Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "*Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards*", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<https://ipr.etsi.org>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This draft Harmonised European Standard (EN) has been produced by ETSI Technical Committee Broadband Radio Access Networks (BRAN), and is now submitted for the combined Public Enquiry and Vote phase of the ETSI standards EN Approval Procedure.

The present document has been prepared under the Commission's standardisation request C(2015) 5376 final [i.2] to provide one voluntary means of conforming to the essential requirements of Directive 2014/53/EU on the harmonisation of the laws of the Member States relating to the making available on the market of radio equipment and repealing Directive 1999/5/EC [i.6].

Once the present document is cited in the Official Journal of the European Union under that Directive, compliance with the normative clauses of the present document given in table A.1 confers, within the limits of the scope of the present document, a presumption of conformity with the corresponding essential requirements of that Directive, and associated EFTA regulations.

Proposed national transposition dates	
Date of latest announcement of this EN (doa):	3 months after ETSI publication
Date of latest publication of new National Standard or endorsement of this EN (dop/e):	6 months after doa
Date of withdrawal of any conflicting National Standard (dow):	18 months after doa

Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the [ETSI Drafting Rules](#) (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

Introduction

60 GHz radio equipment are capable of operating at data rates of multiple-gigabit per second.

The spectrum usage conditions for this equipment are set in Commission Decision 2006/771/EC [i.5] and ERC Recommendation 70-03 [i.3], annex 3.

1 Scope

The present document specifies technical characteristics and methods of measurements for radio equipment with integral antennas operating at data rates of multiple-gigabit per second in the 60 GHz frequency range.

These radio equipments operate with very wideband communications using a variety of directional medium and high gain antennas to enable a high degree of spectrum reuse, and may use a flexible bandwidth scheme under which they normally operate in a wideband mode, and periodically reduce their bandwidth (e.g. for antenna training and other activities).

The technical characteristics of applications using these radio equipments are further described in ETSI TR 102 555 [i.1].

Equipment in this frequency range intended for outdoor Fixed Local Area Network Extension (FLANE) or Fixed Point-to-Point applications are not in the scope of the present document.

These radio equipment types are capable of operating in all or any part of the frequency bands given in table 1.

Table 1: Radiocommunications service frequency bands

	Radiocommunications service frequency bands
Transmit	57 GHz to 66 GHz
Receive	57 GHz to 66 GHz

The present document covers the essential requirements of article 3.2 of Directive 2014/53/EU [i.6] under the conditions identified in annex A.

2 References

2.1 Normative references

References are specific, identified by date of publication and/or edition number or version number. Only the cited version applies.

Referenced documents which are not found to be publicly available in the expected location might be found at <https://docbox.etsi.org/Reference/>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are necessary for the application of the present document.

Not applicable.

2.2 Informative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are not necessary for the application of the present document but they assist the user with regard to a particular subject area.

[i.1] ETSI TR 102 555: "Electromagnetic compatibility and Radio spectrum Matters (ERM); Technical characteristics of multiple gigabit wireless systems in the 60 GHz range System Reference Document".

- [i.2] Commission Implementing Decision C(2015) 5376 final of 4.8.2015 on a standardisation request to the European Committee for Electrotechnical Standardisation and to the European Telecommunications Standards Institute as regards radio equipment in support of Directive 2014/53/EU of the European Parliament and of the Council.
- [i.3] ERC Recommendation 70-03 (Tromsø 1997 and subsequent amendments): "Related to the Use of Short Range Devices (SRD)".
- [i.4] Void.
- [i.5] Commission Decision 2006/771/EC of 9 November 2006 on harmonisation of the radio spectrum for use by short-range devices.
- [i.6] Directive 2014/53/EU of the European Parliament and of the Council of 16 April 2014 on the harmonisation of the laws of the Member States relating to the making available on the market of radio equipment and repealing Directive 1999/5/EC.
- [i.7] ETSI TR 100 028-2 (V1.4.1): "Electromagnetic compatibility and Radio spectrum Matters (ERM); Uncertainties in the measurement of mobile radio equipment characteristics; Part 2".

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in Directive 2014/53/EU [i.6] and the following apply:

60 GHz range or 60 GHz band: one of the variously permitted frequencies of operation, typically from 57 GHz to 66 GHz

activity factor: percentage over any one minute time period when equipment is operating under a given set of conditions

adjacent channel: channels on either side of the nominal channel separated by the nominal channel bandwidth

channel separation: minimum separation (in MHz) between the centre frequencies of two adjacent channels in the channel plan of the radio equipment

integral antenna: antenna which is declared to be part of the radio equipment by the manufacturer

NOTE 1: In some cases, it may not be possible to remove an integral antenna or expose an antenna connector without changing the output characteristics of the radio equipment.

NOTE 2: Even with an integral antenna, it might still be possible to separate the antenna from the equipment using a special tool.

mean power: average power (transmitted or received) during an interval of time sufficiently long to capture the On Time of the signal

nominal channel bandwidth: band of frequencies assigned to a single channel

NOTE: The Nominal Channel Bandwidth is declared by the manufacturer as outlined in clause 5.3.1.

occupied bandwidth: frequency bandwidth of the signal including 99 % of the energy below the lower and above the upper frequency limits, the mean power emitted is equal to 0,5 % of the total mean power of the emission

smart antenna systems: equipment that combines multiple transmit and/or receive antenna elements with a signal processing function to increase its radiation and/or reception capabilities

NOTE: This includes techniques such as spatial multiplexing, beam forming, cyclic delay diversity, etc.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

dBc	spectral density relative to the maximum spectral power density of the transmitted signal
dBm	decibel relative to one milliwatt
dBr	decibel relative to a given maximum power level
GHz	thousand millions of cycles
kHz	thousands of cycles
µs	millionths of seconds

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

BW	BandWidth
CCA	Clear Channel Assessment
CW	Continuous Wave
EIRP	Equivalent Isotropically Radiated Power
ERP	Effective Radiated Power
FER	Frame Error Rate
FLANE	Fixed Local Area Network Extension
LBT	Listen Before Talk
MCS	Modulation and Coding Scheme
PD	Power Density
PDL	spectral Power Density Limit
RBW	Resolution BandWidth
RF	Radio Frequency
RLAN	Radio Local Area Network
RMS	Root Mean Square
UUT	Unit Under Test
VBW	Video BandWidth

4 Technical requirements specifications

4.1 Environmental profile

The technical requirements of the present document apply under the environmental profile for operation of the equipment, which shall be declared by the manufacturer. The equipment shall comply with all the technical requirements of the present document which are identified as applicable in annex A at all times when operating within the boundary limits of the declared operational environmental profile.

4.2 Conformance requirements

4.2.1 Spectral power density

4.2.1.1 Definition

The spectral power density is the mean Equivalent Isotropically Radiated Power (EIRP) density in dBm per Megahertz during a transmission burst.

4.2.1.2 Limit

The maximum spectral power density is applicable to the system as a whole when operated at the highest power spectral density level (EIRP). The maximum spectral power density shall be as indicated in table 2.

Table 2: Spectral power density limit (PDL)

Usage	Maximum spectral power density (EIRP)
Indoor and Outdoor	13 dBm / MHz

4.2.1.3 Conformance

Conformance tests as defined in clause 5.3.3 shall be carried out.

4.2.2 RF output power

4.2.2.1 Definition

The RF output power is the mean equivalent isotropically radiated power (EIRP) for the equipment during a transmission burst.

4.2.2.2 Limit

The maximum RF output power is applicable to the system as a whole when operated at the highest stated power level. For a smart antenna system, the limit applies to the configuration that results in the highest EIRP. In case of multiple (adjacent or non-adjacent) channels the total RF output power of all channels shall be less than or equal to the limits in table 3.

The maximum RF output power shall be as indicated in table 3.

Table 3: RF output power limit

Usage	Maximum power level (EIRP)
Indoor and Outdoor	40 dBm

4.2.2.3 Conformance

Conformance tests as defined in clause 5.3.4 shall be carried out.

4.2.3 Transmitter unwanted emissions

4.2.3.1 Definition

Transmitter unwanted emissions are unwanted emissions in the spurious domain while the equipment is transmitting. The boundary where the spurious domain begins is considered to be the offset from the nominal centre frequency of the transmission by $\pm 250\%$ of the nominal channel BW for nominal channel BW ≤ 500 MHz and $\pm (500 \text{ MHz} + 1,5 \times \text{nominal channel BW})$ for nominal channel BW > 500 MHz.

4.2.3.2 Limit

The level of unwanted emissions in the spurious domain shall be less than or equal to the limits given in table 4.

Table 4: Transmitter spurious emissions

Frequency range	Emission Limit ERP (\leq 1 GHz) EIRP ($>$ 1 GHz)	Measurement Bandwidth
30 MHz to 47 MHz	-36 dBm	100 kHz
47 MHz to 74 MHz	-54 dBm	100 kHz
74 MHz to 87,5 MHz	-36 dBm	100 kHz
87,5 MHz to 118 MHz	-54 dBm	100 kHz
118 MHz to 174 MHz	-36 dBm	100 kHz
174 MHz to 230 MHz	-54 dBm	100 kHz
230 MHz to 470 MHz	-36 dBm	100 kHz
470 MHz to 790 MHz	-54 dBm	100 kHz
790 MHz to 1 GHz	-36 dBm	100 kHz
1 GHz to 132 GHz	-30 dBm	1 MHz

4.2.3.3 Conformance

Conformance tests as defined in clause 5.3.5 shall be carried out.

4.2.4 Receiver unwanted emissions

4.2.4.1 Definition

These are unwanted emissions in the spurious domain while the equipment is receiving a transmission.

4.2.4.2 Limit

The level of unwanted emissions in the spurious domain shall be less than or equal to the limits given in table 5.

Table 5: Receiver spurious emissions

Frequency band	Emission Limit ERP (\leq 1 GHz) EIRP ($>$ 1 GHz)	Measurement Bandwidth
30 MHz to 1 GHz	-57 dBm	100 kHz
1 GHz to 132 GHz	-47 dBm	1 MHz

4.2.4.3 Conformance

Conformance tests as defined in clause 5.3.6 shall be carried out.

4.2.5 Adaptivity (medium access protocol)

4.2.5.1 Applicability

The present requirement applies to all equipment within the scope of the present document.

4.2.5.2 Definition

Adaptivity (medium access protocol) is a mechanism designed to facilitate spectrum sharing with other devices in the wireless network.

4.2.5.3 Requirement

Adaptivity (medium access protocol) shall be implemented by the equipment and shall be active under all circumstances.

LBT is mandatory to facilitate spectrum sharing.

The LBT mechanism is as follows:

- 1) Before a transmission or a burst of transmissions on an Operating Channel, the equipment shall perform a Clear Channel Assessment (CCA) check using "energy detect". The equipment shall observe the Operating Channel(s) for the duration of the CCA observation time measured by multiple CCA slot times of 5 μ s. The Operating Channel shall be considered occupied for a slot time if the energy level in the channel exceeds the threshold corresponding to the power level given in step 5) below.
- 2) Extended CCA Check definition:
 - a) An extended CCA check is initiated at end of operating channel occupied.
 - b) The transmission shall not start earlier than 8 μ s while observing CCA empty.
 - c) The transmission deferring continues for a random number of empty slots period.
 - d) Random number: ranges from zero to a Max number not greater than 127.
 - e) Extended CCA Check Time equals b) + c), i.e. 8 μ s + random(0 to 127) \times 5 μ s.
- 3) The equipment shall perform an *Extended CCA Check* in the *Operating Channel*. If the equipment finds an *Operating Channel* occupied, it shall not transmit in that channel. If the extended CCA check has determined the channel to be no longer occupied for the entire Extended CCA Check Time, the equipment may resume transmissions on this channel.
- 4) The total time that an equipment makes use of an *Operating Channel* is defined as the **Channel Occupancy Time**. This Channel Occupancy Time shall be less than 9 ms, after which the device shall perform a new CCA as described in step 1) and step 2) above.
- 5) The equipment, upon correct reception of a packet which was intended for this equipment, can skip CCA and immediately proceed with the transmission in response to received frames. A consecutive sequence of transmissions by the equipment, without a new CCA, shall be less than or equal to the **Maximum Channel Occupancy Time** as defined in step 3) above.
- 6) The energy detection threshold for the CCA shall be $-47 \text{ dBm} + (40 \text{ dBm} - P_{\text{out}} (\text{dBm}))$ assuming 0 dBi antenna gain.

4.2.5.4 Conformance

The conformance tests as defined in clause 5.3.8 shall be carried out.

4.2.6 Void

4.2.7 Receiver Adjacent Channel Rejection

4.2.7.1 Applicability

The present requirement applies to all equipment within the scope of the present document.

4.2.7.2 Definition

The receiver adjacent channel rejection is a measure of the receiver's ability to receive a wanted signal at its assigned channel frequency in the presence of an unwanted signal at a given frequency offset from the centre frequency of the assigned channel, without this unwanted signal causing a degradation of the performance of the receiver beyond minimum performance criteria as specified in clause 4.2.7.3.

4.2.7.3 Performance Criteria

The equipment shall meet the minimum performance level as declared by the manufacturer for the intended use of the equipment, see clause 5.3.1. The declaration of the minimum performance level may be replaced by declaring a permissible degradation of performance.

4.2.7.4 Limits

While maintaining the minimum performance criteria as defined in clause 4.2.7.3 the levels at the unwanted signal frequencies shall be equal to or greater than the limits defined in table 6.

Table 6: Receiver Adjacent Channel Rejection level

Wanted signal mean power from companion device (dBm) at the input of UUT	Unwanted signal frequency (GHz)	Unwanted signal power (dBm) at the input of UUT assuming 0 dBi antenna gain	Type of unwanted signal
P _{min} + 6 dB	Operating Channel Centre Frequency - Nominal Channel BW	-65	CW
P _{min} + 6 dB	Operating Channel Centre Frequency + Nominal Channel BW	-65	CW
NOTE 1: P _{min} is the minimum level of the wanted signal required to meet the minimum performance criteria in the absence of any interference signal.			
NOTE 2: For equipment with antenna gain different than 0 dBi, the antenna gain shall be subtracted from the unwanted signal power.			

4.2.7.5 Conformance

The conformance tests as defined in clause 5.3.7 shall be carried out.

4.2.8 Transmitter unwanted emissions in the out-of-band domain

4.2.8.1 Definition

Transmitter unwanted emissions in the out-of-band domain are emissions when the equipment is in transmit mode, on frequencies immediately outside the necessary bandwidth which results from the modulation process, but excluding spurious emissions.

4.2.8.2 Limit

The transmitter unwanted emissions in the out-of-band domain shall be less than or equal to the relative limits provided in figure 1 where BW represents the declared nominal channel BW or an absolute level of -30 dBm with a 1 MHz measurement bandwidth, whichever is the greater. Non-adjacent channels shall be tested separately.

Figure 1: Transmit Mask

4.2.8.3 Conformance

Conformance tests as defined in clause 5.3.9 shall be carried out.

4.2.9 Geo-location capability

4.2.9.1 Applicability

This requirement only applies to equipment with geo-location capability as defined in clause 4.2.9.2.

4.2.9.2 Definition

Geo-location capability is a feature of the equipment to determine its geographical location with the purpose to configure itself according to the regulatory requirements applicable at the geographical location where it operates.

The geo-location capability may be present in the equipment or in an external device (temporary) associated with the equipment operating at the same geographical location during the initial power up of the equipment. The geographical location may also be available in equipment already installed and operating at the same geographical location.

4.2.9.3 Requirements

The geographical location determined by the equipment as defined in clause 4.2.9.2 shall not be accessible to the user.

If the equipment cannot determine the geographical location, it shall operate in a mode compliant with the requirements applicable in any of the geographical locations where the equipment is intended to operate.

4.2.9.4 Conformance

The manufacturer shall declare whether the equipment complies with the requirements contained in clause 4.2.9.3. See clause 5.3.1.

4.2.10 Occupied Channel Bandwidth

4.2.10.1 Applicability

This requirement applies to all equipment within the scope of the present document.

4.2.10.2 Definition

The Nominal Channel Bandwidth is the widest band of frequencies, inclusive of guard bands, assigned to a single channel.

The Occupied Channel Bandwidth is the bandwidth containing 99 % of the power of the signal.

When equipment has simultaneous transmissions in adjacent channels, these transmissions may be considered as one signal with an actual Nominal Channel Bandwidth of "n" times the individual Nominal Channel Bandwidth where "n" is the number of adjacent channels. When equipment has simultaneous transmissions in non-adjacent channels, each power envelope shall be considered separately.

4.2.10.3 Requirements

The Occupied Channel Bandwidth shall be between 70 % and 100 % of the declared Nominal Channel Bandwidth. In case of smart antenna systems (devices with multiple transmit chains) each of the transmit chains shall meet this requirement.

4.2.10.4 Conformance

Conformance tests as defined in clause 5.3.10 shall be carried out.

5 Testing for compliance with technical requirements

5.1 Environmental conditions for testing

5.1.1 Introduction

Tests defined in the present document shall be carried out at representative points within the boundary limits of the declared operational environmental profile.

Where technical performance varies subject to environmental conditions, tests shall be carried out under a sufficient variety of environmental conditions (within the boundary limits of the declared operational environmental profile) to give confidence of compliance for the affected technical requirements.

For each test defined in the present document, the environmental condition(s) at which the test has to be performed is specified in the clause on test conditions for that particular test.

5.1.2 Normal test conditions

5.1.2.1 Normal temperature and humidity

The normal temperature and humidity conditions for tests shall be any convenient combination of temperature and humidity within the following ranges:

- temperature: +15 °C to +35 °C;
- relative humidity: 20 % to 75 %.

The actual values during the tests shall be recorded.

5.1.2.2 Normal power source

The normal test voltage for the equipment shall be the nominal voltage for which the equipment was designed.

5.2 Interpretation of the measurement results

The interpretation of the results recorded in a test report for the measurements described in the present document shall be as follows:

- the measured value related to the corresponding limit will be used to decide whether an equipment meets the requirements of the present document;
- the value of the measurement uncertainty for the measurement of each parameter shall be included in the test report;
- the recorded value of the measurement uncertainty shall be, for each measurement, equal to or less than the figures in table 7.

For the test methods, according to the present document, the measurement uncertainty figures shall be calculated and shall correspond to an expansion factor (coverage factor) $k = 1,96$ or $k = 2$ (which provide confidence levels of respectively 95 % and 95,45 % in the case where the distributions characterizing the actual measurement uncertainties are normal (Gaussian)). Principles for the calculation of measurement uncertainty are contained in annex D of the ETSI TR 100 028-2 [i.7].

Table 7 is based on such expansion factors.

Table 7: Maximum measurement uncertainty

Parameter	Uncertainty
Radio Frequency	±10 ppm
RF power, radiated	±6 dB
Spurious emissions, radiated	±6 dB
Humidity	±5 %
Temperature	±2 °C
Time	±10 %

5.3 Test procedure for the essential radio test suites

5.3.1 Product Information

The information requested in the present clause shall be declared by the manufacturer and shall be included in the test report. This information is required in order to carry out the test suites and/or to declare compliance to technical requirements (e.g. technical requirements for which no conformance test is included in the present document):

- The channel plan(s), being the centre frequencies that the UUT is capable of tuning. If the equipment is capable of supporting multiple channel plans in the course of normal operation (e.g. offering different sizes of normal wideband operation), each distinct channel plan and its related nominal channel bandwidth for normal wideband operation shall be stated.
- The test modulation(s) used by the UUT.
- Gain of the integral antenna including beamforming gain if supported.
- Minimum performance criteria as defined in clause 4.2.7 that corresponds to the intended use of the equipment.
- Geo-Location Capability.

5.3.2 Test modulation, frequency and configuration

The test modulation used should be representative of normal use of the equipment. Where the equipment is not capable of continuous RF transmission, the test modulation shall be such that:

- a) The generated RF transmission is the same for each transmission.
- b) Transmissions occur regularly in time.
- c) Sequences of transmissions can be repeated accurately.

If the equipment uses multiple modulation methods with different RF characteristics, the modulation that produces the worst values for each essential radio test shall be used and this modulation shall be stated along with the rationale for why this modulation produces worse values than other modulation methods used by the equipment.

All tests shall be conducted at the following channels within the stated channel plan(s):

- a) The channel with the lowest operating frequency.
- b) The channel with the highest operating frequency.
- c) The channel with the frequency closest to the midpoint of the stated operating frequency range.

If the UUT is capable of supporting multiple nominal channel bandwidths for wideband normal operations, tests shall be conducted for each one of them.

When applicable, RF output power shall also be tested during narrowband activity operation.

The Channel Separation (ChS) value shall be calculated based on the minimum separation (in MHz) between any two centre channel frequencies in the channel plan.

In the case that the RF power level is adjustable, all measurements shall be made with the highest power level available.

In the case of smart antenna systems, the UUT should be configured to deliver the highest RF output power to the measurement equipment, and the method to do this shall be documented in the test report.

Radiated measurements shall be used in all cases given the use of integral antennas and the lack of suitable methods for conducted measurements for this type of equipment.

5.3.3 Spectral power density

The maximum spectral power density, subject to the conditions outlined in clause 5.1, clause 5.2 and clause 5.3.2 shall be measured using a test site as described in annex C and applicable measurement procedures in annex D shall be measured and recorded for conformance with the requirements in clause 4.2.1.

The maximum spectral power density shall be determined using a spectrum analyser of adequate bandwidth for the type of modulation being used in combination with a RF power meter.

For the purpose of this test, the minimum transmitter on time shall be 10 μ s. For equipment where the transmitter on time is less than 10 μ s, the method of measurement shall be documented in the test report.

The test procedure shall be as follows:

Step 1:

The spectrum analyser shall use the following settings:

- a) Centre frequency: The centre frequency of the channel under test.
- b) Resolution bandwidth: 1 MHz.
- c) Video bandwidth: 1 MHz.
- d) Frequency span: $2 \times$ Nominal channel bandwidth.
- e) Detector: Peak.

- f) Trace mode: Max hold.

Step 2:

When the trace is complete, find the peak value of the power envelope and record the frequency.

Step 3:

Make the following changes to the settings of the spectrum analyser:

- a) Centre frequency: Equal to the frequency recorded in step 2.
- b) Resolution bandwidth: 1 MHz.
- c) Video bandwidth: 1 MHz.
- d) Frequency span: 3 MHz.
- e) Sweep time: 1 minute.
- f) Detector: RMS Average, Sample, or Average (excepting Video Average).
- g) Trace mode: Max hold.

For devices with a Nominal Channel bandwidth greater than 100 MHz, a resolution bandwidth (RBW) other than 1 MHz as specified in step 3 may be used. This resolution bandwidth shall not be less than 1 MHz nor greater than 100 MHz. If a resolution bandwidth other than 1 MHz is employed, the power density limit that will be used in step 4 shall be $PDL(RBW) = PDL(1 \text{ MHz}) + 10 \times \log_{10}(RBW)$ where RBW is the resolution bandwidth in MHz that is employed, $PDL(1 \text{ MHz})$ is the power density limit at 1 MHz resolution bandwidth, and $PDL(RBW)$ is the power density limit at the resolution bandwidth used. The video bandwidth shall be the same as the resolution bandwidth, and the frequency span shall be three times this substitute resolution bandwidth.

Step 4:

When the trace is complete, capture the trace, for example, using the "View" option on the spectrum analyser.

Find the peak value of the trace and place the analyser marker on this peak. This level is recorded as the highest spectral power density D in a 1 MHz band (or other substitute resolution as noted above).

Alternatively, where a spectrum analyser is equipment with a facility to measure spectral power density, this facility may be used to display the spectral power density D in dBm/1 MHz (or other substitute resolution as noted above).

The maximum EIRP spectral density is calculated from the above measured power density (D) and the observed duty cycle x , according to the formula below and shall be recorded in the test report. Note that PD is specified for a 1 MHz bandwidth unless a substitute resolution is used as noted above.

$$PD = D + 10 \times \log_{10}(1 / x).$$

Where the spectrum analyser bandwidth is non-Gaussian, a suitable correction factor shall be determined and applied.

5.3.4 RF output power

The RF output power, subject to the conditions outlined in clause 5.1, clause 5.2 and clause 5.3.2, shall be measured using a test site as described in annex C and applicable measurement procedures in annex D shall be measured and recorded for conformance with the requirements in clause 4.2.2.

The centre frequency of all equipment shall be verified as being in the 60 GHz band.

Step 1:

- a) Using suitable attenuators, the measurement equipment shall be coupled to a matched diode detector or equivalent thereof. The output of the diode detector shall be connected to the vertical channel of an oscilloscope or equivalent power measurement equipment.
- b) The combination of the diode detector and the oscilloscope shall be capable of faithfully reproducing the duty cycle of the transmitter output signal.

- c) The observed duty cycle of the transmitter (Tx on / (Tx on + Tx off)) shall be noted as x ($0 < x \leq 1$), and recorded in the test report. For the purpose of testing, the equipment shall be operated with a duty cycle that is equal to or greater than 0,1.

Step 2:

- d) The RF output power of the transmitter when operated at the highest power level shall be measured using a spectrum analyser with an integration factor that exceeds the repetition period of the transmitter by a factor of 5 or more. The observed value shall be noted as "A" (in dBm).
- e) The EIRP shall be calculated from the above measured power output A (in dBm) and the observed duty cycle x according to the formula below shall be recorded.
- f) $P = A + 10 \times \log_{10} (1 / x)$.

5.3.5 Transmitter unwanted emissions

5.3.5.0 Introduction

The transmitter unwanted emissions, subject to the conditions outlined in clause 5.1, clause 5.2 and clause 5.3.2, shall be measured using a test site as described in annex C and applicable measurement procedures in annex D, shall be measured and recorded for conformance with the requirements in clause 4.2.3.

In case of radiated measurements on antenna array systems using symmetrical power distribution across the available transmit chains, the UUT should, where possible, be configured so that only one transmit chain (antenna) is activated while the other transmit chains are disabled. Where this is not possible, the method used shall be documented in the test report.

If only one transmit chain was tested, the result for the active transmit chain shall be corrected to be valid for the whole system (all transmit chains).

The emission power (mW) for one transmit chain needs to be multiplied with the number of transmit chains to obtain the total emission power of the system.

For the purposes of these tests, the UUT shall be configured to operate at its maximum duty cycle and maximum RF output power level.

5.3.5.1 Pre-scan

The test procedure below shall be used to identify potential unwanted emissions of the UUT.

Step 1:

The sensitivity of the spectrum analyser should be such that the noise floor is at least 6 dB below the limits given in table 4.

Step 2:

The emissions shall be measured over the range 30 MHz to 1 GHz:

- | | | |
|----|-----------------------|--|
| a) | Resolution bandwidth: | 100 kHz. |
| b) | Video bandwidth: | 100 kHz. |
| c) | Detector mode: | Average. |
| d) | Trace mode: | Max hold. |
| e) | Sweep time: | For non-continuous transmissions, the sweep time shall be sufficiently long, such that for each 100 kHz frequency step, the measurement time is greater than two transmissions of the UUT. |

The emissions shall be measured over the range 1 GHz to 132 GHz:

- f) Resolution bandwidth: 1 MHz.
- g) Video bandwidth: 1 MHz.
- h) Detector mode: Average.
- i) Trace mode: Max hold.
- j) Sweep time: For non-continuous transmissions, the sweep time shall be sufficiently long, such that for each 1 MHz frequency step, the measurement time is greater than two transmissions of the UUT.

Any emissions identified during the sweeps above that fall within the 6 dB range below the applicable limit shall be individually measured using the procedure in clause 5.3.5.2 and compared to the limits given in table 4. If measurements are conducted at a different distance than specified, then calculations for the equivalent field strength values shall be shown.

5.3.5.2 Identified emissions

Unwanted emissions within the lower spurious domain or the upper spurious domain that are identified during the pre-scan measurements above shall be accurately measured per the procedure below.

The lower spurious domain is defined as the range from the minimum frequency measured to either the nominal centre frequency - 250 % of the Nominal Channel BW for Nominal Channel BW \leq 500 MHz or the nominal centre frequency - (500 MHz + 1,5 \times Nominal Channel BW) for Nominal Channel BW > 500 MHz.

The upper spurious domain is defined as the range from either the nominal centre frequency + 250 % of the Nominal Channel BW for Nominal Channel BW \leq 500 MHz or the nominal centre frequency + (500 MHz + 1,5 \times Nominal Channel BW) for Nominal Channel BW > 500 MHz to the maximum frequency measured.

Step 1 and step 2 below shall be used to accurately measure the individual unwanted emissions identified during the pre-scan measurements above.

For continuous transmit signals, a measurement using the Video Average detector of the spectrum analyser is permitted. Otherwise, the measurement shall be made only over the "on" part of the transmission.

Step 1:

The level of the emissions shall be measured in the time domain, using the following spectrum analyser settings:

- a) Centre frequency: Frequency of emission identified during the pre-scan.
- b) Resolution bandwidth: 100 kHz if < 1 GHz; 1 MHz if > 1 GHz.
- c) Video bandwidth: 100 kHz if < 1 GHz; 1 MHz if > 1 GHz.
- d) Frequency span: 0 Hz.
- e) Sweep time: Suitable to capture one transmission burst.
- f) Trigger: Video trigger.
- g) Detector: Average.
- h) Trace mode: Clear write.

The centre frequency (fine tune) shall be adjusted to capture the highest level of one burst of the emission to be measured.

Step 2:

Change the following setting on the spectrum analyser:

- i) Detector: Video average, minimum of 100 sweeps.

The measured value is the average power of this emission during the on-time of the burst. The value shall be recorded and compared with the limit in table 4.

5.3.6 Receiver unwanted emissions

5.3.6.0 Introduction

The receiver unwanted emissions, subject to the conditions outlined in clause 5.1, clause 5.2 and clause 5.3.2, shall be measured using a test site as described in annex C and applicable measurement procedures in annex D, shall be measured and recorded for conformance with the requirements in clause 4.2.4.

In case of radiated measurements on antenna array systems using identical receive chains, the UUT should, where possible, be configured so that only one receive chain (antenna) is activated while the other receive chains are disabled. Where this is not possible, the method used shall be documented in the test report.

If only one receive chain was tested, the result for the active receive chain shall be corrected to be valid for the whole system (all receive chains).

The emission power for one receive chain needs to be multiplied with the number of receive chains to obtain the total emission power of the system.

The UUT shall be configured to a continuous receive mode or operated in a mode where no transmission occur.

5.3.6.1 Pre-scan

The test procedure below shall be used to identify potential unwanted emissions of the UUT.

Step 1:

The sensitivity of the spectrum analyser should be such that the noise floor is at least 6 dB below the limits given in table 5.

Step 2:

The emissions shall be measured over the range 30 MHz to 1 GHz:

- a) Resolution bandwidth: 100 kHz.
- b) Video bandwidth: 100 kHz.
- c) Detector mode: Average.
- d) Trace mode: Max hold.

The emissions shall be measured over the range 1 GHz to 132 GHz:

- e) Resolution bandwidth: 1 MHz.
- f) Video bandwidth: 1 MHz.
- g) Detector mode: Average.
- h) Trace mode: Max hold.

Any emissions identified during the sweeps above that fall within the 6 dB range below the applicable limit shall be individually measured using the procedure in clause 5.3.6.2 and compared to the limits given in table 5.

5.3.6.2 Identified emissions

Unwanted emissions that are identified during the pre-scan measurements above shall be accurately measured per the procedure below.

The measured values shall be recorded and compared with the limits in table 5. If measurements are conducted at a different distance than specified, then calculations for the equivalent field strength values shall be shown.

The following spectrum analyser settings shall be used:

- a) Centre frequency: Frequency of emission identified during the pre-scan.
- b) Resolution bandwidth: 100 kHz if < 1 GHz; 1 MHz if > 1 GHz.
- c) Video bandwidth: 100 kHz if < 1 GHz; 1 MHz if > 1 GHz.
- d) Detector mode: Average.
- e) Trace mode: Max hold.

5.3.7 Receiver Adjacent Channel Rejection

5.3.7.1 Test conditions

See clause 5.1 for the test conditions. These measurements shall only be performed at normal test conditions.

This test shall be performed on all operating carrier frequencies (channels) used by the equipment.

If the equipment can operate with different Nominal Channel Bandwidths, then the smallest channel bandwidth shall be used. The equipment shall be configured in a mode that results in the lowest data rate for this channel bandwidth.

The type of interference used for testing is continuous wave.

5.3.7.2 Test Method

Figure 2 describes the test set-up. Both the UUT and the Companion Device shall be provided by the manufacturer. The manufacturer shall provide a method for generating transmission from the Companion Device and measuring the Frame Error Rate (FER) at the UUT, while controlling the channel selection, the data rate (MCS), and setting the Beamforming appropriately.

Figure 2: Test Set-up for verifying the Adjacent Channel Rejection of an equipment

The Receive Power of the CW Blocking Signal should be calibrated, e.g. by replacing the UUT with a standard reference antenna connected to a Power Meter.

Step 1 to step 4 below define the procedure to verify the Adjacent Channel Rejection requirement as described in clause 4.2.7.

Step 1:

- The Signal Source, the UUT and the Companion Device are connected using the set-up given by figure 2 although the Signal Source is switched off at this moment.

- Adjust the level of the wanted signal, by controlling the 60 GHz attenuator to the lowest possible level at which the performance criteria as specified in clause 4.2.7.3 is met. Alternatively, it is possible to reduce Tx Power of companion device.
- The level of the wanted signal measured at the UUT input is the Receiver Sensitivity (P_{min}) for the UUT.

Step 2:

- Adjust the received (wanted) signal level at the UUT to be 6 dB above the level P_{min} , by reducing the attenuation by 6 dB.
- Configure the Signal Source for the first frequency in table 6.

Step 3:

- It shall be verified and recorded in the test report that the performance criteria as specified in clause 4.2.7.3 is met.

Step 4:

- Repeat step 3 for each of the signals (frequency and power) contained in table 6 and for each channel used by the equipment.

5.3.8 Adaptivity (medium access protocol)

5.3.8.1 Test conditions

These measurements shall only be performed at normal test conditions.

The device shall be configured to operate at its maximum output power level.

Radiated measurement shall be performed in an anechoic chamber or open air test site, see annex C.

5.3.8.2 Test method

The principle is to establish a communication between UUT and companion device, and then check the behaviour of UUT in the presence of an interferer.

The UUT may be connected to a companion device during the test. When performing this test of a UUT with directional antenna (such as array antenna system capable of beam-forming), the wanted communication link (between the UUT and the companion device) and the interference signal shall be aligned to the direction corresponding to the UUT's maximum EIRP.

Step 1 to step 5 below define the procedure to verify the efficiency of the mechanism supported by equipment.

Step 1:

- The UUT may connect to a companion device during the test. The set-up for radiated testing will include signal generator able to simulate an interferer, spectrum analyser or oscilloscope with two channels, with each channel connected to separate directed antenna, one directed to UUT and the other to the companion device, UUT and the companion device to connect with, but the signal generator does not yet generate any signals at this point in time. The spectrum analyser or oscilloscope is used to monitor the transmissions of the UUT in response to the interference signal.
- When performing testing on a UUT with a directional antenna system (such as array capable of beam-forming), the wanted communication link (between UUT and companion device) and the interference test signals shall be aligned to the direction corresponding to the UUT's maximum EIRP.
- The received signal level (wanted signal from the companion device) at the UUT shall be sufficient to maintain a reliable link for the duration of the test.

- The analyser shall be set as follows:
 - RBW: \geq Nominal Channel Bandwidth (if the analyser does not support this setting, then 8 MHz minimum shall be used)
 - VBW: $3 \times$ RBW (if the analyser does not support this setting, the highest available setting shall be used)
 - Detector Mode: RMS
 - Centre Frequency: Equal to the centre frequency of the operating channel
 - Span: 0 Hz
 - Sweep time: $>$ Channel Occupancy Time / 100 ms
 - Trace Mode: Clear / Write
 - Trigger Mode: Video or External

Step 2:

- Configure the UUT for normal transmissions with a sufficiently high payload (transmitter activity ratio $> 10\%$) to allow demonstration of compliance of the adaptive mechanism on the channel being tested.
- Using procedure defined in clause 5.3.8.3 (for measuring channel/frequency usage), it shall be verified that the UUT complies with the maximum *Channel Occupancy Time* defined in clause 4.2.5.3. It shall also be verified (if necessary by repeating the test) that the measured *Idle Period* is greater or equal to the initial CCA observation time as defined in clause 4.2.5.2.

Step 3: Adding the interference signal

- A 100 % duty cycle interference signal is injected on the current operating channel of the UUT. This interference signal shall be a CW signal. The total power level of this interference is to be set as defined in clause 4.2.5.3, step 6.

Step 4: Verification of reaction to the interference signal

- The analyser shall be used to monitor the transmissions of the UUT and the companion device on the selected operating channel after the interference signal was injected. This may require the analyser sweep to be triggered by the start of the interfering signal.
- Using the procedure defined in clause 5.3.8.3, it shall be verified that:
 - a) The UUT stops transmissions on the current operating channel. The UUT is assumed to stop transmissions within a period equal to the maximum *Channel Occupancy Time* defined in clause 4.2.5.3. The UUT is allowed to respond to transmissions of the companion device and the channel occupancy time shall be less than or equal to the maximum channel occupancy time on the current operating channel.
 - b) Apart from transmission of the frames for time synchronization and for beamforming, no frame shall be initiated.
 - c) The time synchronization and beam forming frames transmissions shall be less than or equal to 10 % within an observation period of 100 ms.
 - d) On removal of the interference signal the UUT may start transmissions again on this channel. However, this is not a requirement and, therefore, does not require testing.

Step 5:

- Step 2 to step 4 shall be repeated for each of the channels to be tested.

5.3.8.3 Generic test procedure for measuring channel/frequency usage

This is a generic test method to evaluate transmissions on the operating channel being investigated. It shall be performed as part of the main procedure in clause 5.3.8.2, step 4.

This test procedure shall be as follows:

Step 1:

- The analyser shall be set as follows:
 - Centre Frequency: Equal to the centre frequency of the channel being investigated
 - Frequency Span: 0 Hz
 - RBW: Approximately 50 % of the nominal channel bandwidth (if the analyser does not support this setting, 8 MHz minimum shall be used)
 - VBW: $3 \times$ RBW (if the analyser does not support this setting, the highest available setting shall be used)
 - Detector Mode: RMS
 - Sweep time: $>$ Channel Occupancy Time
 - Number of sweep points: Minimum 1 point per μ s

The time resolution has to be sufficient to meet the maximum measurement uncertainty for the period to be measured. In most cases, 1 μ s is the shortest period to be measured and thereby defining the time resolution.

- Trace mode: Clear / Write
- Trigger: Video or External

Step 2:

- Orientate UUT so that it is pointing at measurement antennas with its higher EIRP as measured during EIRP measurement.
- Position and orientate the companion device antenna in alignment with UUT and measurement antennas.
- Save the trace data of both sides to a file for further analysis by a computing device using an appropriate software application or program.

Step 3:

- Oscilloscope channel 1 is directed towards companion device and channel 2 to UUT.
- Identify the data points related to both channels being investigated as referred in figure 3 by applying a threshold.
- Investigate idle periods.
- At the end of each idle period, investigate the transmissions initiating device.
- For the UUT initiating transmissions, calculate the percentage of occupied time per period of 100 ms.
- Repeat step 3 for all idle periods within the measurement window.

Figure 3: Channel 1 / 2 chronogram

5.3.9 Transmitter unwanted emissions in the out-of-band domain

5.3.9.1 Test conditions

These measurements need only to be performed at normal test conditions.

The device shall be configured to operate at its maximum output power level.

Radiated measurement shall be performed in an anechoic chamber or open air test site, see annex C.

5.3.9.2 Test method

The transmitter unwanted emissions in the out-of-band domain shall be measured using applicable measurement procedures in annex D for conformance with the requirements in clause 4.2.8.

The transmitter unwanted emissions in the out-of-band domain shall be determined using a spectrum analyser of adequate bandwidth for the type of modulation being used in combination with a RF power meter.

For the purpose of this test, the minimum transmitter on time shall be 10 μ s. For equipment where the transmitter on time is less than 10 μ s, the method of measurement shall be documented in the test report.

The test procedure shall be as follows:

Step 1:

The spectrum analyser shall use the following settings:

- a) Start/Stop frequencies: As needed per figure 1.
- b) Resolution bandwidth: 1 MHz.
- c) Video bandwidth: 3 MHz.
- d) Sweep time: 1 minute.
- e) Detector: RMS Average, Sample, or Average (excepting Video Average).
- f) Trace mode: Max hold.

Step 2:

When the trace is complete, capture the trace, for example, using the "View" option on the spectrum analyser.

Find the peak value of the trace and place the analyser marker on this peak. The value from the above corrected by the observed duty cycle x , according to the formula in clause 5.3.3, step 4 shall be recorded in the test report.

5.3.10 Occupied Channel Bandwidth

5.3.10.1 Test conditions

These measurements need only to be performed at normal test conditions

The device shall be configured to operate at its maximum output power level.

Radiated measurement shall be performed in an anechoic chamber or open air test site, see annex C.

5.3.10.2 Test method

The Occupied Channel Bandwidth shall be measured using applicable measurement procedures in annex D for conformance with the requirements in clause 4.2.10.

The Occupied Channel Bandwidth shall be determined using a spectrum analyser of adequate bandwidth for the type of modulation being used in combination with a RF power meter.

For the purpose of this test, the minimum transmitter on time shall be 10 μ s. For equipment where the transmitter on time is less than 10 μ s, the method of measurement shall be documented in the test report.

The test procedure shall be as follows:

Step 1:

The spectrum analyser shall use the following settings:

- g) Start/Stop frequencies: As needed per figure 1.
- h) Resolution bandwidth: 1 MHz.
- i) Video bandwidth: 3 MHz.
- j) Sweep time: 1 minute.
- k) Detector: RMS Average, Sample, or Average (excepting Video Average).
- l) Trace mode: Max hold.

Step 2:

When the trace is complete, capture the trace, for example, using the "View" option on the spectrum analyser.

Use the 99 % bandwidth function of the spectrum analyser to measure the Occupied Channel Bandwidth. This value shall be recorded.

Annex A (informative): Relationship between the present document and the essential requirements of Directive 2014/53/EU

The present document has been prepared under the Commission's standardisation request C(2015) 5376 final [i.2] to provide one voluntary means of conforming to the essential requirements of Directive 2014/53/EU on the harmonisation of the laws of the Member States relating to the making available on the market of radio equipment and repealing Directive 1999/5/EC [i.6].

Once the present document is cited in the Official Journal of the European Union under that Directive, compliance with the normative clauses of the present document given in table A.1 confers, within the limits of the scope of the present document, a presumption of conformity with the corresponding essential requirements of that Directive, and associated EFTA regulations.

**Table A.1: Relationship between the present document
and the essential requirements of Directive 2014/53/EU**

Harmonised Standard ETSI EN 302 567				
Requirement			Requirement Conditionality	
No	Description	Reference: Clause No	U/C	Condition
1	Spectral power density	4.2.1	U	
2	RF output power	4.2.2	U	
3	Transmitter unwanted emissions	4.2.3	U	
4	Receiver unwanted emissions	4.2.4	U	
5	Adaptivity (Medium access protocol)	4.2.5	U	
6	Receiver Adjacent Channel Rejection	4.2.7	U	
7	Transmitter unwanted emissions in the out-of-band domain	4.2.8	U	
8	Geo Location	4.2.9	C	Applies only to equipment with geo-location capability
9	Occupied Channel Bandwidth	4.2.10	U	

Key to columns:

Requirement:

No A unique identifier for one row of the table which may be used to identify a requirement.

Description A textual reference to the requirement.

Clause Number Identification of clause(s) defining the requirement in the present document unless another document is referenced explicitly.

Requirement Conditionality:

U/C Indicates whether the requirement is unconditionally applicable (U) or is conditional upon the manufacturer's claimed functionality of the equipment (C).

Condition Explains the conditions when the requirement is or is not applicable for a requirement which is classified "conditional".

Presumption of conformity stays valid only as long as a reference to the present document is maintained in the list published in the Official Journal of the European Union. Users of the present document should consult frequently the latest list published in the Official Journal of the European Union.

Other Union legislation may be applicable to the product(s) falling within the scope of the present document.

Annex B:
Void

Annex C (normative): Test sites and arrangements for radiated measurements

C.1 Test sites

C.1.1 Open air test sites

The term "open air" should be understood from an electromagnetic point of view. Such a test site may be really in open air or alternatively with walls and ceiling transparent to the radio waves at the frequencies considered.

An open air test site may be used to perform the measurements using the radiated measurement methods described in clause 5.3. Absolute or relative measurements may be performed on transmitters or on receivers; absolute measurements of field strength require a calibration of the test site.

A measuring distance of at least 3 m shall be used for measurements at frequencies up to 1 GHz. For frequencies above 1 GHz, any suitable measuring distance may be used. The equipment size (excluding the antenna) shall be less than 20 % of the measuring distance. The height of the equipment or of the substitution antenna shall be 1,5 m; the height of the test antenna (transmit or receive) shall vary between 1 m and 4 m.

Sufficient precautions shall be taken to ensure that reflections from extraneous objects adjacent to the site do not degrade the measurement results, in particular:

- no extraneous conducting objects having any dimension in excess of a quarter wavelength of the highest frequency tested shall be in the immediate vicinity of the site;
- all cables shall be as short as possible; as much of the cables as possible shall be on the ground plane or preferably below; and the low impedance cables shall be screened.

The general measurement arrangement is shown in figure C.1.

- 1) Equipment under test.
- 2) Test antenna.
- 3) High pass filter (as required).
- 4) Spectrum analyser or measuring receiver.

Figure C.1: Measuring arrangement

C.1.2 Anechoic chamber

C.1.2.1 General

An anechoic chamber is a well shielded chamber covered inside with radio frequency absorbing material and simulating a free space environment. It is an alternative site on which to perform the measurements using the radiated measurement methods described in clause 5.3. Absolute or relative measurements may be performed on transmitters or on receivers. Absolute measurements of field strength require a calibration of the anechoic chamber. The test antenna, equipment under test and substitution antenna are used in a way similar to that at the open air test site, but are all located at the same fixed height above the floor.

C.1.2.2 Description

An anechoic chamber should meet the requirements for shielding loss and wall return loss as shown in figure C.2. Figure C.3 shows an example of the construction of an anechoic chamber having a base area of 5 m by 10 m and a height of 5 m. The ceiling and walls are coated with pyramidally formed absorbers approximately 1 m high. The base is covered with special absorbers which form the floor. The available internal dimensions of the chamber are 3 m × 8 m × 3 m, so that a maximum measuring distance of 5 m in the middle axis of this chamber is available. The floor absorbers reject floor reflections so that the antenna height need not be changed. Anechoic chambers of other dimensions may be used. Alternatively, an anechoic chamber having a base area of 2,5 m × 3 m and a height of 5 m may also be used.

C.1.2.3 Influence of parasitic reflections

For free-space propagation in the far field, the relationship of the field strength E and the distance R is given by $E = E_o \times (R_o / R)$, where E_o is the reference field strength and R_o is the reference distance. This relationship allows relative measurements to be made as all constants are eliminated within the ratio and neither cable attenuation nor antenna mismatch or antenna dimensions are of importance.

If the logarithm of the foregoing equation is used, the deviation from the ideal curve may be easily seen because the ideal correlation of field strength and distance appears as a straight line. The deviations occurring in practice are then clearly visible. This indirect method shows quickly and easily any disturbances due to reflections and is far less difficult than the direct measurement of reflection attenuation.

With an anechoic chamber of the dimensions given above at low frequencies below 100 MHz there are no far field conditions, but the wall reflections are stronger, so that careful calibration is necessary. In the medium frequency range from 100 MHz to 1 GHz the dependence of the field strength to the distance meets the expectations very well. Above 1 GHz, because more reflections will occur, the dependence of the field strength to the distance will not correlate so closely.

C.1.2.4 Calibration and mode of use

The calibration and mode of use is the same as for an open air test site, the only difference being that the test antenna does not need to be raised and lowered whilst searching for a maximum, which simplifies the method of measurement.

Figure C.2: Specification for shielding and reflections

Figure C.3: Anechoic shielded chamber for simulated free space measurements

C.2 Test antenna

When the test site is used for radiated measurements the test antenna shall be used to detect the field from both the test sample and the substitution antenna. When the test site is used for the measurement of receiver characteristics the antenna shall be used as a transmitting antenna. This antenna shall be mounted on a support capable of allowing the antenna to be used in either horizontal or vertical polarization and for the height of its centre above the ground to be varied over the specified range. Preferably test antennae with pronounced directivity should be used. The size of the test antenna along the measurement axis shall not exceed 20 % of the measuring distance. The antenna shall include any necessary up/down conversion to an intermediate frequency for practical signal transport to/from related test equipment.

C.3 Substitution antenna

The substitution antenna shall be used to replace the equipment under test in substitution measurements. For measurements below 1 GHz the substitution antenna shall be a half wavelength dipole resonant at the frequency under consideration, or a shortened dipole, calibrated to the half wavelength dipole. For measurements between 1 GHz and 4 GHz either a half wavelength dipole or a horn radiator may be used. For measurements above 4 GHz a horn radiator shall be used. The centre of this antenna shall coincide with the reference point of the test sample it has replaced. This reference point shall be the volume centre of the sample when its antenna is mounted inside the cabinet, or the point where an outside antenna is connected to the cabinet.

The distance between the lower extremity of the dipole and the ground shall be at least 30 cm.

NOTE: The gain of a horn antenna is generally expressed relative to an isotropic radiator.

Annex D (normative): General description of measurement

D.1 Radiated measurements

Radiated measurements shall be performed with the aid of a test antenna and measurement instruments as described in annex C. The test antenna and measurement instrument shall be calibrated according to the procedure defined in this annex. The equipment to be measured and the test antenna shall be oriented to obtain the maximum emitted power level. This position shall be recorded in the measurement report. The frequency range shall be measured in this position.

Preferably, radiated measurements shall be performed in an anechoic chamber. For other test sites corrections may be needed (see annex C). The following test procedure applies:

- a) A test site which fulfils the requirements of the specified frequency range of this measurement shall be used. The test antenna shall be oriented initially for vertical polarization unless otherwise stated and the transmitter under test shall be placed on the support in its standard position (clause C.1.1) and switched on.
- b) For average power measurements a non-selective voltmeter or wide band spectrum analyser shall be used. For other measurements a spectrum analyser or selective voltmeter shall be used and tuned to the measurement frequency.

In either case a) or case b), the test antenna shall be raised or lowered, if necessary, through the specified height range until the maximum signal level is detected on the spectrum analyser or selective voltmeter.

The test antenna need not be raised or lowered if the measurement is carried out on a test site according to clause C.1.2.

- 1) Equipment under test.
- 2) Test antenna.
- 3) Spectrum analyser or measuring receiver.

Figure D.1: Measurement arrangement No.1

- c) The transmitter shall be rotated through 360° about a vertical axis until a higher maximum signal is received.
- d) The test antenna shall be raised or lowered again, if necessary, through the specified height range until a maximum is obtained. This level shall be recorded. This maximum may be a lower value than the value obtainable at heights outside the specified limits. The test antenna need not be raised or lowered if the measurement is carried out on a test site according to clause C.1.2. This measurement shall be repeated for horizontal polarization.

D.2 Substitution measurement

The actual signal generated by the measured equipment may be determined by means of a substitution measurement in which a known signal source replaces the device to be measured, see figure D.2.

Preferably, this method of measurement shall be used in an anechoic chamber. For other test sites corrections may be needed, see annex C.

- 1) Substitution antenna.
- 2) Test antenna.
- 3) Spectrum analyser or selective voltmeter.
- 4) Signal generator.

Figure D.2: Measurement arrangement No.2

- a) Using measurement arrangement No.2, the substitution antenna shall replace the transmitter antenna in the same position and in vertical polarization. The frequency of the signal generator shall be adjusted to the measurement frequency. The test antenna shall be raised or lowered, if necessary, to ensure that the maximum signal is still received. The input signal to the substitution antenna shall be adjusted in level until an equal or a known related level to that detected from the transmitter is obtained in the test receiver:
 - the test antenna need not be raised or lowered if the measurement is carried out on a test site according to clause C.1.2;
 - the radiated power is equal to the power supplied by the signal generator, increased by the known relationship if necessary and after corrections due to the gain of the substitution antenna and the cable loss between the signal generator and the substitution antenna.
- b) This measurement shall be repeated with horizontal polarization.

For test sites with a fixed setup of the measurement antenna(s) and a reproducible positioning of the UUT, correction values from a verified site calibration can be used alternatively.
