSubnetworkConnection" Action to the Agent.

Annex B (informative): Security Aspects

With regard to Access Control as seen from a particular Agent's view the next table should be considered.

Table B.1

Objectclass	Access to the instances in accordance with the GDMO definition of the OC for:	Notifications are sent to:
PnoVcSubnetwork	All other PNOs.	All other PNOs
PnoVpSubnetwork	All other PNOs.	All other PNOs
PnoVpSubnetworkR2	All other PNOs.	All other PNOs.
PnoVcSubnetworkConnection (note 1)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)
PnoVpLinkConnection (note 1)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)
PnoVpSubnetworkConnection (note 1)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)
PnoVpSubnetworkConnectionR2 (note 1)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)	Only the PNO that requested the creation of the instances involved. (Initiating PNO)
PnoNWAtmAccessPoint (note 2)	All other PNOs.	All other PNOs.
PnoNWAtmAccessPointR2 (note 2)	All other PNOs.	All other PNOs
InterPnoTopologicalSubnetworkPair	All other PNOs.	All other PNOs
PnoVCCTP	Only those PNOs that requested a pnoVcSubnetworkConnection that points to the pnoVCCTP.	Only those PNOs that requested a pnoVcSubnetworkConnection that points to the pnoVCCTP.
PnoVPCTP	Only those PNOs that requested a pnoVpSubnetworkConnection /LinkConnection that points to the pnoVPCTP.	Only those PNOs that requested a pnoVpSubnetworkConnection/Link Connection that points to the pnoVPCTP.
pnoVPTTP	The PNOs that use it as a "Server-TTP" for VC connections.	The PNOs that use it as a "Server-TTP" for VC connections.
NOTE 1: A Manager, trying to read all Instances of pnoVpSubnetworkConnection shall only get the Instances in which he is the initiating PNO. Whether his attempt to read all instances should be registered is a matter for "Security Management". NOTE 2: Z nets: After a successful reserve-request has been made in its subnet, an Agent-PNO is free to decide if it wants to create an instance of pnoNWAtmAccessPoint for the user-side of the connection.		

In general, the usage of a "closed user group" is suggested; only PNOs that are in the closed user group are allowed to set up an association with the appropriate PNO.

How this Access Control is implemented is not within the scope of the present document.

Annex C (informative): ATM VP/VC Resilience

A PNO playing the Initiator role should be able to choose between 4 different ways of protecting a User to user VP/VC connection, depending on the way the protection is performed. These are:

- Intra-Subnetwork Protection Switching;
- Intra Subnetwork Recovery;
- A-to-Z Fast Re-routing;
- VP/VC Reconfiguration.

It should be possible to apply these four methods of VP/VC protection independently or in combination.

The detailed explanation of each of the four definitions listed above is achieved with the support of a figure representing each different situation. The topology map that will be used as a basis for the examples is provided in figure C.1, in which no connections are depicted.

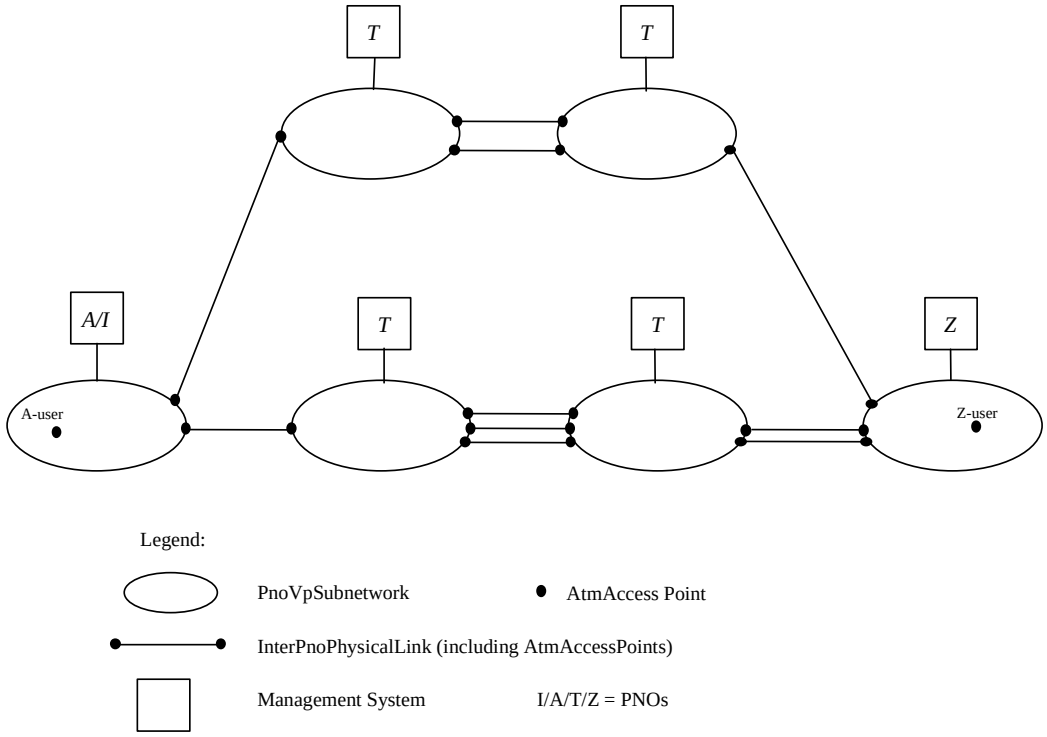

Figure C.1: General Topology map with User to user and VP/VC Subnetwork connections omitted

ITU-T Recommendation I.630 [6] requires that a connection is protected by one or more other connections. Therefore two types of connections, 'working' and 'protection' - were defined. The working connection is assigned to transport the traffic, whereas the protection connection is assigned to transport the traffic when protection is active. For Intra-Subnetwork Protection Switching, the configurations 1+1 and 1:1 were considered [6]. The (1:1) concept is also applicable to 'Fast Re-routing'. The use of simultaneous transmission of traffic on working and protection VP/VC connections and the availability of rapid switching to the protection connection in the event of a failure to allow Fast Re-routing is described later in this subclause.

Intra-Subnetwork Protection Switching

Protection switching is an event which may be activated by a PNO (within its own Subnetwork) supporting a VP/VC Subnetwork connection in response to an alarm generated by a network entity. The requirement is for the network elements to be able to select (i.e. switch to) dedicated and pre-assigned - capacity, which is protecting primary resources involved in the provision of the VP/VC, on receipt of the alarm.

The ATM Protection Switching can be a 1+1 or a 1:1 configuration. The (1+1) configuration conveys the protected traffic simultaneously on the working and protection connection. By contrast, the protection connection does not simultaneously convey protected traffic in the (1:1) configuration, but relies on traffic being rapidly switched onto it if the working connection fails.

Further, a requirement for protection switching is that it can be activated without the involvement of a manual network management function. Accordingly, it is a function that shall be automatic and very rapid.

Intra-Subnetwork Protection Switching does not include Protection Switching of IPPL.

The I-PNO will choose the Intra-Subnetwork Protection Switching option when it is sufficient to protect a connection against faults/performance degradations that occur within the Subnetwork of an A/T or Z-PNO.

The PNO experiencing the fault performs Protection Switching on its Subnetwork connection, keeping the endpoints unchanged, as represented in the figure C.2.

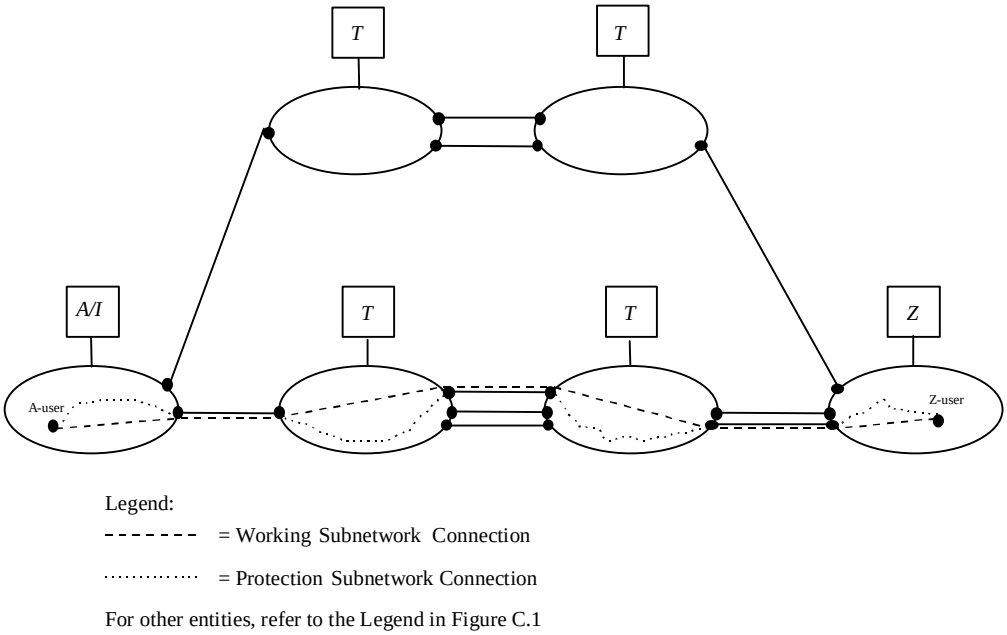

Figure C.2: Intra Subnetwork protection Switching

The PNO experiencing the fault will have to notify the I-PNO that he has successfully performed the protection switching on his part of the connection.

Intra-Subnetwork Recovery

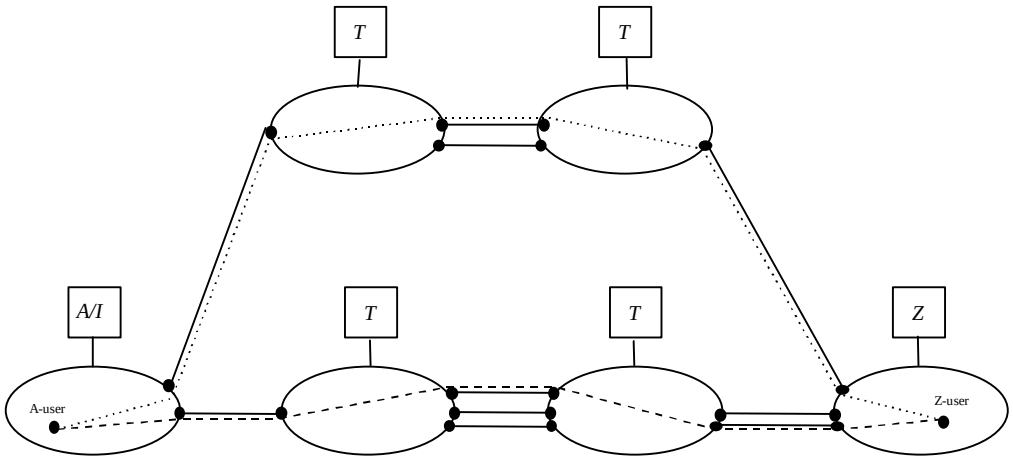
Recovery means a change-over to spare or back-up resources resulting from an internal network management action of an A, T or Z-PNO, which successfully restores an existing VP or VC to an operational state in a short time (e.g. seconds or minutes). A recovery action may follow a failed attempt to overcome a network resource failure by protection switching, or recovery action could be the only strategy implemented to protect a connection.

In the latter case, when a PNO experiences a network resource failure, it should start the recovery process and immediately send out the proper notification to the I-PNO.

The out-of-service time affecting the connection depends on each individual case and on how the recovery processes are implemented. In all cases, the user will experience service failure.

A-to-Z Fast Re-routing

For highly guaranteed connections the I-PNO might require a global (A User to Z User) resilience mechanism, that protects against both intra-PNO and inter-PNO failures. For this requirement, the End-to-end connection needs to be duplicated on a completely different route, especially on different inter-PNO links and needs to be continuously active during the lifetime of the protected connection, as depicted in figure C.3.



Legend:

= Working Connection

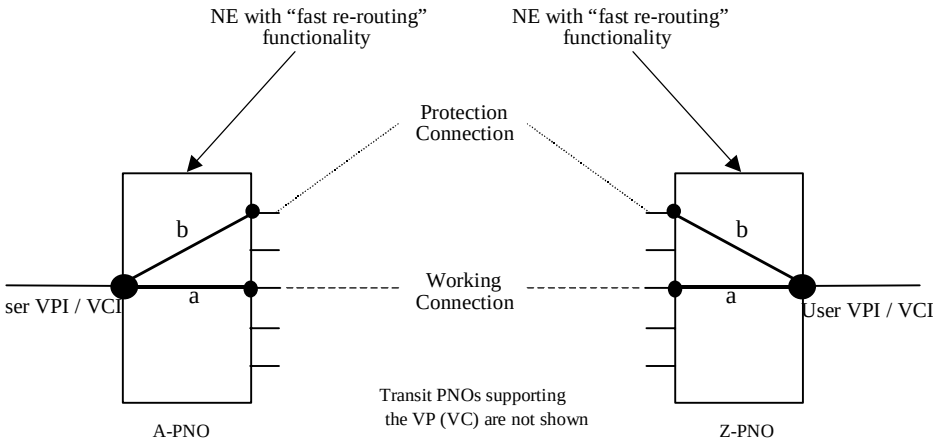
= Protection Connection

For other entities, refer to the Legend in Figure C.1

Figure C.3: A to Z Fast Re-routing

If a failure occurs, the traffic will need to be routed, as soon as possible, from the working to the protection connection. This mechanism is called 'Fast Re-routing'. Some cell loss associated with the failure is to be expected however.

Figure C.4 depicts the basic mechanism where the traffic from the A-user connection is simultaneously routed over working connection 'a' and protection connection 'b' from the designated network element inside the A-PNO's Subnetwork. Incoming traffic at the Z-PNO's Subnetwork should be taken from the 'a' connection but may be switched to the 'b' connection on receipt of the appropriate notification from the I-PNO.



Legend:

NE:	Network Element		
VP	Virtual Path	VC	Virtual Channel
VPI	Virtual Path Identifier	VCI	Virtual Channel Identifier

Figure C.4: Fast Re-routing at A- or Z-Subnetwork

The processes to invoke Fast Re-routing are as follows.

If a PNO detects a failure in its domain it will send a notification to the I-PNO. The I-PNO will request the A-PNO and the Z-PNO to take the traffic arriving from the alternative route (i.e. to switch from working connection (a) to protection connection (b))

VP Reconfiguration

Here, the I-PNO does not reserve an alternative path in advance, nor asks for special protected connections.

After receiving the notification from a PNO that a failure has occurred in its Subnetwork, the I-PNO has the choice to wait for the notification that the failure has been cleared or to start to set-up an alternative route for the affected connection, using the reservation-procedures.

Annex D (informative): Mapping between Management Functions, CMISE Services and ObjectClasses

Table D.1

FUNCTIONS	CMISE SERVICES	OBJECT CLASSES / Operations
Activate Bidir. Cont. Mon. Source for Continuity Check	M-ACTION	PnoBidirectionalContinuityMonitor/ controlContinuity Check Action
Activate Change	M-ACTION	PnoVpSubnetworkConnection(+R2), pnoVcSubnetworkConnection, pnoVpLinkConnection / activateChange Action

VP Subnetwork Connection Activation Notification (the administrativeState is automatically changed by the agent PNO)	M-EVENT-REPORT	PnoVpSubnetworkConnection(+R2) / stateChangeNotification

Annex E (informative): Mapping parameters VpQosClass and VcQosClass to ATM QoS

In the VP/VC reserve request a certain QoS is included. This parameter is represented by an INTEGER value (0..99). Since ATM QoS is described by various performance parameters (ITU-T Recommendation I.356 [14]), a QoS table should be agreed between the PNOs that use the X-Interface. This table should map integer values to specific combinations of values of the several QoS performance parameters. (Also, see [8]).

For a T subnetwork, the requested values of the QoS performance parameters should refer to the part of the connection that goes across the Agent's subnetwork and the "far-end" link.

For an A subnetwork, the requested values of the QoS performance parameters should refer to the part of the connection that originates at the A user and goes across the Agent's subnetwork and the "far-end" link.

For a Z subnetwork, the requested values of the QoS performance parameters should refer to the part of the connection that goes across the Agent's subnetwork and terminates at the Z user.

If possible, the requested values of the QoS performance parameters could be split into a subnetwork connection (SNC) part and a link connection (LC) part.

Figure E1 shows an example of a table, with no values filled in. It is possible that not all performance parameters have to be used.

QoS Parameter	**CLR**		**CTD**		**CMR**		**CDV**		**CER**		**SECBR**	
INT	SNC	LC	SNC	LC	SNC	LC	SNC	LC	SNC	LC	SNC	LC
1												
2												
3												
etc												

Figure E.1: A table to map integer values to QoS performance parameter values

Annex F (informative): Future Organizational Models

This clause describes different organizational models, which might be used in future for establishing X-interface relationships between PNOs. These models should be flexible enough to accommodate many different combinations of interconnected PNOs. However, the choice of which model to use will be determined by agreements between the participating PNOs. The implications that the future organizational models will have on the X-interface model need to be further studied.

Since there are two extreme organizational models and a mixture of those extremes, there can be (at least) three different organizations for a particular VP connection (if there are more than three PNOs involved). These three organizations are shown in figure F.1:

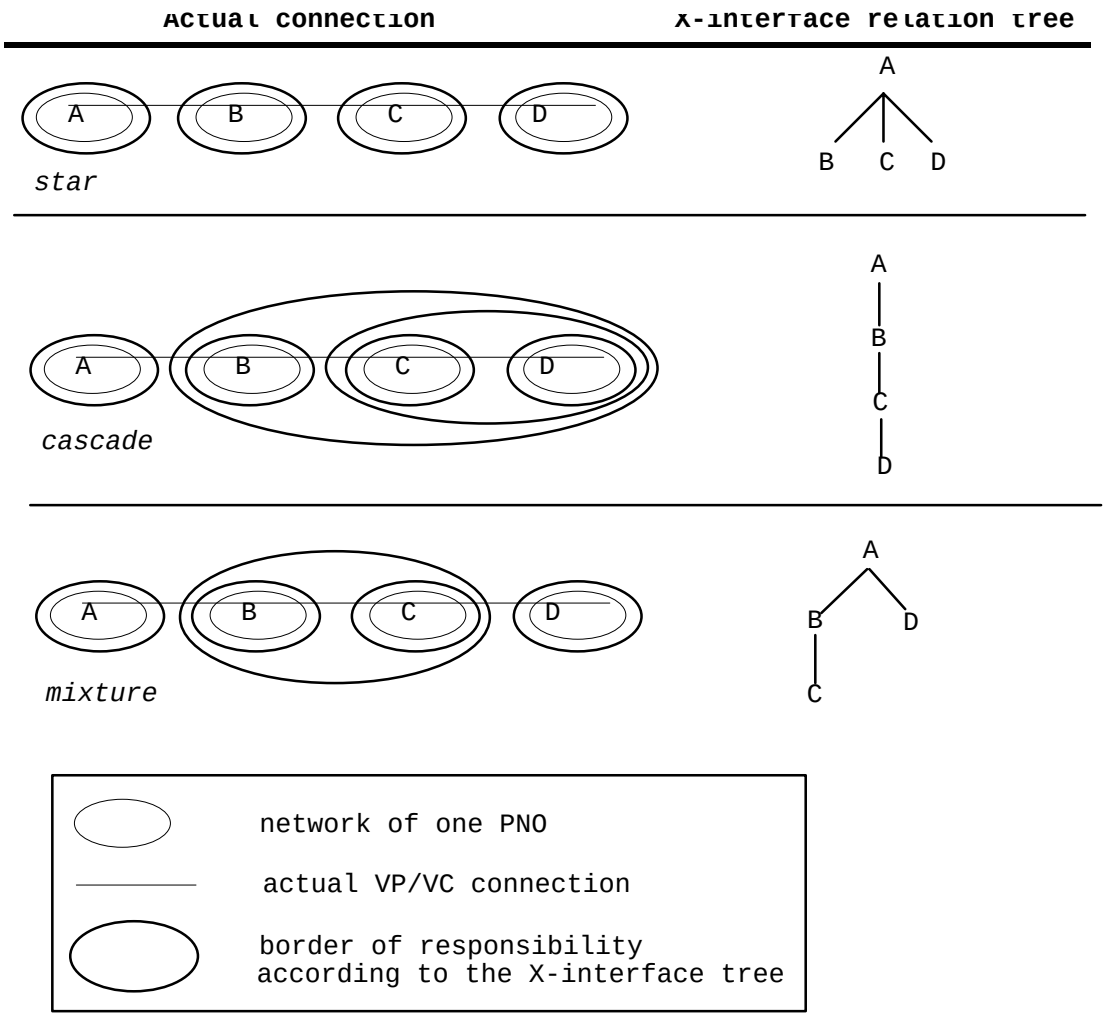

Figure F.1: Organizational models

In the *Star* organization as exemplified in the figure above, PNO A uses the X-interface relation with all the PNOs involved. This means that PNO A has full responsibility for the entire connection and all the other PNOs are only responsible for their own network towards PNO A.

In the *Cascade* organization in this example, PNO A delegates the responsibility for the VP connection outside its network to B; on its turn, B delegates the responsibility for the VP connection outside its network to C, etc. This means that PNO A has responsibility for the entire connection; B, however, is **towards PNO A** not only responsible for its own network but also for this particular VP connection throughout the networks of PNO C and D; on its turn, PNO C is **towards PNO B** not only responsible for its own network but also for this particular VP connection throughout the networks of PNO D, etc.

In the "*Mixture"* organization in this particular example (other examples are also possible), PNO A uses an X-interface relationship with both PNO B and PNO D (i.e. a star organization). However, PNO B involves PNO C to reach PNO D. Therefore PNO B is responsible towards PNO A for both its network and the connection throughout the network of PNO C (i.e. cascade organization).

The Consumer/Provider roles, introduced in subclause 4.2, are reflected by the X-interface tree: in the Star example above, PNO A has a Consumer role, whereas PNO B, C and D have a Provider role. In the Cascade example above, PNO A has a Consumer role, PNO B has a Provider role towards PNO A,and a Consumer role towards PNO C, etc. In the Mixture example PNO A has a Consumer role, whereas PNO B and D have a Provider role towards PNO A; PNO B also has a Consumer role towards PNO C; PNO C has Provider role towards PNO B. Concluding: if a PNOx is directly above a PNOy in the X-interface tree, then PNOx has a Consumer role, and PNOy has a Provider role.

F.1 Responsibility of PNOs regarding a VP/VC connection

This clause denotes which responsibility is required from each PNO involved a particular VP/VC connection. The following rules apply:

- **Rule 1:** A PNO is responsible for the management of a particular VPC/VCC within its own PNO Subnetwork and the part of this VPC/VCC throughout all the PNO Subnetworks below it in the X-interface tree for this connection (i.e. it is responsible for its subnetwork view). It is responsible for this part of the connection towards its parent in the X-interface tree (if not being the Initiating PNO, which is responsible towards the connection customer).

- **Rule 2:** Besides the responsibility in rule 1, a PNO is also responsible for the ATM Connection over the physical connection from its PNO Subnetwork to the next PNO Subnetwork on the route of a VP/VCC (seen from the A towards the Z).

- **Rule 3:** A PNO can delegate part of its management tasks outside its own PNO subnetwork to one or more other PNOs (these PNOs have a Provider role). This delegation consists of maintaining a requested Quality of Service for this particular connection and reporting about it (via the X-interface to its parent in the X interface tree).

F.1.1 Examples of application of the responsibility rules

The responsibility rules described in clause F.1 are illustrated by the following scenario description. The scenario starts with the existence of a particular VPC/VCC between PNOs A and C via B and a particular X-interface relation tree. The scenario describes the occurrence of 4 failures that need management action; each of them is described in one step of the scenario description. The 4 steps are an example of part of the life cycle of this particular VPC/VCC and take place in sequence. The scenario description is illustrated in figures F.2 through F.5.

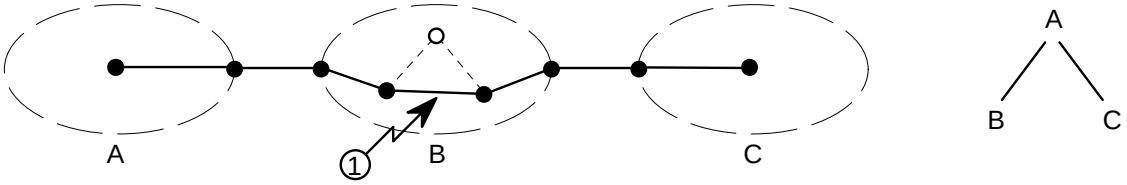

Figure F.2: Step 1 of example scenario

Step 1: A fault has occurred in the VPSC / VCSC within the PNO subnetwork of PNO B. PNO B reports to its Consumer PNO (PNO A) about the failure and indicates that the failure is recoverable. PNO B starts the reconfiguration process and ensures that alarms are suppressed. After reconfiguration has been successfully completed, PNO B reports this to its Consumer.

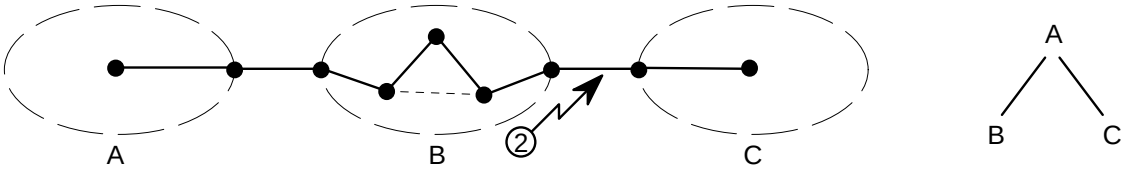

Figure F.3: Step 2 of example scenario

Step 2: A fault has occurred in the inter-PNO VP / VCLC between PNO B and PNO C. Since this is the outgoing inter-PNO VP / VCLC of the PNO subnetwork of PNO B, PNO B is responsible for reporting this failure to its Consumer PNO (PNO A). PNO B reports the failure to PNO A and indicates that it can recover the failure. PNO B performs recovery on the faulty inter-PNO VP/VC LC and notifies its Consumer about this and about the Id of the new physical link in the connection and takes action to suppress associated alarms.

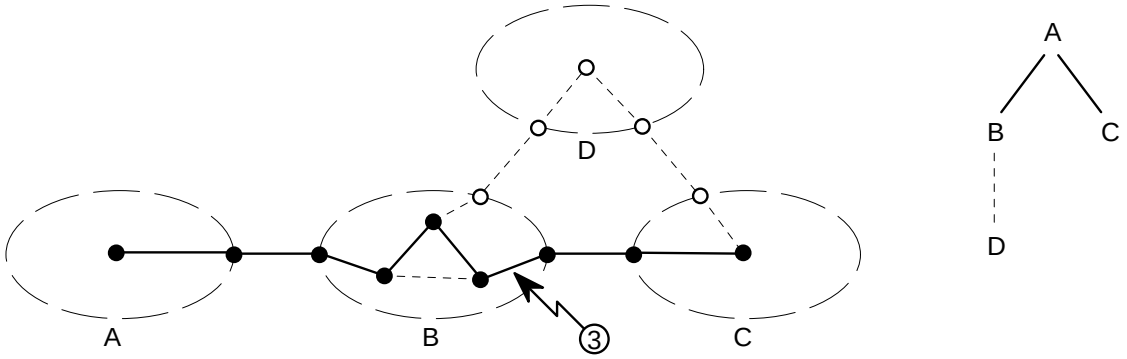

Figure F.4: Step 3 of example scenario

Step 3: A fault has occurred in the VPSC / VCSC within the PNO subnetwork of PNO B. PNO B reports this to PNO A. Let us assume that protection switching and reconfiguration of the VPSC / VCSC within the PNO subnetwork of PNO B are not possible. PNO B, however, believes that it can reroute the VPSC / VCSC via another PNO and indicates this to PNO A. PNO B starts a reconfiguration process, in which it reroutes the VPSC / VCSC via PNO D, and notifies its Consumer about this (for suppressing alarms). PNO B reserves a VPSC / VCSC within the PNO subnetwork of PNO D. After successful reservation, PNO D reports back to PNO B (its Consumer) the Id of the physical link between PNO D and PNO C. After reconfiguration has been completed, PNO B reports successful reconfiguration to its Consumer (PNO A) and also informs him about the Id of the new physical link between PNO D and PNO C (the physical link for which PNO B is held responsible). PNO A asks PNO C to cancel the VPSC / VCSC within the PNO subnetwork of PNO C without releasing the Z user and asks PNO C to reserve a new PNO VPSC / VCSC according to the new situation. Due to step three in the scenario the X-interface relation turns from *star* to a mixture of *star* and *cascaded*.

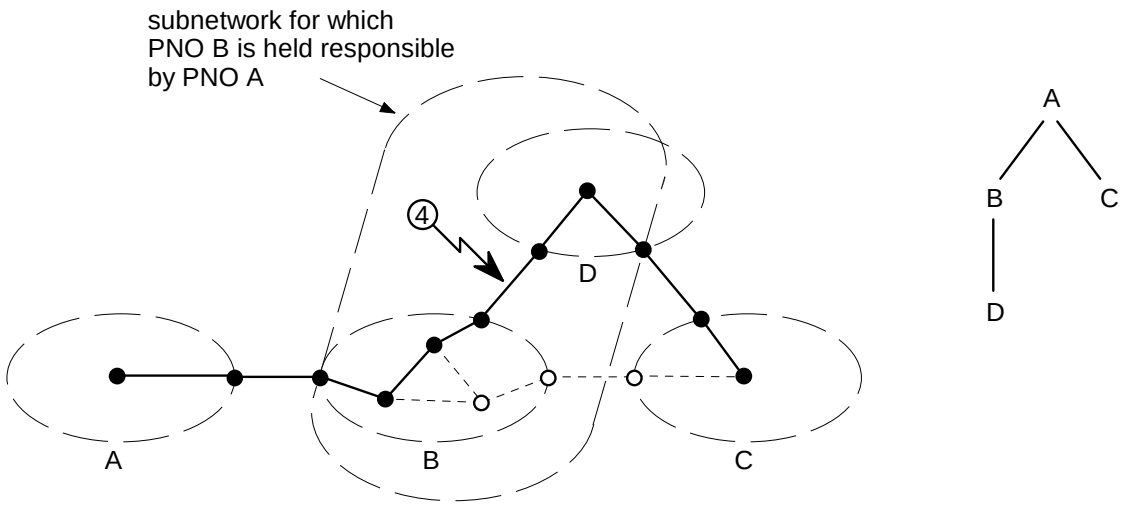

Figure F.5: Step 4 of example scenario

Step 4: A fault has occurred in the physical link between PNO B and PNO D. Because this physical link is now part of the subnetwork of PNO B, PNO B reports the failure to its Consumer (PNO A) as if it were a VPSC / VCSC failure (instead of a link failure). PNO B indicates that the failure is recoverable. PNO B performs protection switching on the inter-PNO VP/VC LC between PNO B and PNO D and notifies its Consumer about this. Associatd alarms should then be suppressed.

F.2 Scenarios

This clause contains scenarios that apply if the cascaded or mixed mode is to be used.

For all scenarios, the following VP/VC connections are possible between PNO A (Initiating) and PNO E (Destination): A-B-C-D-E, A-B-X-Y-D-E and A-B-X-Y-Z-E.

The following cases may be distinguished:

- case 1 (normal): A-B-C-D-E;
- case 2 (resulting from malfunctioning C): A-B-X-Y-D-E;
- case 3 (resulting from malfunctioning D): A-B-X-Y-Z-E.

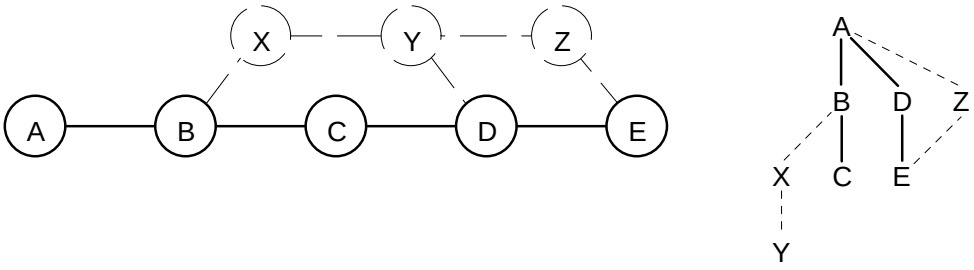
The following X-interface relations apply (of course other X-interface relations may exist, but they are not used in these particular cases; between brackets, the X-interface relations which are no longer used are mentioned):

- case 1: A-B, B-C, A-D and D-E;
- case 2: A-B, (B-C), B-X, X-Y, A-D and D-E;
- case 3: A-B, (B-C), B-X, X-Y, (A-D), (D-E), A-Z, Z-E.

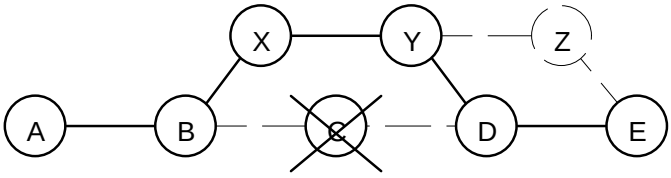
For these cases, the following scenarios are elaborated:

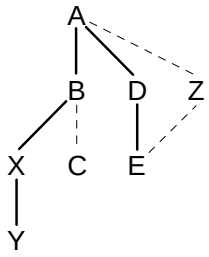
- scenario 1: PNO A establishes a VP/VC connection with PNO E;
- scenario 2: in the end situation of scenario 1, something goes wrong with the connections around PNO C (i.e. going from case 1 to case 2);
- scenario 3: in the end situation of scenario 1, something goes wrong with the connections around PNO D (i.e. going from case 1 to case 3);
- scenario 4: in the end situation of scenario 1, the connection parameters are modified, without changing the route.

Case 1:

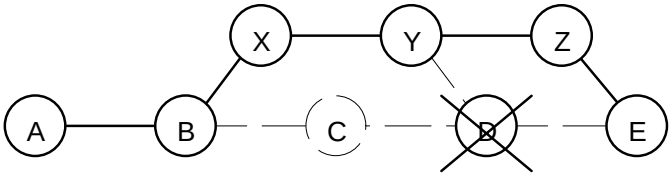


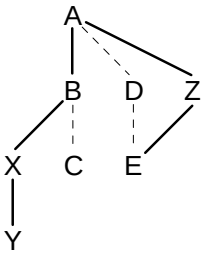
Case 2:



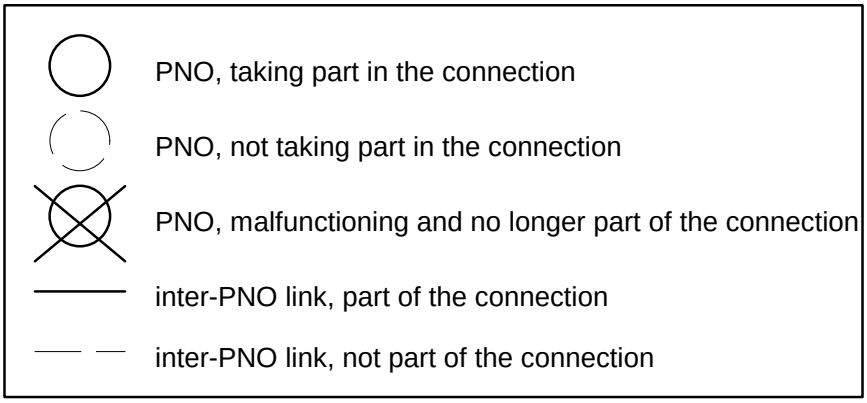


Case 3:

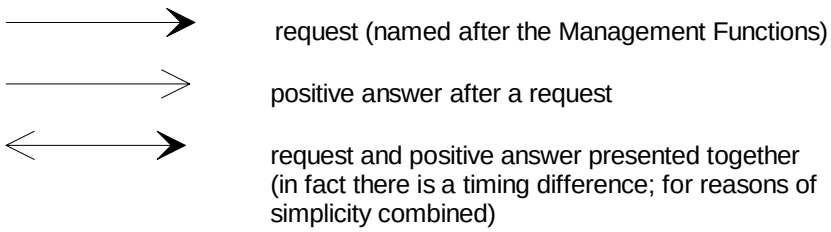




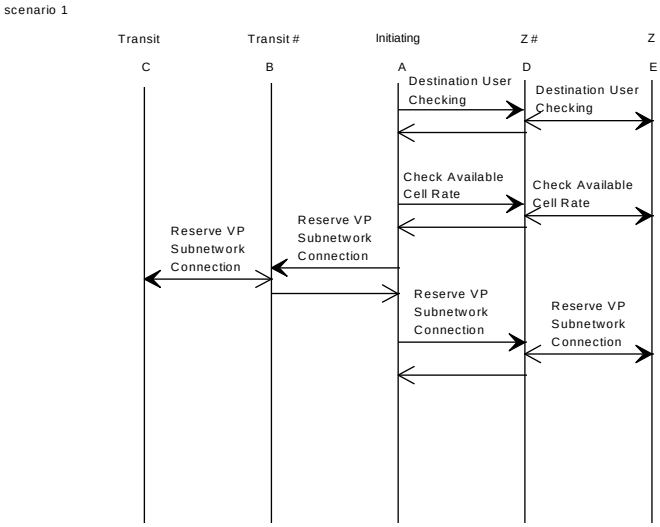
(connection maps) (X-interface relation trees)



In the next figures (flow charts), the following legend is applicable:

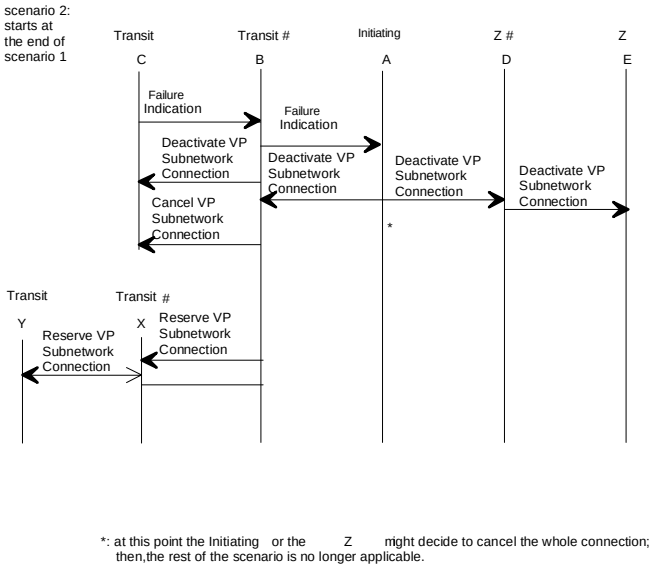


Scenario 1: PNO A establishes a VP/VC connection with PNO E.



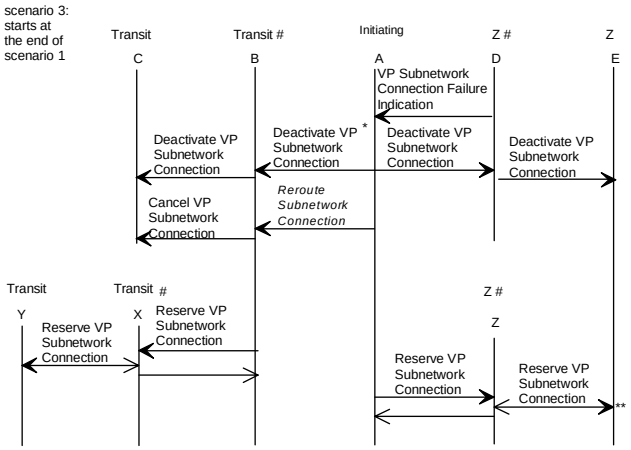
NOTE: Transit # and Z # act respectivly as Transit and Z from the view point of the Initiating PNO, even though they use other Transit and Z PNOs for the establisment of the connection.

Scenario 2: in the end situation of scenario 1, something goes wrong with the connections around PNO C (i.e. going from case 1 to case 2).



NOTE: At this point the Initiating PNO or the Z PNOmight decide to cancel the whole connection, in which case the rest of the scenario is no longer applicable.

Scenario 3: in the end situation of scenario 1, something goes wrong with the connections around PNO D (i.e. going from case 1 to case 3).



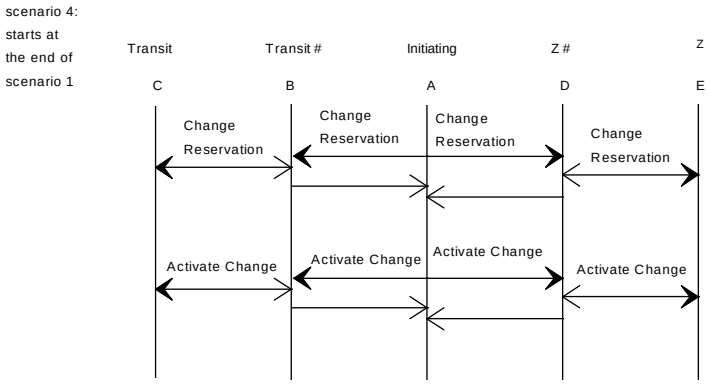
*: at this point the Initiating or the Z might decide to cancel the whole connection; then,the rest of the scenario is no longer applicable.

** since E receives a request for an already allocated VP identifier, E will recognise this as a request to reconnect to the existing connection to its destination user

NOTE 1: At this point the Initiating or the Z PNO might decide to cancel the whole connection, in which case the rest of the scenario is no longer applicable.

NOTE 2: Since PNO E receives a request for an already allocated VP identifier, PNO E will recognize this as a request to reconnect to the existing connection to its destination user.

Scenario 4: in the end situation of scenario 1, the connection parameters are modified, without changing the route.



Annex G (informative): Traffic Descriptor reference problems

Problems in the Abstract Syntax Notation One (ASN.1) part of the present document.

The "Schedule" datatypes (Daily-, Weekly-, Monthly-, Occasional-Schedule) that are in VpSchedulers and defined in the present document are also defined in ES 200 653 [9]. The reason that they are not imported from ES 200 653 [9] is that in ES 200 653 [9] TrafficDescriptor cannot be found.

The situation can be illustrated like this.

Typedefinitions in the old situation: (In the earlier ETSI X-interface versions: EN 300 820-1 [13]).

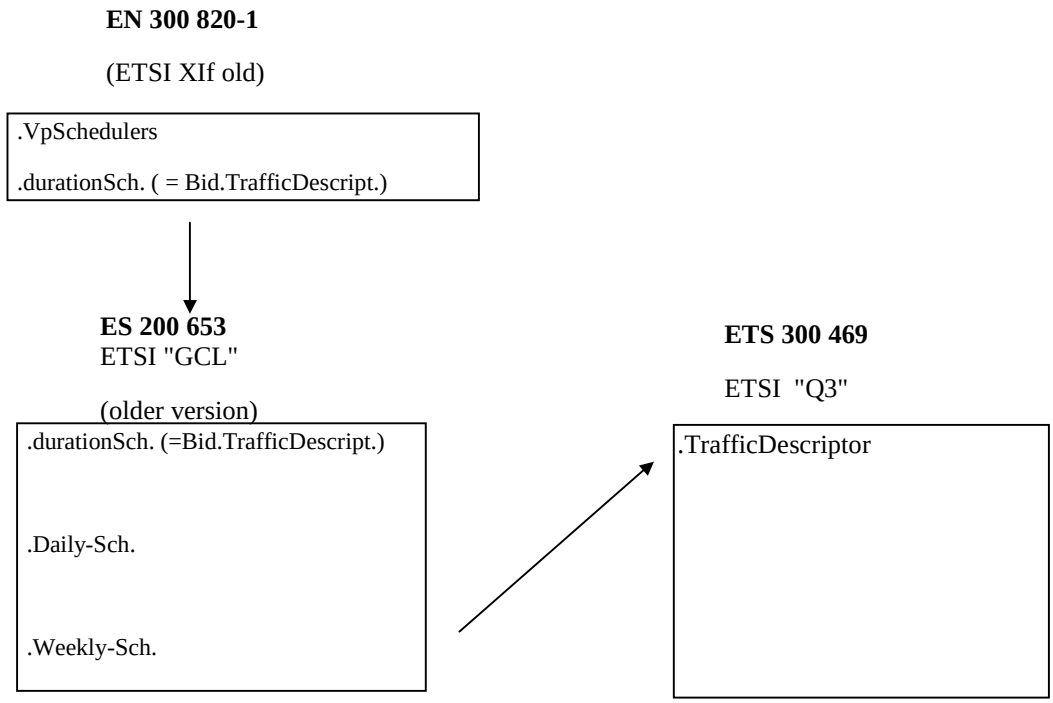


Figure G.1: trafficDescriptor reference during the development of the X-interface

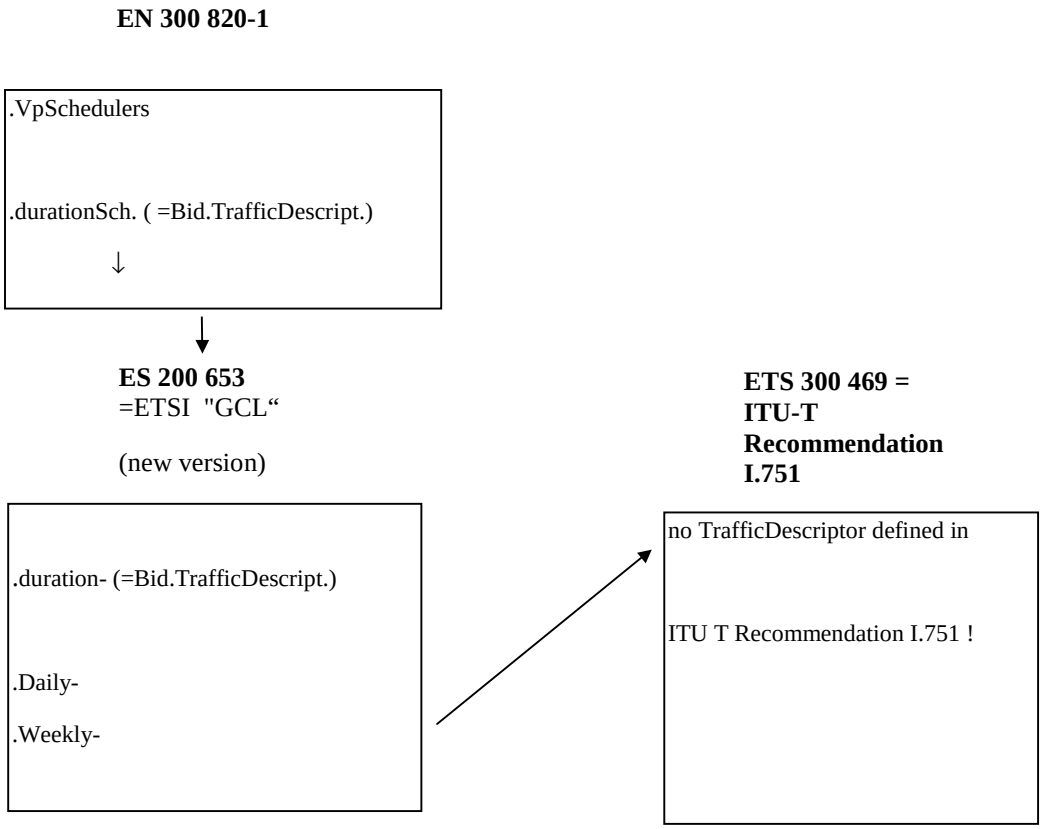

Figure G.2: trafficDescriptor reference problems

The problem is the endorsement of ETS 300 469 [12] with ITU Recommendation I.751 [3]: ETS 300 469 [12] now is a copy of ITU Recommendation I.751 [3]. There is no Type *TrafficDescriptor* defined in ITU Recommendation I.751 [3], so ES 200 653 [9] imports a non-existing Datatype.

To cope with this the Typedefinition *TrafficDescriptor* is included in the present document and all "ScheduleTypes" (and their "subtypes") that are also in ES 200 653 [9] are defined again (copied) in the present document to prevent "circular definitions".

It is recommended that the typedefinition of *TrafficDescriptor* (the one that is defined in the present document) will be included in ES 200 653 [9] in order to be able to remove the typedefinition of the „ScheduleTypes" from the present document.

NOTE: There is a typedefinition *BandwidthScheduling* in ES 200 653 [9] that is the same as *VpSchedulers*, only *monthlySchedule* and *occasionalSchedule* are interchanged.

So later, it is also possible to remove the typedefinition of VpSchedulers from the present document.

Bibliography

The following material, though not specifically referenced in the body of the present document (or not publicly available), gives supporting information.

- ITU-T Recommendation I.610: "B-ISDN operation and maintenance principles and functions".
- ITU-T Recommendation Q.822: "Stage 2 and stage 3 description for the Q3 interface-performance monitoring".
- ITU-T Recommendation Q.821: "Stage 2 and stage 3 description for the Q3 interface-alarm surveillance".
- ITU-T Recommendation X.720: "Information technology - Open Systems Interconnection - Structure of management information: Management information model".
- ITU-T Recommendation X.208: "Specification of Abstract Syntax Notation One".
- ITU-T Recommendation Q.811: "Q3 Lower layers Protocols".
- ITU-T Recommendation Q.812: "Q3 Higher layers Protocols".
- ITU-T Recommendation G.774: "Transmission and multiplexing SDH Information Model for the Network Element view".
- ETSI EN 300 371: "Transmission and Multiplexing (TM); Plesiochronous Digital Hierarchy (PDH) information model for the Network Element (NE) view".
- ITU-T Recommendation M.3020: "TMN Interface Specification Methodology".
- ITU-T Recommendation I.371: "Traffic control and congestion control in B-ISDN".
- ITU-T Recommendation I.357: "B-ISDN semi-permanent connection availability".
