Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://webapp.etsi.org/IPR/home.asp>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This European Standard (EN) has been produced by Joint Technical Committee (JTC) Broadcast of the European Broadcasting Union (EBU), Comité Européen de Normalisation ELECtrotechnique (CENELEC) and the European Telecommunications Standards Institute (ETSI).

NOTE: The EBU/ETSI JTC Broadcast was established in 1990 to co-ordinate the drafting of standards in the specific field of broadcasting and related fields. Since 1995 the JTC Broadcast became a tripartite body by including in the Memorandum of Understanding also CENELEC, which is responsible for the standardization of radio and television receivers. The EBU is a professional association of broadcasting organizations whose work includes the co-ordination of its members' activities in the technical, legal, programme-making and programme-exchange domains. The EBU has active members in about 60 countries in the European broadcasting area; its headquarters is in Geneva.

The Digital Video Broadcasting Project (DVB) is an industry-led consortium of broadcasters, manufacturers, network operators, software developers, regulatory bodies, content owners and others committed to designing global standards for the delivery of digital television and data services. DVB fosters market driven solutions that meet the needs and economic circumstances of broadcast industry stakeholders and consumers. DVB standards cover all aspects of digital television from transmission through interfacing, conditional access and interactivity for digital video, audio and data. The consortium came together in 1993 to provide global standardisation, interoperability and future proof specifications.

National transposition dates	
Date of adoption of this EN:	18 April 2011
Date of latest announcement of this EN (doa):	31 July 2011
Date of latest publication of new National Standard or endorsement of this EN (dop/e):	31 January 2012
Date of withdrawal of any conflicting National Standard (dow):	31 January 2012

1 Scope

The present document describes a second generation baseline transmission system for digital television broadcasting via Hybrid Fibre Coax (HFC) cable networks and Master Antenna Television (MATV) installations. It specifies the channel coding, modulation and lower layer signalling protocol system intended for the provision of digital television services and generic data streams.

The scope is as follows:

- it gives a general description of the Baseline System for digital cable TV;
- it specifies the digital signal processing in order to establish compatibility between pieces of equipment developed by different manufacturers. This is achieved by describing in detail the signal processing at the transmitting side, while the processing at the receiving side is left open to individual implementations. However, for the purpose of securing interoperability it is necessary in this text to refer to certain implementation aspects of the receiving end.

DVB-C [i.4] was introduced as a European Norm in 1994. It specifies single carrier QAM modulation and Reed-Solomon channel coding and is used today by many cable operators worldwide for television and data broadcasting as well as for forward channel transmission of the Data Over Cable System defined in [i.7].

Since 1994 enhanced digital transmission technologies have evolved somewhat:

- New channel coding schemes, combined with higher order modulation, promise more powerful alternatives to the DVB-C coding and modulation schemes. The result is a capacity gain in the order of 30 % at a given cable channel bandwidth and CATV network performance.
- Variable Coding and Modulation (VCM) may be applied to provide different levels of error protection to different services (e.g. SDTV and HDTV, audio, multimedia).
- In the case of interactive and point-to-point applications, the VCM functionality may be combined with the use of return channels, to achieve Adaptive Coding and Modulation (ACM). This technique provides more exact channel protection and dynamic link adaptation to propagation conditions, targeting each individual receiving terminal.
- DVB-C is strictly focused on a unique data format, the MPEG Transport Stream (ISO/IEC 13818-1 [i.1] or a reference to it). Extended flexibility to cope with other input data formats (such as multiple Transport Streams, or generic data formats) is now possible without significant complexity increase.

The present document defines a "second generation" modulation and channel coding system (denoted the "C2 System" or "DVB-C2" for the purposes of the present document) to make use of the improvements listed above. DVB-C2 is a single, very flexible standard, covering a variety of applications by cable, as described below. It is characterized by:

- a flexible input stream adapter, suitable for operation with single and multiple input streams of various formats (packetized or continuous);
- a powerful FEC system based on LDPC (Low-Density Parity Check) codes concatenated with BCH (Bose Chaudhuri Hocquenghem) codes, allowing Quasi Error Free operation close to the Shannon limit, depending on the transmission mode (AWGN channel, modulation constrained Shannon limit);
- a wide range of code rates (from 2/3 up to 9/10); 5 constellations, ranging in spectrum efficiency from 1 to 10,8 bit/s/Hz, optimized for operation in cable networks;
- Adaptive Coding and Modulation (ACM) functionality, optimizing channel coding and modulation on a frame-by-frame basis.

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

⊕: Exclusive OR / modulo-2 addition operation

0xkk: digits 'kk' should be interpreted as a hexadecimal number

active cell: OFDM Cell carrying a constellation point for L1 signalling or a PLP

auxiliary data: sequence of cells carrying data of as yet undefined modulation and coding, which may be used for stuffing Data Slices or stuffing Data Slice Packets

BBFrame: signal format of an input signal after mode and stream adaptation

BBHeader: header in front of a baseband data field

NOTE: See clause 5.1.

BUFS: maximum size of the requested receiver buffer to compensate delay variations

BUFSTAT: actual status of the receiver buffer

C2 frame: fixed physical layer TDM frame that is further divided into variable size Data Slices

NOTE: C2 Frame starts with one or more Preamble Symbol.

C2 system: complete transmitted DVB-C2 signal, as described in the L1-part2 block of the related Preamble

common PLP: special PLP, which contains data shared by multiple PLPs (Transport Stream)

data cell: OFDM Cell which is not a pilot or tone reservation cell

data PLP: PLP carrying payload data

data slice: group of OFDM Cells carrying one or multiple PLPs in a certain frequency sub-band

NOTE: This set consists of OFDM Cells within a fixed range of consecutive cell addresses within each Data Symbol and spans over the complete C2 Frame, except the Preamble Symbols.

data slice packet: XFECFrame including the related FECFrame Header

data symbol: OFDM Symbol in a C2 Frame which is not a Preamble Symbol

div: integer division operator, defined as:

$$x \text{ div } y = \left\lfloor \frac{x}{y} \right\rfloor$$

dummy cell: OFDM Cell carrying a pseudo-random value used to fill the remaining capacity not used for L1 signalling, PLPs or Auxiliary Data

elementary period: time period which depends on the channel raster and is used to define the other time periods in the C2 System

FECFrame: set of N_{LDPC} (16 200 or 64 800) bits of one LDPC encoding operation

NOTE: In case of Data Slices carrying a single PLP and constant modulation and encoding is applied, FECFrame Header information may be carried in Layer1 part2 and the Data Slice Packet is identical with the XFECFrame.

FFT size: nominal FFT size for a DVB-C2 receiver is 4K

NOTE: Further details are discussed in clause 10.1.

for i=0..xxx-1: when used with the signalling loops, this means that the corresponding signalling loop is repeated as many times as there are elements of the loop

NOTE: If there are no elements, the whole loop is omitted.

Im(x): Imaginary part of x

Layer 1 (L1): name of the first layer of the DVB-C2 signalling scheme (signalling of physical layer parameters)

L1 block: set of L1-part2 COFDM Cells, cyclically repeated in the frequency domain

NOTE: L1 Blocks are transmitted in the Preamble.

L1-part1: signalling carried in the header of the Data Slice Packets carrying modulation and coding parameters of the related XFECFrame

NOTE: L1-part1 parameters may change per XFECFrame.

L1-part2: Layer 1 Signalling cyclically transmitted in the preamble carrying more detailed L1 information about the C2 System, Data Slices, Notches and the PLPs

NOTE: L1-part2 parameters may change per C2 Frame.

Layer 2 (L2): name of the second layer of the DVB-C2 signalling scheme (signalling of transport layer parameters)

mod: modulo operator, defined as:

$$x \bmod y = x - y \left\lfloor \frac{x}{y} \right\rfloor$$

mode adapter: input signal processing block, delivering BBFrames at its output

nnD: digits 'nn' should be interpreted as a decimal number

notch: set of adjacent OFDM Cells within each OFDM Symbol without transmitted energy

null packet: MPEG Packet with the Packet_ID 0x1FFF, carrying no payload data and intended for padding

OFDM cell: modulation value for one OFDM carrier during one OFDM Symbol, e.g. a single constellation point

OFDM symbol: waveform Ts in duration comprising all the active carriers modulated with their corresponding modulation values and including the guard interval

Physical Layer Pipe (PLP): logical channel carried within one or multiple Data Slice(s)

NOTE 1: All signal components within a PLP share the same transmission parameters such as robustness, latency.

NOTE 2: A PLP may carry one or multiple services. In case of PLP Bundling a PLP may be carried in several Data Slices. Transmission parameters may change each XFECFrame.

PLP bundling: transmission of one PLP via multiple Data Slices

PLP_ID: this 8-bit field identifies uniquely a PLP within a C2 transmission signal

preamble header: fixed size signalling transmitted in the first part of the Preamble, carrying the length and Interleaving parameters of Layer 1 part 2 data

preamble symbol: one or multiple OFDM Symbols, transmitted at the beginning of each C2 Frame, carrying Layer 1 part 2 signalling data

Re(x): Real part of x

reserved for future use: value of any field indicated as "reserved for future use" shall be set to "0" unless otherwise defined

START_FREQUENCY: index of lowest used OFDM subcarrier of a C2 System. The value of START_FREQUENCY shall be a multiple of D_X

x^* : Complex conjugate of x

XFECFrame: FECFrame mapped onto QAM constellations:

- $\lfloor x \rfloor$: round towards minus infinity: the most positive integer less than or equal to x.
- $\lceil x \rceil$: round towards plus infinity: the most negative integer greater than or equal to x.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

Δ	Absolute guard interval duration
A	LDPC codeword of size N_{ldpc}
λ_i	LDPC codeword bits
λ^{RM}	32 output bits of Reed-Muller encoder
λ_i^{RM}	Bit number of index i of 32 bit long output bits of Reed-Muller encoder
$\eta_{MOD}, \eta_{MOD}(i)$	Number of transmitted bits per constellation symbol (for PLP i)
π_p	Permutation operator defining parity bit groups to be punctured for L1 signalling
π_s	Permutation operator defining bit-groups to be padded for L1 signalling
$A_{m,l}$	Output vector of the frequency interleaver of OFDM Symbol l and C2 Frame m
A_{CP}	Amplitude of the continual pilot cells
A_{SP}	Amplitude of the scattered pilot cells
$a_{m,l,q}$	Frequency-Interleaved cell value, cell index q of symbol l of C2 Frame m
$B(n)$	Location of the first Data Cell of symbol 1 allocated to Data Slice n in the frequency interleaver
b	16 bit long FECFrame signalling data vector
$b_{e,do}$	Output from the demultiplexer, depending on the demultiplexed bit sub-stream number e and the input bit number d_i of the bit interleaver demultiplexer
b_i	Bit number of index i of 16 bit long FECFrame signalling data vector
C/N	Carrier-to-noise power ratio
$C/N+I$	Carrier-to-(Noise+Interference) ratio
C_i	Column of index i of time interleaver
c_i	Column of index i of bit interleaver
$c(x)$	Equivalent BCH codeword polynomial
$c_{m,l,k}$	Cell value for carrier k of symbol l of C2 Frame m
DFL	Data field length
D_P	Difference in carrier index between adjacent preamble-pilot-bearing carriers
D_x	Difference in carrier index between adjacent scattered-pilot-bearing carriers
D_y	Difference in symbol number between successive scattered pilots on a given carrier
$d(x)$	Remainder of dividing message polynomial by the generator polynomial $g(x)$ during BCH encoding
d_i	Input bit number d_i of the bit interleaver demultiplexer
d_o	Bit number of a given stream at the output of the demultiplexer of the bit interleaver
e	Demultiplexed bit sub stream number ($0 \leq e < N_{\text{substreams}}$), depending on input bit number d_i of the bit interleaver demultiplexer
f_q	Constellation point normalized to mean energy of 1
G	Reed-Muller encoder matrix
$g(x)$	BCH generator polynomial

$g_1(x), g_2(x), \dots, g_{12}(x)$	Polynomials to obtain BCH code generator polynomial
g_q	Complex cell of index q of a Data Slice Packet
$H(q)$	Frequency interleaver permutation function, element q
I	Output codeword of BCH encoder
i_j	BCH codeword bits which form the LDPC information bits
j	$\sqrt{-1}$
K_{bch}	Number of bits of BCH uncoded Block
K_i	L1 signalling part 2 parameter selected as $N_{L1part2}(K_i) \leq N_{L1part2_Cells} \times \eta_{\text{MOD}}$
K_{ldpc}	Number of bits of LDPC uncoded Block
$K_{L1_PADDING}$	Length of L1_PADDING field
$K_{L1part2}$	Length of L1-part2 signalling field including the padding field
$K_{L1part2_ex_pad}$	Number of information bits in L1-part2 signalling excluding the padding field
$K_{N,\min}$	Lowest frequency carrier index of a frequency Notch
$K_{N,\max}$	Highest frequency carrier index of a frequency Notch
K_{sig}	Number of signalling bits per FEC block for L1 signalling part 2
K_{\min}	Lowest frequency carrier index of a C2 signal, shall be identical to the START_FREQUENCY and shall be multiple of D_x
K_{\max}	Highest frequency carrier index of a C2 signal, shall be multiple of D_x
K_{total}	Number of OFDM carriers per OFDM symbol
k	Absolute OFDM carrier index
L_{data}	Number of data OFDM Symbols per C2 Frame (excluding Preamble)
L_F	Number of OFDM Symbols per C2 Frame including excluding preamble
L_P	Number of preamble OFDM Symbols within the C2 Frame
l	Index of OFDM Symbol within the C2 Frame (excluding preamble)
l_P	Index of preamble OFDM Symbol in C2 Frame
m	C2 Frame number
$m(x)$	Message polynomial within BCH encoding
m_i	Input bit of index i from uncoded bit vector M before BCH encoder
M	Uncoded bit vector before BCH encoder
M_{\max}	Maximum Sequence length for the frequency interleaver
N_{bch}	Number of bits of BCH coded Block
$N_{\text{bch_parity}}$	Number of BCH parity bits
N_c	Number of columns of bit or time interleaver
N_{data}	Number of Data Cells in a Data Slice in frequency interleaver
N_{DP}	Number of complex cells per Data Slice Packet
N_{group}	Number of bit-groups for BCH shortening
$N_{L1part2}$	Length of punctured and shortened LDPC codeword for L1-part2 signalling
$N_{L1part2_Cells}$	Number of available cells for L1 signalling part 2 in one OFDM Symbol
$N_{L1part2_FEC_Block}$	Number of LDPC blocks for the L1 signalling part 2
$N_{L1part2_max_per_Symbol}$	Maximum number of L1 information bits for transmitting the encoded L1 signalling part 2 through one OFDM Symbol
$N_{L1_TI_Depth}$	Time interleaving depth for L1 signalling part 2
$N_{L1part2_temp}$	Intermediate value used in L1 puncturing calculation
N_{ldpc}	Number of bits of LDPC coded Block
$N_{\text{MOD_per_Block}}$	Number of modulated cells per FEC block for the L1-part2 signalling
$N_{\text{MOD_Total}}$	Total number of modulated cells for the L1-part2 signalling
N_{pad}	Number of BCH bit-groups in which all bits will be padded for L1-part2 signalling
N_{punc}	Number of LDPC parity bits to be punctured
$N_{\text{punc_groups}}$	Number of parity groups in which all parity bits are punctured for L1 signalling
$N_{\text{punc_temp}}$	Intermediate value used in L1 puncturing calculation
N_r	Number of bits in Frequency Interleaver sequence
N_r	Number of rows of bit or time interleaver

N_{RT}	Number of reserved carriers
$N_{substreams}$	Number of substreams produced by the bit-to-sub-stream demultiplexer
n	Data slice number
$P_k(f)$	Power spectral density
p_i	LDPC parity bits
Q_{ldpc}	Code-rate dependent LDPC constant
q	Data Cell index within the OFDM Symbol prior to frequency interleaving and pilot insertion
$R_{eff_16K_LDPC_1_2}$	Effective code rate of 16K LDPC with nominal rate $\frac{1}{2}$
$R_{eff_L1part2}$	Effective code rate of L1-part2 signalling
R_i	Row of index i of time interleaver
R_i'	Value of element i of the frequency interleaver sequence following bit permutations
R'_i	Value of element i of the frequency interleaver sequence prior to bit permutations
r_i	Row of index i of bit interleaver
r_k	DBPSK modulated pilot reference sequence
S_0	List of reserved carriers
T	Elementary period
T_{Ci}	Column-twist value for column C of time interleaver
T_{CH}	Component set of carrier indices for reserved carriers
T_F	Duration of one C2 Frame
T_P	Time interleaving period
T_S	Total OFDM Symbol duration
T_U	Useful OFDM Symbol duration
t	BCH error correction capability
t_c	Column-twist value for column c of bit interleaver
U	Parity interleaver output
UPL	User Packet Length
u_i	Parity-interleaver output bits
u^{RM}	32 bit output vector of the cyclic delay block in the FECFrame header encoding
$u_{(i+2)mod32}^{RM}$	Output of the cyclic delay block for input bit i in the FECFrame header encoding
V	Column-twist interleaver output
v_i	Column-twist interleaver output bits
$v_{m,l,i}$	Output vector of frequency interleaver, starting at carrier index i (= Data slice start carrier) of the current OFDM Symbol l and C2 Frame m
v^{RM}	Scrambled output sequence in the lower branch of the FECFrame header encoder
v_i^{RM}	Bit i of scrambled output sequence in the lower branch of the FECFrame header encoder
w_i	Bit i of the data scrambling sequence
w^{RM}	32 bit scrambling sequence in the lower branch of the FECFrame header encoder
w_i^{RM}	Bit i of scrambling sequence in the lower branch of the FECFrame header encoder
w^P	Pilot synchronization sequence, build out of w_i and w'
w_k^P	Bit of index k of pilot synchronization sequence
w'	L1 block specific pilot synchronization sequence
w_i'	Bit of index k of L1 block specific pilot synchronization sequence
X_j	The set of bits in group j of BCH information bits for L1 shortening
$X_{m,l}$	Frequency interleaver input Data Cells of the OFDM Symbol l and the C2 Frame m
x	Address of the parity bit accumulator according to i_{360} in LDPC encoder
$y_{i,q}$	Bit i of cell word q from the bit-to-cell-word demultiplexer
z_q	Constellation point prior to normalization

The symbols s, t, i, j, k are also used as dummy variables and indices within the context of some clauses or equations.

In general, parameters which have a fixed value for a particular PLP for one processing block (e.g. C2 Frame, Interleaving Frame, TI-block) are denoted by an upper case letter. Simple lower-case letters are used for indices and dummy variables. The individual bits, cells or words processed by the various stages of the system are denoted by lower case letters with one or more subscripts indicating the relevant indices.

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

1024QAM	1024-ary Quadrature Amplitude Modulation
16QAM	16-ary Quadrature Amplitude Modulation
256QAM	256-ary Quadrature Amplitude Modulation
4096QAM	4096-ary Quadrature Amplitude Modulation
64QAM	64-ary Quadrature Amplitude Modulation
ACM	Adaptive Coding and Modulation
AWGN	Additive White Gaussian Noise
BB	BaseBand
BBFrame	BaseBand Frame
BCH	Bose-Chaudhuri-Hocquenghem multiple error correction binary block code
BCHFEC	BCH Forward Error Correction
BICM	Bit Interleaved Coding and Modulation
C/N	Carrier to noise ratio
C/N+I	Carrier to noise and intermodulation power ratio
CATV	Community Antenna Television
CBR	Constant Bit Rate
CCM	Constant Coding and Modulation
CRC	Cyclic Redundancy Check
D	Decimal notation
DBPSK	Differential Binary Phase Shift Keying
DEMUX	DEMUltipleXer
DFL	Data Field Length
DNP	Deleted Null Packets
DVB	Digital Video Broadcasting project
DVB-C	DVB System for cable transmission

NOTE: As defined in EN 300 429 [i.5].

DVB-C2	DVB-C2 System
--------	---------------

NOTE: As specified in the present document.

DVB-S	DVB System for digital broadcasting via satellites
-------	--

NOTE: As specified in EN 300 421 [i.8].

DVB-S2	Second Generation DVB System for satellite broadcasting
--------	---

NOTE: As specified in EN 302 307 [i.3].

DVB-T	DVB System for terrestrial broadcasting
-------	---

NOTE: As specified in EN 302 755 [i.6].

4 DVB-C2 System architecture

4.1 System overview

The generic C2 System model is represented in figure 1. The system input(s) may be one or more MPEG-2 Transport Stream(s) [i.1] and/or one or more Generic Stream(s) [i.2]. The Input pre-processor, which is not part of the C2 System, may include a service splitter or a demultiplexer for Transport Streams (TS) used to separate the services into the C2 System inputs, which are one or more logical data streams. These are then carried in individual Physical Layer Pipes (PLPs).

The system output is a single signal to be transmitted on a single RF channel.

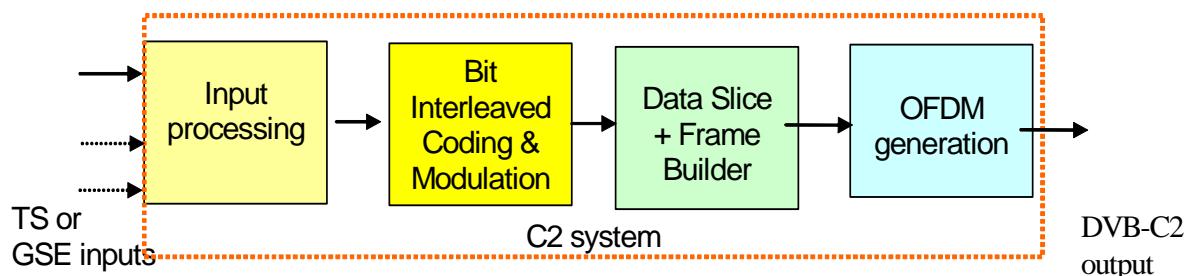

Figure 1: High level C2 block diagram

The input data streams shall be subject to the constraint that, over the duration of one physical-layer frame (C2 Frame), the total input data capacity (in terms of cell throughput, following Null Packet Deletion, if applicable, and after coding and modulation), shall not exceed the C2 available capacity (in terms of Data Cells, constant in time) of the C2 Frame for the current frame parameters. One or more PLPs are arranged in a group of PLPs and one or more of such groups of PLPs form a Data Slice. A C2 System may consist of one or more Data Slices. Each group of PLPs may contain one Common PLP, but a group of PLPs need not contain a Common PLP. When the DVB-C2 signal carries a single PLP there is no Common PLP. It is assumed that the receiver will always be able to receive one Data PLP and its associated Common PLP, if any.

More generally, the group of statistically multiplexed services can use Variable Coding and Modulation (VCM) for different services, provided they generate a constant total output capacity (i.e. in terms of cell rate including FEC and modulation).

When multiple input MPEG-2 TSs are transmitted via a group of PLPs, splitting of input TSs into TSPS streams (carried via the Data PLPs) and a TSPSC stream (carried via the associated Common PLP), as described in annex D, shall be performed immediately before the Input processing block shown in figure 1. This processing shall be considered an integral part of an extended DVB-C2 System.

4.2 System architecture

The C2 input processing block diagram is shown in figures 2, which is split into several parts. Figure 2(a) shows the input processing in case of multiple PLPs. Figure 2(a) shows the BICM module and figure 2(c) shows the frame builder module. Figure 2(d) shows the OFDM generation module.

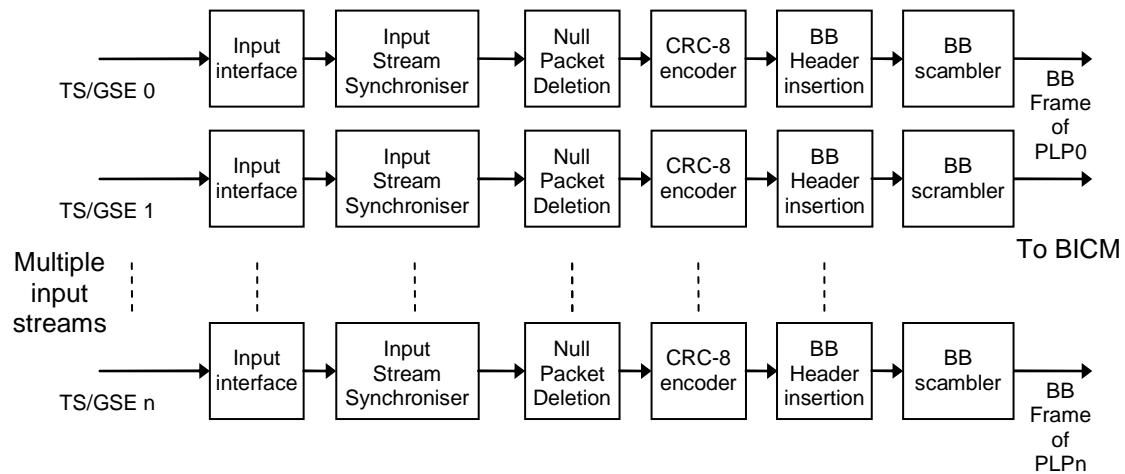

Figure 2(a): Mode adaptation for multiple input streams (PLP)

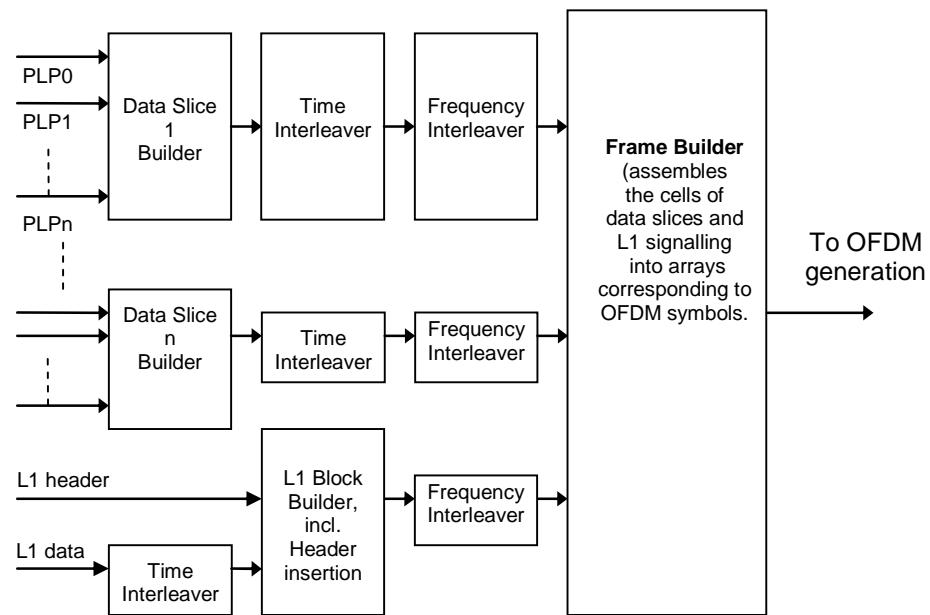

Figure 2(c): Data Slice + Frame builder

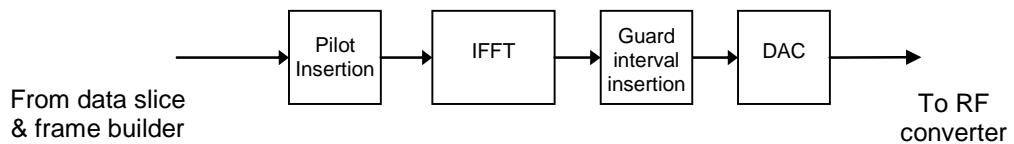

Figure 2(d): OFDM generation

Figure 2(e) combines the functions given in figures 2(a) to 2(d) in one simplified overall DVB-C2 block diagram.

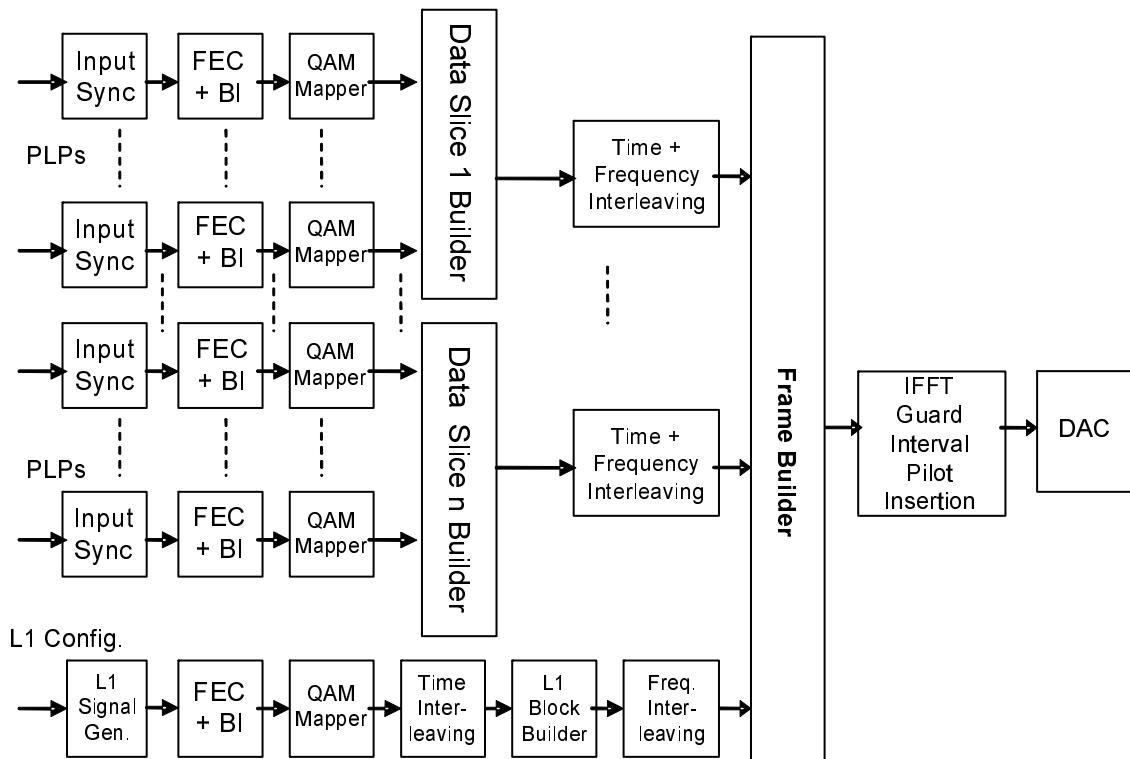

Figure 2(e): DVB-C2 modulator block diagram

4.3 Target performance

If the received signal is above the C/N+I threshold, the Forward Error Correction (FEC) technique adopted in the C2 System is designed to provide a "Quasi Error Free" (QEF) quality target. The definition of QEF adopted for DVB-C2 is "less than one uncorrected error-event per transmission hour at the level of a 5 Mbit/s single TV service decoder", corresponding to a Transport Stream Packet Error Rate of approximately PER < 10⁻⁷ measured at the input of the demultiplexer unit at the receiving end.

5 Input processing

5.1 Mode adaptation

The input to the C2 System shall consist of one or more logical data streams. One logical data stream is carried by one Physical Layer Pipe (PLP). The mode adaptation modules, which operate separately on the contents of each PLP, slice the input data stream into data fields which, after stream adaptation, will form baseband frames (BBFrame). The mode adaptation module comprises the input interface, followed by three optional sub-systems (the input stream synchronizer, the Null Packet deletion unit and the CRC-8 encoder) and then finishes by slicing the incoming data stream into data fields and inserting the baseband header (BBHeader) at the start of each data field. Each of these sub-systems is described in the following clauses.

Each input PLP may have one of the formats specified in clause 5.1.1. The mode adaptation module can process input data in one of two modes, normal mode (NM) or high efficiency mode (HEM). These modes are described in clauses 5.1.6 and 5.1.7 respectively. NM is in line with the Mode Adaptation in [i.3], whereas in HEM, further stream specific optimizations may be performed to reduce signalling overhead. The BBHeader (see clause 5.1.6) signals the input stream type and the processing mode.

5.1.1 Input Formats

The input signals in terms of either single or multiple streams (one connected to each Mode Adaptation Module) (see figure 1) shall be supplied to the Mode Adaptation Module(s). In the case of a Transport Stream (TS), the packet rate will be a constant value, although only a proportion of the packets may correspond to service data and the remainder may be Null Packets.

Each input stream (PLP) of the C2 System shall be associated with a modulation and FEC protection mode which is statically configurable.

Each input PLP may take one of the following formats:

- Transport Stream (TS).
- Generic Encapsulated Stream (GSE) [i.2].
- Generic Continuous Stream (GCS) (a variable length packet stream where the modulator is not aware of the packet boundaries).
- Generic Fixed-length Packetized Stream (GFPS); this form is retained for compatibility with DVB-S2, but it is expected that GSE would now be used instead.

A Transport Stream shall be characterized by User Packets (UP) of fixed length O-UPL = 188×8 bits (one MPEG TS packet), the first byte being a SYNC byte (47_{HEX}) and shall be signalled in the BBHeader TS/GS field, see clause 5.1.6.

A GSE stream shall be characterized by variable length packets or constant length packets, as signalled within GSE packet headers, and shall be signalled in the BBHeader by TS/GS field, see clause 5.1.6.

A GCS shall be characterized by a continuous bit-stream and shall be signalled in the BBHeader by TS/GS field and UPL = 0_D, see clause 5.1.6. A variable length packet stream where the modulator is not aware of the packet boundaries, or a constant length packet stream exceeding 64 kbit, shall be treated as a GCS, and shall be signalled in the BBHeader by TS/GS field as a GCS and UPL = 0_D, see clause 5.1.6.

A GFPS shall be a stream of constant-length User Packets (UP), with length O-UPL bits (maximum O-UPL value 64 K), and shall be signalled in the BBHeader TS/GS field, see clause 5.1.6. O-UPL is the Original User Packet Length. UPL is the transmitted User Packet Length, as signalled in the BBHeader.

5.1.2 Input Interface

The input interface sub-system shall map the input into internal logical-bit format. The first received bit will be indicated as the Most Significant Bit (MSB). Input interfacing is applied separately for each single Physical Layer Pipe (PLP), see figure 2(a).

The Input Interface shall read a data field, composed of DFL bits (Data Field Length), where:

$$0 \leq \text{DFL} \leq (K_{\text{bch}} - 80)$$

where K_{bch} is the number of bits protected by the BCH and LDPC codes (see clause 6.1).

The maximum value of DFL depends on the chosen LDPC code, carrying a protected payload of K_{bch} bits. The 10-byte (80 bits) BBHeader is appended to the front of the data field, and is also protected by the BCH and LDPC codes.

The input interface shall either allocate a number of input bits equally to the available data field capacity, thus breaking UPs in subsequent data fields (this operation being called "fragmentation"), or shall allocate an integer number of UPs within the data field (no fragmentation). The available data field capacity is equal to $K_{\text{bch}} - 80$. When the value of $\text{DFL} < K_{\text{bch}} - 80$, a padding field shall be inserted by the stream adapter (see clause 5.2) to complete the LDPC/BCH code block capacity.

5.1.3 Input Stream Synchronization (Optional)

Data processing in the DVB-C2 modulator may produce variable transmission delay on the user information. The Input Stream Synchronizer sub-system shall provide suitable means to guarantee Constant Bit Rate (CBR) and constant end-to-end transmission delay for any input data format. The use of the Input Stream Synchronizer subsystem is optional, except that it shall always be used for PLPs carrying transport streams where the number of FEC blocks per C2 Frame may vary. This process shall follow the specification given in annex C, which is similar to [i.3]. Examples of receiver implementation are given in annex G. This process will also allow synchronization of a single PLP travelling in different Data Slices, since the reference clock and the counter of the input stream synchronizers shall be the same (see annex F).

The ISSY field (Input Stream Synchronization, 2 bytes or 3 bytes) carries the value of a counter clocked at the modulator clock rate ($1/T$ where T is defined in clause 10.) and can be used by the receiver to regenerate the correct timing of the regenerated output stream. The ISSY field carriage shall depend on the input stream format and on the Mode, as defined in clauses 5.1.6 and 5.1.7 and figures 4 to 8. In Normal Mode the ISSY Field is appended to UPs for packetized streams. In High Efficiency Mode a single ISSY field is transmitted per BBFrame in the BBHeader, taking advantage that UPs of a BBFrame travel together, and therefore experience the same delay/jitter.

When the ISSY mechanism is not being used, the corresponding fields of the BBHeader, if any, shall be set to '0'.

A full description of the format of the ISSY field is given in annex C.

5.1.4 Null Packet Deletion (optional, for TS only, NM and HEM)

Transport Stream rules require that bit rates at the output of the transmitter's multiplexer and at the input of the receiver's demultiplexer are constant in time and the end-to-end delay is also constant. For some Transport Stream input signals, a large percentage of Null Packets may be present in order to accommodate variable bit-rate services in a constant bit-rate TS. In this case, in order to avoid unnecessary transmission overhead, TS Null Packets shall be identified (PID = 8191_D) and removed. The process is carried out in a way that the removed Null Packets can be re-inserted in the receiver in the exact place where they were originated, thus guaranteeing a constant bit rate and avoiding the need for time stamp (PCR) updating.

When Null Packet Deletion is used useful packets (i.e. TS packets with $\text{PID} \neq 8191_D$), including the optional ISSY appended field shall be transmitted while Null Packets (i.e. TS packets with $\text{PID} = 8191_D$, including the optional ISSY appended field may be removed (see figure 3).

After transmission of a UP, a counter called DNP (Deleted Null Packets, 1 byte) shall be first reset and then incremented at each deleted Null Packet. When DNP reaches the maximum allowed value $DNP = 255_D$, then if the following packet is again a Null Packet this Null Packet is kept as a useful packet and transmitted.

Insertion of the DNP field (1 byte) shall be after each transmitted UP according to clause 5.17 and figure 3.

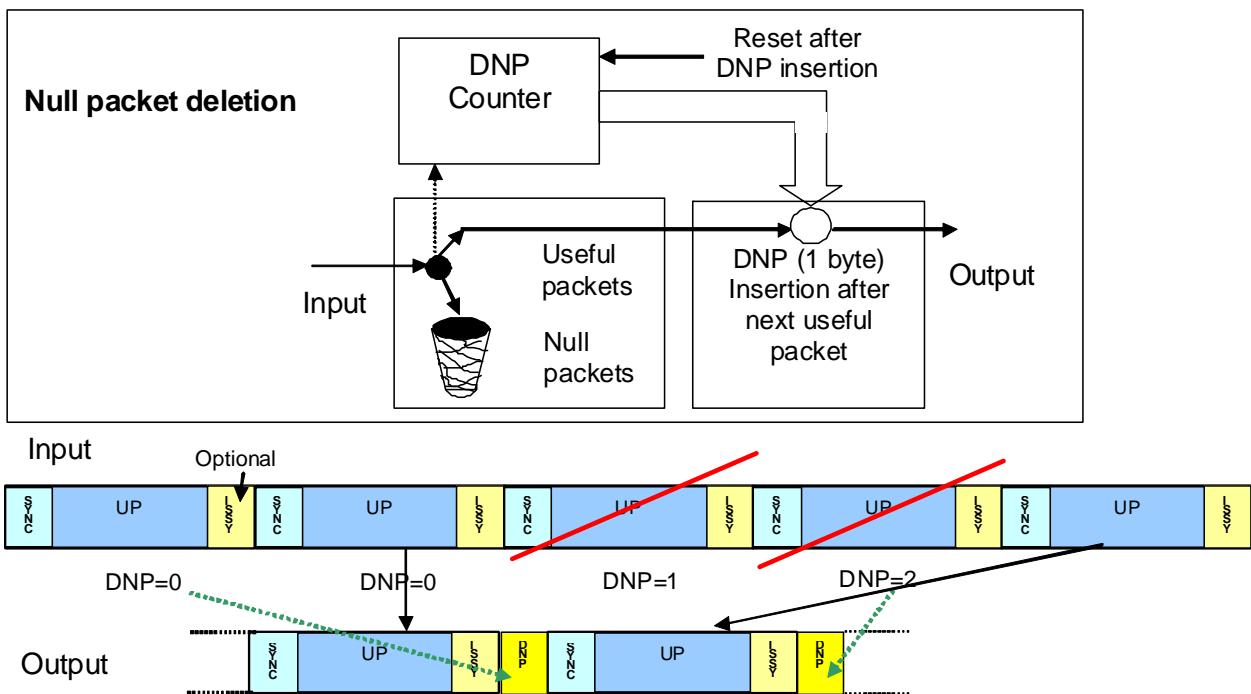

Figure 3: Null Packet deletion scheme

5.1.5 CRC-8 encoding (for GFPS and TS, NM only)

CRC-8 is applied for error detection at UP level (Normal Mode and packetized streams only). When applicable (see clause 5.1.7), the UPL minus 8 bits of the UP (after SYNC byte removal, when applicable) shall be processed by the systematic 8-bit CRC-8 encoder defined in annex E. The computed CRC-8 shall be appended after the UP according to clause 5.1.7.

5.1.6 Baseband Header (BBHeader) insertion

A fixed length BBHeader of 10 bytes shall be inserted in front of the baseband data field in order to describe the format of the data field. The BBHeader shall take one of two forms as shown in figure 4(a) for Normal Mode (NM) and in figure 4(b) for High Efficiency Mode (HEM). The current mode (NM or HEM) may be detected by the MODE field (EXORed with the CRC-8 field).

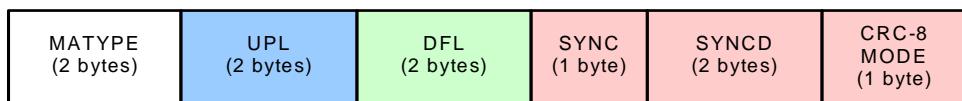

Figure 4(a): BBHeader format (NM)

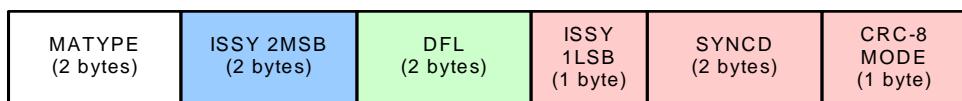

Figure 4(b): BBHeader format (HEM)

MATYPE (2 bytes): describes the input stream format and the type of Mode Adaptation as explained in table 1.

The use of the bits of the MATYPE field is described below.

First byte (MATYPE-1):

- TS/GS field (2 bits), Input Stream Format: Generic Packetized Stream (GFPS); Transport Stream; Generic Continuous Stream (GCS); Generic Encapsulated Stream (GSE).
- SIS/MIS field (1 bit): Single or Multiple Input Streams (referred to the global signal, not to each PLP).
- CCM/ACM field (1 bit): Constant Coding and Modulation or Variable/Adaptive Coding and Modulation.
- ISSYI (1 bit), (Input Stream Synchronization Indicator): If ISSYI = 1 = active, the ISSY field shall be computed (see annex C) and inserted according to clause 5.1.7.
- NPD (1 bit): Null Packet deletion active/not active. If NPD active, then DNP shall be computed and appended after UPs.
- EXT (2 bits), media specific (for C2, EXT=0: reserved for future use).

Table 1: MATYPE-1 field mapping

TS/GS (2 bits)	SIS/MIS (1 bit)	CCM/ACM (1 bit)	ISSYI (1 bit)	NPD (1 bit)	EXT (2 bits)
00 = GFPS	1 = single	1 = CCM	1 = active	1 = active	Reserved for future use
11 = TS	0 = multiple	0 = ACM	0 = not-active	0 = not-active	
01 = GCS					
10 = GSE					

NOTE 1: For C2, EXT=reserved for future use and for S2, EXT=RO =transmission roll-off.
 NOTE 2: For compatibility with DVB-S2 [i.3], when GSE is used with normal mode, it shall be treated as a Continuous Stream and indicated by TS/GS = 01.

Second byte (MATYPE-2):

- If SIS/MIS = Multiple Input Stream, then second byte = Input Stream Identifier (ISI); else second byte = '0' (reserved for future use).

NOTE: The term ISI is retained here for compatibility with DVB-S2 [i.3], but has the same meaning as the term PLP_ID which is used throughout the present document.

The use of the remaining fields of the BBHeader is described in table 2.

Table 2: Description of the fields of the BBHeader

Field	Size (Bytes)	Description
MATYPE	2	As described above.
UPL	2	User Packet Length in bits, in the range [0,65535].
DFL	2	Data Field Length in bits, in the range [0,58112].
SYNC	1	A copy of the User Packet SYNC byte. In the case of GCS, SYNC=0x00-0xB8 is reserved for transport layer protocol signalling and shall be set according to [1], SYNC=0xB9-0xFF user private.
SYNCD	2	The distance in bits from the beginning of the DATA FIELD to the beginning of the first transmitted UP which starts in the data field. SYNCD=0 _D means that the first UP is aligned to the beginning of the Data Field. SYNCD = 65535 _D means that no UP starts in the DATA FIELD; for GCS, SYNCD is reserved for future use and shall be set to 0 _D unless otherwise defined.
CRC-8 MODE	1	The XOR of the CRC-8 (1-byte) field with the MODE field (1-byte). CRC-8 is the error detection code applied to the first 9 bytes of the BBHeader (see annex E). MODE (8 bits) shall be: <ul style="list-style-type: none"> • 0_D Normal Mode. • 1_D High Efficiency Mode. • Other values: reserved for future use.

5.1.7 Mode adaptation sub-system output stream formats

This clause describes the mode adaptation processing and fragmentation for the various modes and input stream formats, as well as illustrating the output stream format.

Normal Mode, GFPS and TS

See clause 5.1.6 for BBHeader signalling.

For Transport Stream, O-UPL=188x8 bits, and the first byte shall be a SYNC byte (47_{HEX}). UPL (the transmitted User Packet Length) shall initially be set equal to O-UPL.

The mode adaptation unit shall perform the following sequence of operations (see figure 5):

- Optional input stream synchronization (see clause 5.1.3); UPL increased by 16_D or 24_D bits according to ISSY field length; ISSY field appended after each UP. For TS, either the short or long format of ISSY may be used; for GFPS, only the short format may be used.
- If a SYNC byte is the first byte of the UP, it shall be removed, and stored in the SYNC field of the BBHeader, and UPL shall be decreased by 8_D. Otherwise SYNC in the BBHeader shall be set to 0 and UPL shall remain unmodified.
- For TS only, optional Null Packet Deletion (see clause 5.1.4); DNP computation and storage after the next transmitted UP; UPL increased by 8_D.
- CRC-8 computation at UP level (see clause 5.1.5); CRC-8 storage after the UP; UPL increased by 8_D.
- SYNCD computation (pointing at the first bit of the first transmitted UP which starts in the Data Field) and storage in BBHeader. The bits of the transmitted UP start with the CRC-8 of the previous UP, if used, followed by the original UP itself, and finish with the ISSY and DNP fields, if used. Hence SYNCD points to the first bit of the CRC-8 of the previous UP.
- For GFPS: UPL storage in BBHeader.

NOTE 1: O-UPL in the modulator may be derived by static setting (GFPS only) or un-specified automatic signalling.

NOTE 2: Normal Mode is compatible with DVB-S2 BBFrame Mode Adaptation [i.3]. SYNCD=0 means that the UP is aligned to the start of the Data Field and when present, the CRC-8 (belonging to the last UP of the previous BBFrame) will be replaced in the receiver by the SYNC byte or discarded.

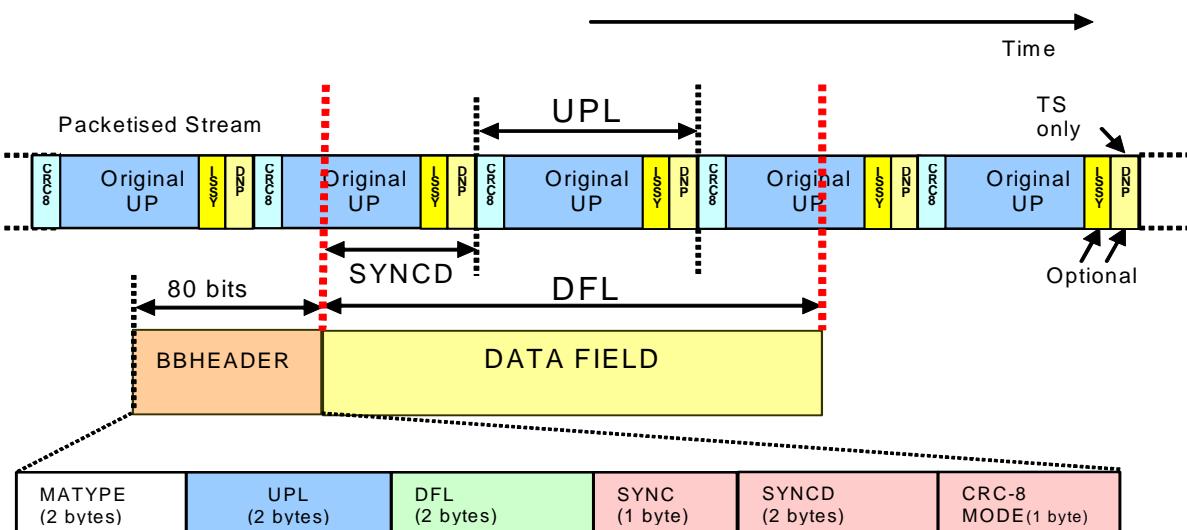

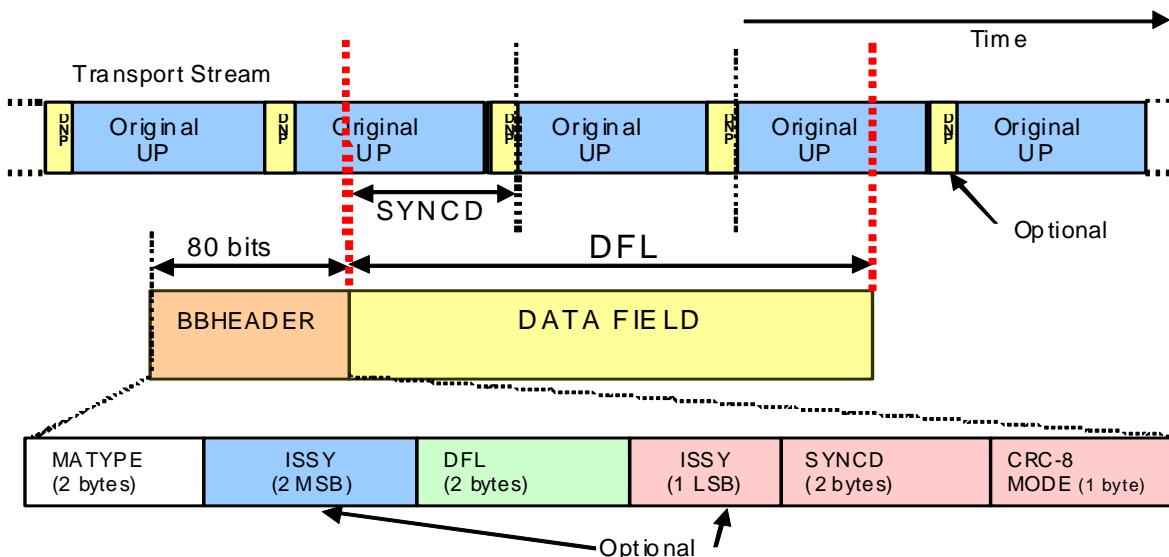

Figure 5: Stream format at the output of the Mode Adapter, Normal Mode, GFPS and TS

High Efficiency Mode, Transport Streams

For **Transport Streams**, the receiver knows a-priori the SYNC byte configuration and O-UPL=188x8 bits, therefore UPL and SYNC fields in the BBHeader shall be re-used to transmit the ISSY field. The Mode Adaptation unit shall perform the following sequence of operations (see figure 6):

- Optional input stream synchronization (see clause 5.1.3) relevant to the first complete transmitted UP of the data field; ISSY field inserted in the UPL and SYNC fields of the BBHeader.
- Sync-byte removed, but not stored in the SYNC field of the BBHeader.
- Optional Null Packet Deletion (see clause 5.1.4); DNP computation and storage after the next transmitted UP.
- CRC-8 at UP level shall not be computed nor inserted.
- SYNCD computation (pointing at the first bit of the first transmitted UP which starts in the Data Field) and storage in BBHeader. The bits of the transmitted UP start with the original UP itself after removal of the SYNC byte, and finish with the DNP field, if used. Hence SYNCD points to the first bit of the original UP following the SYNC byte.
- UPL not computed nor transmitted in the BBHeader.

**Figure 6: Stream format at the output of the Mode Adapter, High Efficiency Mode for TS,
(no CRC-8 computed for UPs, optional single ISSY inserted
in the BBHeader, UPL not transmitted)**

Normal Mode, GCS and GSE

See clause 5.1.6 for BBHeader signalling. For GCS the input stream shall have no structure, or the structure shall not be known by the modulator. For GSE the first GSE packet shall always be aligned to the data field (no GSE fragmentation allowed).

For both GCS and GSE the Mode Adaptation unit shall perform the following sequence of operations (see figure 6):

- Set UPL=0_D; set SYNC=0x00-0xB8 is reserved for transport layer protocol signalling and should be set according to Reference [1], SYNC=0xB9-0xFF user private; SYNCD is reserved for future use and shall be set to 0_D when not otherwise defined.
- Null Packed Deletion (see clause 5.1.4) and CRC-8 computation for Data Field (see clause 5.1.5) shall not be performed.

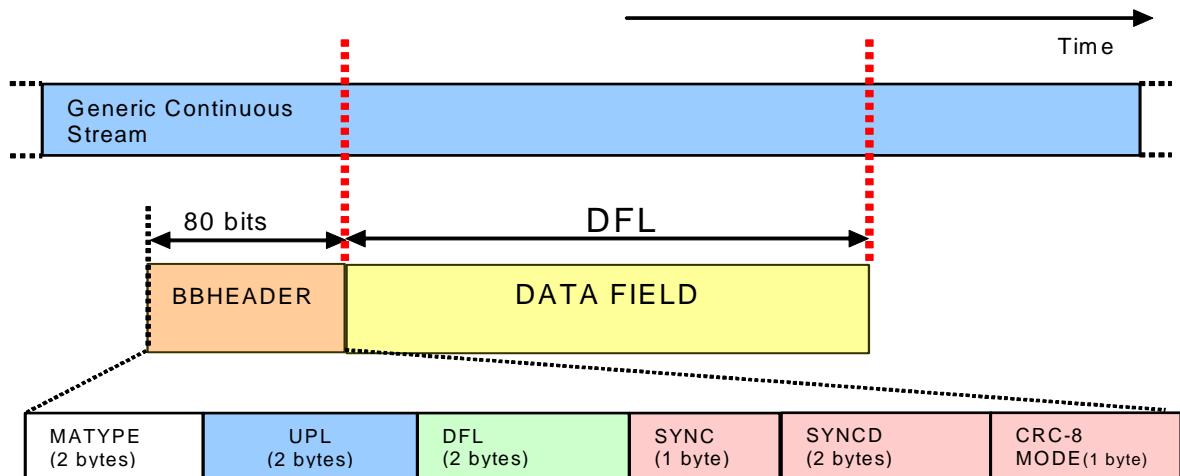

Figure 7: Stream format at the output of the Mode Adapter, Normal Mode (GSE & GCS)

High Efficiency Mode, GSE

GSE variable length or constant length UPs may be transmitted in HEM. If GSE packet fragmentation is used, SYNC shall be computed. If the GSE packets are not fragmented, the first packet shall be aligned to the Data Field and thus SYNC shall always be set to 0_D. The receiver may derive the length of the UPs from [i.2], therefore UPL transmission in BBHeader is not performed. As per TS, the optional ISSY field is transmitted in the BBHeader.

The Mode Adaptation unit shall perform the following sequence of operations (see figure 7):

- Optional input stream synchronization (see clause 5.1.3) relevant to the first transmitted UP which starts in the data field; ISSY field inserted in the UPL and SYNC fields of the BBHeader.
- Null Packet Deletion and CRC-8 at UP level shall not be computed nor inserted.
- SYNC computation (pointing at the first bit of the first transmitted UP which starts in the Data Field) and storage in BBHeader. The transmitted UP corresponds exactly to the original UP itself. Hence SYNC points to the first bit of the original UP.
- UPL not computed nor transmitted.

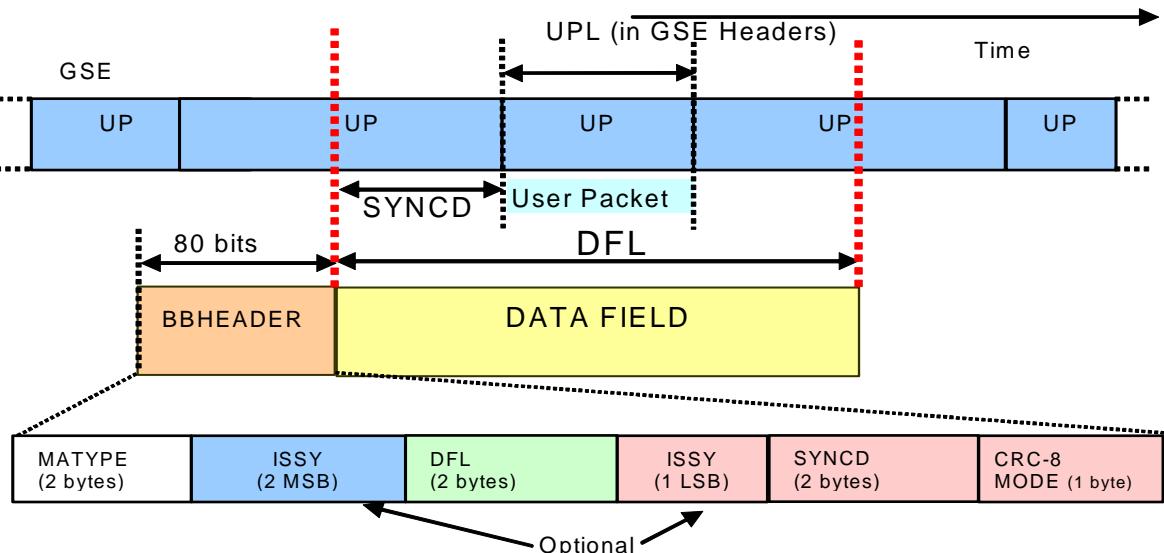

Figure 8: Stream format at the output of the Mode Adapter, High Efficiency Mode for GSE, (no CRC-8 computed for UPs, optional single ISSY inserted in the BBHeader, UPL not transmitted)

High Efficiency Mode, GFPS and GCS

These modes are not defined (except for the case of TS, as described above).

5.2 Stream adaptation

Stream adaptation (see figures 2(a) to 2(c)) provides:

- a) scheduling (see clause 5.2.1);
- b) padding (see clause 5.2.2) to complete a constant length (K_{bch} bits) BBFrame;
- c) scrambling (see clause 5.2.3) for energy dispersal.

The input stream to the stream adaptation module shall be a BBHeader followed by a DATA FIELD. The output stream shall be a BBFrame, as shown in figure 9.

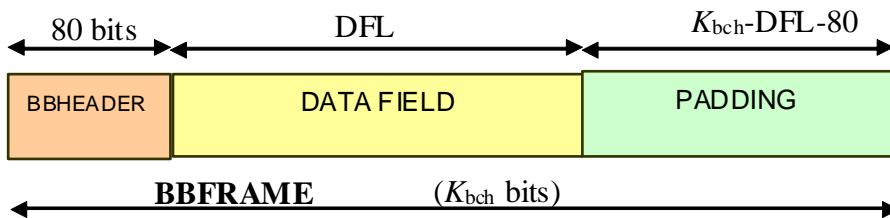

Figure 9: BBFrame format at the output of the stream adapter

5.2.1 Scheduler

In order to generate the required L1-part2 signalling information, the scheduler shall decide together with the Data Slice builder which Data Slices of the final C2 System will carry data belonging to which PLPs, as shown in figures 2(a) to 2(c). Although this operation has no effect on the data stream itself at this stage, the scheduler shall already define the composition of the Data Slice and C2 Frame structure, as described in clause 7.

5.2.2 Padding

K_{bch} depends on the FEC rate, as reported in tables 3(a) and 3(b). Padding may be applied in circumstances when the user data available for transmission is not sufficient to completely fill a BBFrame, or when an integer number of UPs has to be allocated in a BBFrame.

$(K_{\text{bch}}-\text{DFL}-80)$ zero bits shall be appended after the DATA FIELD. The resulting BBFrame shall have a constant length of K_{bch} bits.

5.2.3 BB scrambling

The complete BBFrame shall be randomized. The randomization sequence shall be synchronous with the BBFrame, starting from the MSB and ending after K_{bch} bits.

The scrambling sequence shall be generated by the feed-back shift register of figure 10. The polynomial for the Pseudo Random Binary Sequence (PRBS) generator shall be:

$$1 + X^{14} + X^{15}$$

Loading of the sequence (100101010000000) into the PRBS register, as indicated in figure 10, shall be initiated at the start of every BBFrame.

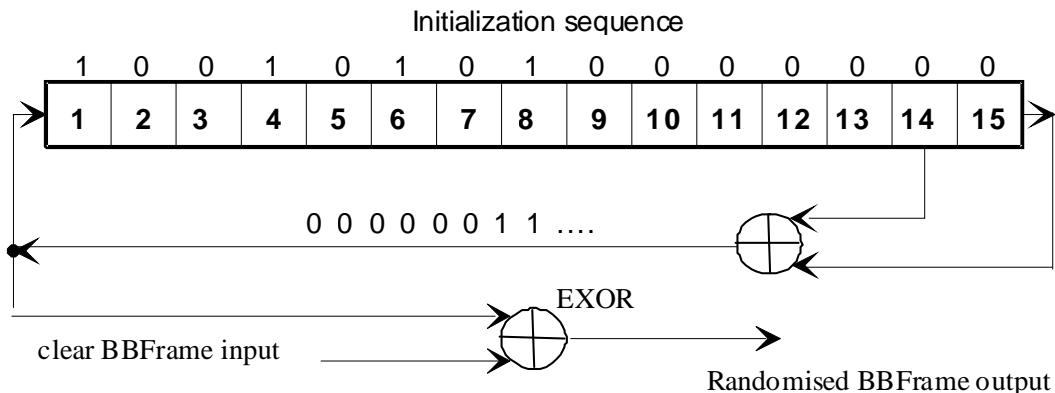

Figure 10: Possible implementation of the PRBS encoder

6 Bit-interleaved coding and modulation

6.1 FEC encoding

This sub-system shall perform outer coding (BCH), inner coding (LDPC) and bit interleaving. The input stream shall be composed of BBFrames and the output stream of FECFrames.

Each BBFrames (K_{bch} bits) shall be processed by the FEC coding sub-system, to generate a FECFrame (N_{ldpc} bits). The parity check bits (BCHFEC) of the systematic BCH outer code shall be appended after the BBFrame, and the parity check bits (LDPCFEC) of the inner LDPC encoder shall be appended after the BCHFEC field, as shown in figure 11.

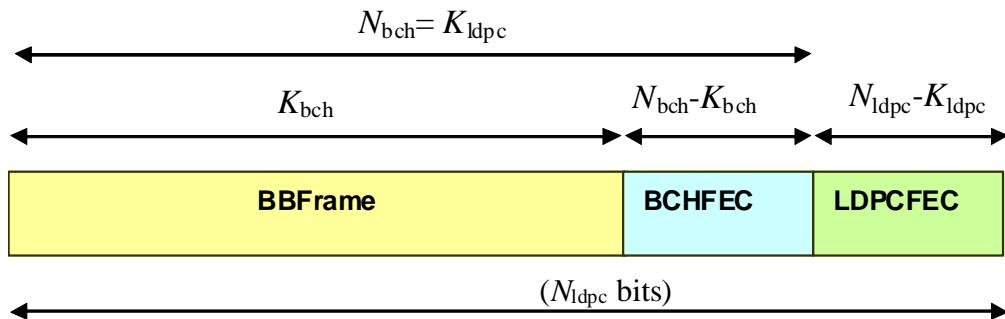

Figure 11: Format of data before bit interleaving
 $(N_{\text{ldpc}} = 64\ 800 \text{ bits for normal FECFrame}, N_{\text{ldpc}} = 16\ 200 \text{ bits for short FECFrame})$

Table 3(a) defines the FEC coding parameters for the normal FECFrame ($N_{\text{ldpc}} = 64\ 800$ bits) and table 3(b) for the short FECFrame ($N_{\text{ldpc}} = 16\ 200$ bits).

Table 3(a): Coding parameters (for normal FECFrame $N_{ldpc} = 64\ 800$)

LDPC Code	BCH Uncoded Block K_{bch}	BCH coded block N_{bch} LDPC Uncoded Block K_{ldpc}	BCH t-error correction	$N_{bch}-K_{bch}$	LDPC Coded Block N_{ldpc}
2/3	43 040	43 200	10	160	64 800
3/4	48 408	48 600	12	192	64 800
4/5	51 648	51 840	12	192	64 800
5/6	53 840	54 000	10	160	64 800
9/10	58 192	58 320	8	128	64 800

Table 3(b): Coding parameters (for short FECFrame $N_{ldpc} = 16\ 200$)

LDPC Code Identifier	BCH Uncoded Block K_{bch}	BCH coded block N_{bch} LDPC Uncoded Block K_{ldpc}	BCH t-error correction	$N_{bch}-K_{bch}$	Effective LDPC Rate $K_{ldpc}/16\ 200$	LDPC Coded Block N_{ldpc}
1/2 (see note)	7 032	7 200	12	168	4/9	16 200
2/3	10 632	10 800	12	168	2/3	16 200
3/4	11 712	11 880	12	168	11/15	16 200
4/5	12 432	12 600	12	168	7/9	16 200
5/6	13 152	13 320	12	168	37/45	16 200
8/9	14 232	14 400	12	168	8/9	16 200

NOTE: This code rate is only used for protection of L1 pre-signalling and not for data.

NOTE: For $N_{ldpc} = 64\ 800$ and for $N_{ldpc} = 16\ 200$ the LDPC code rate is given by K_{ldpc} / N_{ldpc} . In table 3(a) the LDPC code rates for $N_{ldpc} = 64\ 800$ are given by the values in the 'LDPC Code' column. In table 3(b) the LDPC code rates for $N_{ldpc} = 16\ 200$ are given by the values in the 'Effective LDPC rate' column, i.e. for $N_{ldpc} = 16\ 200$ the 'LDPC Code identifier' is *not* equivalent to the LDPC code rate.

6.1.1 Outer encoding (BCH)

A t-error correcting BCH (N_{bch} , K_{bch}) code shall be applied to each BBFrame to generate an error protected packet. The BCH code parameters for $N_{ldpc} = 64\ 800$ are given in table 3(a) and for $N_{ldpc} = 16\ 200$ in table 3(b).

The generator polynomial of the t error correcting BCH encoder is obtained by multiplying the first t polynomials in table 4(a) for $N_{ldpc} = 64\ 800$ and in table 4(b) for $N_{ldpc} = 16\ 200$.

Table 4(a): BCH polynomials (for normal FECFrame $N_{ldpc} = 64\ 800$)

$g_1(x)$	$1+x^2+x^3+x^5+x^{16}$
$g_2(x)$	$1+x+x^4+x^5+x^6+x^8+x^{16}$
$g_3(x)$	$1+x^2+x^3+x^4+x^5+x^7+x^8+x^9+x^{10}+x^{11}+x^{16}$
$g_4(x)$	$1+x^2+x^4+x^6+x^9+x^{11}+x^{12}+x^{14}+x^{16}$
$g_5(x)$	$1+x+x^2+x^3+x^5+x^8+x^9+x^{10}+x^{11}+x^{12}+x^{16}$
$g_6(x)$	$1+x^2+x^4+x^5+x^7+x^8+x^9+x^{10}+x^{12}+x^{13}+x^{14}+x^{15}+x^{16}$
$g_7(x)$	$1+x^2+x^5+x^6+x^8+x^9+x^{10}+x^{11}+x^{13}+x^{15}+x^{16}$
$g_8(x)$	$1+x+x^2+x^5+x^6+x^8+x^9+x^{12}+x^{13}+x^{14}+x^{16}$
$g_9(x)$	$1+x^5+x^7+x^9+x^{10}+x^{11}+x^{16}$
$g_{10}(x)$	$1+x+x^2+x^5+x^7+x^8+x^{10}+x^{12}+x^{13}+x^{14}+x^{16}$
$g_{11}(x)$	$1+x^2+x^3+x^5+x^9+x^{11}+x^{12}+x^{13}+x^{16}$
$g_{12}(x)$	$1+x+x^5+x^6+x^7+x^9+x^{11}+x^{12}+x^{16}$

Table 4(b): BCH polynomials (for short FECFrame $N_{ldpc} = 16\ 200$)

$g_1(x)$	$1+x+x^3+x^5+x^{14}$
$g_2(x)$	$1+x^6+x^8+x^{11}+x^{14}$
$g_3(x)$	$1+x+x^2+x^6+x^9+x^{10}+x^{14}$
$g_4(x)$	$1+x^4+x^7+x^8+x^{10}+x^{12}+x^{14}$
$g_5(x)$	$1+x^2+x^4+x^6+x^8+x^9+x^{11}+x^{13}+x^{14}$
$g_6(x)$	$1+x^3+x^7+x^8+x^9+x^{13}+x^{14}$
$g_7(x)$	$1+x^2+x^5+x^6+x^7+x^{10}+x^{11}+x^{13}+x^{14}$
$g_8(x)$	$1+x^5+x^8+x^9+x^{10}+x^{11}+x^{14}$
$g_9(x)$	$1+x+x^2+x^3+x^9+x^{10}+x^{14}$
$g_{10}(x)$	$1+x^3+x^6+x^9+x^{11}+x^{12}+x^{14}$
$g_{11}(x)$	$1+x^4+x^{11}+x^{12}+x^{14}$
$g_{12}(x)$	$1+x+x^2+x^3+x^5+x^6+x^7+x^8+x^{10}+x^{13}+x^{14}$

BCH encoding of information bits $M = (m_{K_{bch}-1}, m_{K_{bch}-2}, \dots, m_1, m_0)$ onto a codeword is achieved as follows:

- Multiply the message polynomial $m(x) = m_{K_{bch}-1}x^{k_{bch}-1} + m_{K_{bch}-2}x^{k_{bch}-2} + \dots + m_1x + m_0$ by $x^{N_{bch}-K_{bch}}$.
- Divide $x^{N_{bch}-K_{bch}} m(x)$ by $g(x)$, the generator polynomial. Let $d(x) = d_{N_{bch}-K_{bch}-1}x^{N_{bch}-K_{bch}-1} + \dots + d_1x + d_0$ be the remainder.
- Construct the output codeword I , which forms the information word I for the LDPC coding, as follows:

$$I = (i_0, i_1, \dots, i_{N_{bch}-1}) = (m_{K_{bch}-1}, m_{K_{bch}-2}, \dots, m_1, m_0, d_{N_{bch}-K_{bch}-1}, d_{N_{bch}-K_{bch}-2}, \dots, d_1, d_0)$$

NOTE: The equivalent codeword polynomial is $c(x) = x^{N_{bch}-K_{bch}} m(x) + d(x)$.

6.1.2 Inner encoding (LDPC)

The LDPC encoder treats the output of the outer encoding, $I = (i_0, i_1, \dots, i_{K_{ldpc}-1})$, as an information block of size $K_{ldpc} = N_{BCH}$, and systematically encodes it onto a codeword Λ of size N_{ldpc} , where:

$$\Lambda = (\lambda_0, \lambda_1, \lambda_2, \dots, \lambda_{N_{LDPC}}) = (i_0, i_1, \dots, i_{K_{ldpc}-1}, p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1}).$$

The LDPC code parameters (N_{ldpc}, K_{ldpc}) are given in tables 3(a) and 3(b).

6.1.2.1 Inner coding for normal FECFrame

The task of the encoder is to determine $N_{ldpc} - K_{ldpc}$ parity bits $(p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1})$ for every block of k_{ldpc} information bits, $(i_0, i_1, \dots, i_{K_{ldpc}-1})$. The procedure is as follows:

- Initialize $p_0 = p_1 = p_2 = \dots = p_{N_{ldpc}-K_{ldpc}-1} = 0$
- Accumulate the first information bit, i_0 , at parity bit addresses specified in the first row of tables A.1 through A.5. For example, for rate 2/3 (A.1), (all additions are in GF(2)):

$$p_{317} = p_{317} \oplus i_0$$

$$p_{6700} = p_{6700} \oplus i_0$$

$$p_{2255} = p_{2255} \oplus i_0$$

$$p_{9101} = p_{9101} \oplus i_0$$

$$\begin{array}{ll}
 p_{2324} = p_{2324} \oplus i_0 & p_{10057} = p_{10057} \oplus i_0 \\
 p_{2723} = p_{2723} \oplus i_0 & p_{12739} = p_{12739} \oplus i_0 \\
 p_{3538} = p_{3538} \oplus i_0 & p_{17407} = p_{17407} \oplus i_0 \\
 p_{3576} = p_{3576} \oplus i_0 & p_{21039} = p_{21039} \oplus i_0 \\
 p_{6194} = p_{6194} \oplus i_0 &
 \end{array}$$

- For the next 359 information bits, $i_m, m=1, 2, \dots, 359$ accumulate i_m at parity bit addresses $\{x + m \bmod 360 \times Q_{ldpc}\} \bmod (N_{ldpc} - K_{ldpc})$ where x denotes the address of the parity bit accumulator corresponding to the first bit i_0 , and Q_{ldpc} is a code rate dependent constant specified in table 5(a). Continuing with the example, $Q_{ldpc} = 60$ for rate 2/3. So for example for information bit i_1 , the following operations are performed:

$$\begin{array}{ll}
 p_{377} = p_{377} \oplus i_1 & p_{6760} = p_{6760} \oplus i_1 \\
 p_{2315} = p_{2315} \oplus i_1 & p_{9161} = p_{9161} \oplus i_1 \\
 p_{2384} = p_{2384} \oplus i_1 & p_{10117} = p_{10117} \oplus i_1 \\
 p_{2783} = p_{2783} \oplus i_1 & p_{12799} = p_{12799} \oplus i_1 \\
 p_{3598} = p_{3598} \oplus i_1 & p_{17467} = p_{17467} \oplus i_1 \\
 p_{3636} = p_{3636} \oplus i_1 & p_{21099} = p_{21099} \oplus i_1 \\
 p_{6254} = p_{6254} \oplus i_1 &
 \end{array}$$

- For the 361st information bit i_{360} , the addresses of the parity bit accumulators are given in the second row of the tables A.1 through A.5. In a similar manner the addresses of the parity bit accumulators for the following 359 information bits $i_m, m = 361, 362, \dots, 719$ are obtained using the formula $\{x + (m \bmod 360) \times Q_{ldpc}\} \bmod (N_{ldpc} - K_{ldpc})$ where x denotes the address of the parity bit accumulator corresponding to the information bit i_{360} , i.e. the entries in the second row of tables A.1 through A.5.
- In a similar manner, for every group of 360 new information bits, a new row from tables A.1 through A.5 are used to find the addresses of the parity bit accumulators.

After all of the information bits are exhausted, the final parity bits are obtained as follows:

- Sequentially perform the following operations starting with $i = 1$.

$$p_i = p_i \oplus p_{i-1}, \quad i = 1, 2, \dots, N_{ldpc} - K_{ldpc} - 1$$

- Final content of p_i , $i = 0, 1, \dots, N_{ldpc} - K_{ldpc} - 1$ is equal to the parity bit p_i .

Table 5(a): Q_{ldpc} values for normal frames

Code Rate	Q_{ldpc}
2/3	60
3/4	45
4/5	36
5/6	30
9/10	18

6.1.2.2 Inner coding for short FECFrame

K_{ldpc} BCH encoded bits shall be systematically encoded to generate N_{ldpc} bits as described in clause 6.1.2.1, replacing table 5(a) with table 5(b) and the tables of annex A with the tables of annex B.

Table 5(b): Q_{ldpc} values for short frames

Code Rate	Q_{ldpc}
1/2	25
2/3	15
3/4	12
4/5	10
5/6	8
8/9	5

6.1.3 Bit Interleaver

The output A of the LDPC encoder shall be bit interleaved, which consists of parity interleaving followed by column-twist interleaving. The parity interleaver output is denoted by U and the column-twist interleaver output by V .

In the parity interleaving part, parity bits are interleaved by:

$$u_i = \lambda_i \text{ for } 0 \leq i < K_{ldpc} \text{ (information bits are not interleaved);}$$

$$u_{K_{ldpc}+360t+s} = \lambda_{K_{ldpc}+Q_{ldpc}\cdot s+t} \text{ for } 0 \leq s < 360, 0 \leq t < Q_{ldpc};$$

where Q_{ldpc} is defined in tables 5(a) and 5(b).

The configuration of the column-twist interleaving for each modulation format is specified in table 6.

Table 6: Bit Interleaver structure

Modulation	Rows N_r		Columns N_c
	$N_{ldpc} = 64\ 800$	$N_{ldpc} = 16\ 200$	
16QAM	8 100	2 025	8
64QAM	5 400	1 350	12
256QAM	4 050	-	16
	-	2 025	8
1024QAM	3 240	810	20
4096QAM	5 400	-	12
	-	675	24

In the column-twist interleaving part, the data bits u_i from the parity interleaver are serially written into the column-twist interleaver column-wise, and serially read out row-wise (the MSB of BBHeader is read out first) as shown in figure 12, where the write start position of each column is twisted by t_c according to table 7. This interleaver is described by the following:

- The input bit u_i with index i , for $0 \leq i < N_{ldpc}$, is written to column c_p , row r_i of the interleaver, where:

$$c_i = i \text{ div } N_r$$

$$r_i = i + t_{c_i} \text{ mod } N_r$$

- The output bit v_j with index j , for $0 \leq j < n_{ldpc}$, is read from row r_j , column c_j , where:

$$r_j = j \text{ div } N_c$$

$$c_j = j \text{ mod } N_c$$

- So for 64QAM and $N_{LDPC} = 64\ 800$, the output bit order of column twist interleaving would be:

$$(v_0, v_1, v_2, \dots, v_{64799}) = (u_0, u_{5400}, u_{16198}, \dots, u_{53992}, u_{59231}, u_{64790}).$$

A longer list of the indices on the right hand side, illustrating all 12 columns, is: 0, 5 400, 16 198, 21 598, 26 997, 32 396, 37 796, 43 195, 48 595, 53 993, 59 392, 64 791, 5 399, 10 799, 16 197, 21 597, 26 996, 32 395, 37 795, 43 194, 48 594, 53 992, 59 391, 64 790.

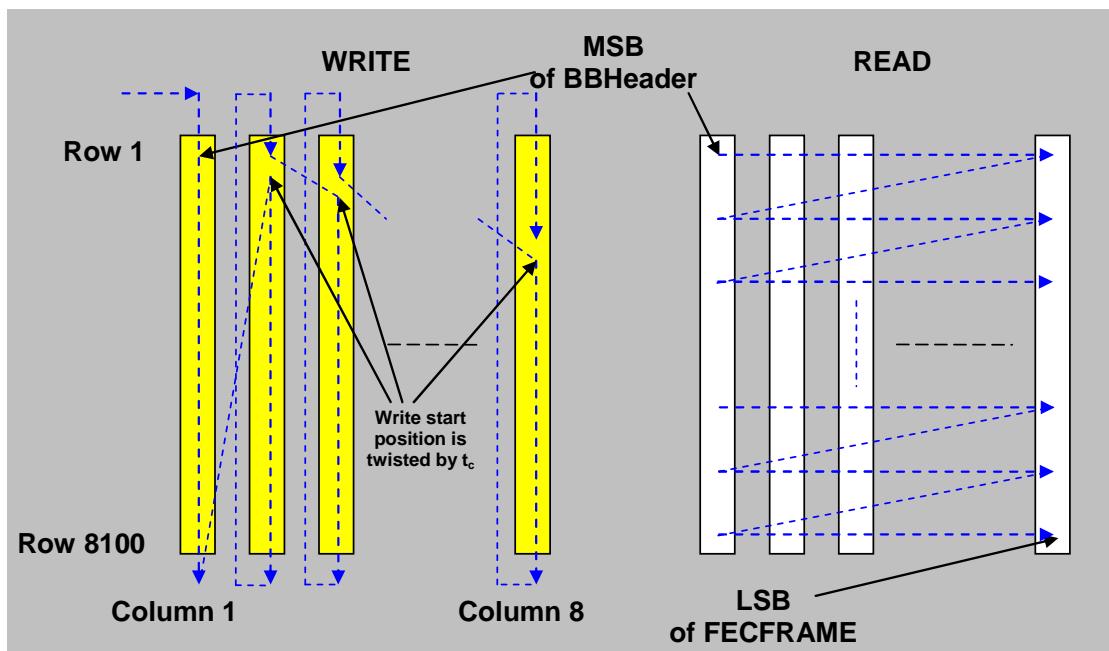

Figure 12: Bit interleaving scheme for normal FECFrame length and 16QAM

	24	16 200												

6.2 Mapping bits onto constellations

Each FECFrame (which is a sequence of 64 800 bits for normal FECFrame, or 16 200 bits for short FECFrame), shall be mapped to a coded and modulated FEC block by first demultiplexing the input bits into parallel cell words and then mapping these cell words into constellation values. The number of output Data Cells and the effective number of bits per cell η_{MOD} is defined by table 8. Demultiplexing is performed according to clause 6.2.1 and constellation mapping is performed according to clause 6.2.2.

Table 8: Parameters for bit-mapping into constellations

LDPC block length (N_{ldpc})	Modulation mode	η_{MOD}	Number of output Data Cells
64 800	4096QAM	12	5 400
	1024QAM	10	6 480
	256QAM	8	8 100
	64QAM	6	10 800
	16QAM	4	16 200
16 200	4096QAM	12	1 350
	1024QAM	10	1 620
	256QAM	8	2 025
	64QAM	6	2 700
	16QAM	4	4 050
	QPSK	2	8 100

6.2.1 Bit to cell word demultiplexer

The bit-stream v_i from the bit interleaver is demultiplexed into $N_{substreams}$ sub-streams, as shown in figure 13. The value of $N_{substreams}$ is defined in table 9.

Table 9: Number of sub-streams in demultiplexer

Modulation	N_{ldpc}	Number of sub-streams, $N_{substreams}$
QPSK	Any	2
16QAM	Any	8
64QAM	Any	12
256QAM	64 800	16
	16 200	8
1024QAM	Any	20
4096QAM	64 800	12
	16 200	24

The demultiplexing is defined as a mapping of the bit-interleaved input bits, v_{di} onto the output bits $b_{e,do}$, where:

- $do = di \text{ div } N_{substreams}$;
- e is the demultiplexed bit sub stream number ($0 \leq e < N_{substreams}$), which depends on di as defined in table 10;
- v_{di} is the input to the demultiplexer;
- di is the input bit number;
- $b_{e,do}$ is the output from the demultiplexer;
- do is the bit number of a given stream at the output of the demultiplexer.

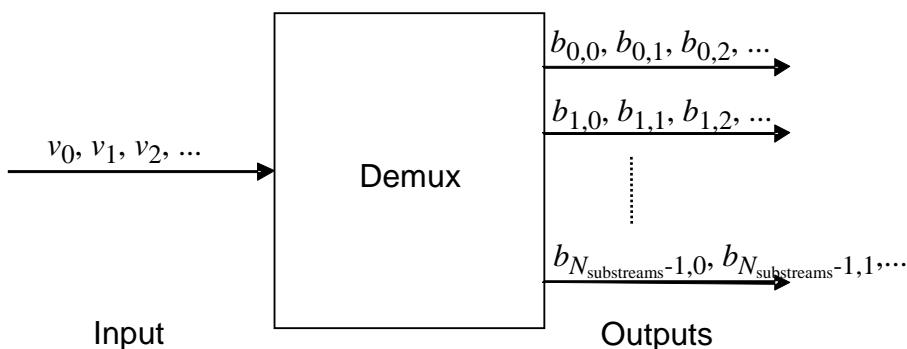

Figure 13: Demultiplexing of bits into sub-streams

		6	17	13	20	1	3	9	2	7	8	12	0								

Except for 256QAM with $N_{ldpc} = 16\ 200$ and 4096QAM with $N_{ldpc} = 64\ 800$, the words of width $N_{substreams}$ are split into two cell words of width $\eta_{MOD} = N_{substreams}/2$ at the output of the demultiplexer. The first $\eta_{mod} = N_{substreams}/2$ bits $[b_{0,do}..b_{N_{substreams}/2-1,do}]$ form the first of a pair of output cell words $[y_{0,2do}..y_{\eta_{MOD}-1,2do}]$ and the remaining output bits $[b_{N_{substreams}/2, do}..b_{N_{substreams}-1,do}]$ form the second output cell word $[y_{0,2do+1}..y_{\eta_{MOD}-1,2do+1}]$ fed to the constellation mapper.

In the case of 256QAM with $N_{ldpc} = 16\ 200$ and 4096QAM with $N_{ldpc} = 64\ 800$, the words of width 8 from the demultiplexer form the output cell words and are fed directly to the constellation mapper, so:

$$[y_{0,do} \dots y_{\eta mod-1,do}] = [b_{0,do} \dots b_{Nsubstreams-1,do}]$$

The application of the parameters in tables 10(a) and 10(b), for the demultiplexing of the bit-stream v_i from the bit interleaver, is subordinated to the validity of a specific modulation and code rate combination, since DVB-C2 only supports a list of selected ModCod configurations, as shown in tables 11(a) and 11(b) (X indicates a valid configuration).

Table 11(a): ModCods for $N_{ldpc} = 64\ 800$

6.2.2 Cell word mapping into I/Q constellations

Each cell word ($y_{0,q} \dots y_{\eta mod-1,q}$) from the demultiplexer in clause 6.2.1 shall be modulated using either QPSK, 16QAM, 64QAM, 256QAM, 1024QAM, 4096QAM constellations to give a constellation point z_q prior to normalization.

The exact values of the real and imaginary components $\text{Re}(z_q)$ and $\text{Im}(z_q)$ for each combination of the relevant input bits $y_{e,q}$ are given in tables 12(a-m) for the various constellations:

Table 12(a): Constellation mapping for BPSK

$y_{0,q}$	1	0
$\text{Re}(z_q)$	-1	1
$\text{Im}(z_q)$	0	0

Table 12(b): Constellation mapping for real part of QPSK

$y_{0,q}$	1	0
$\text{Re}(z_q)$	-1	1

Table 12(c): Constellation mapping for imaginary part of QPSK

$y_{1,q}$	1	0
$\text{Im}(z_q)$	-1	1

Table 12(d): Constellation mapping for real part of 16QAM

The constellations, and the details of the Gray mapping applied to them, are illustrated in figures 14 and 15.

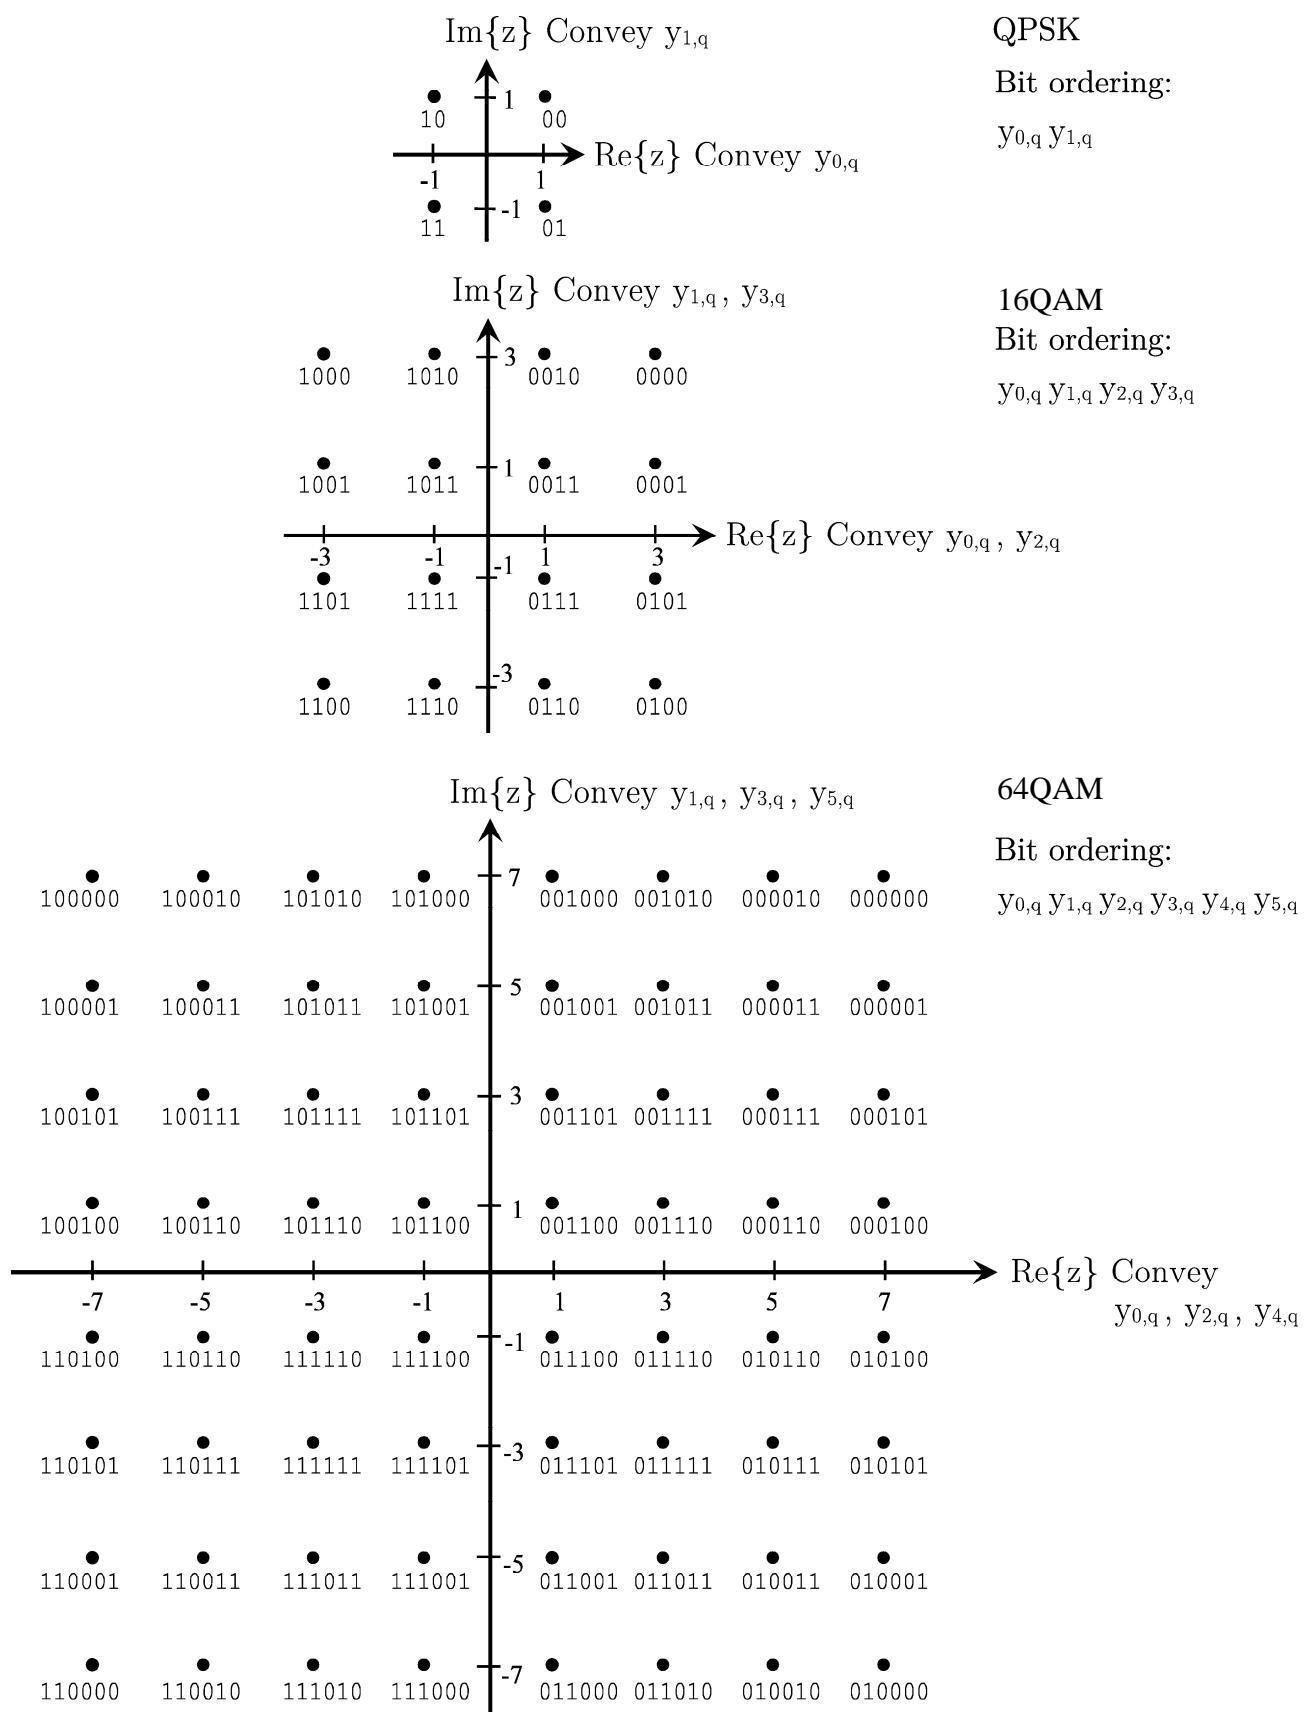

Figure 14: The QPSK, 16QAM and 64QAM mappings and the corresponding bit patterns

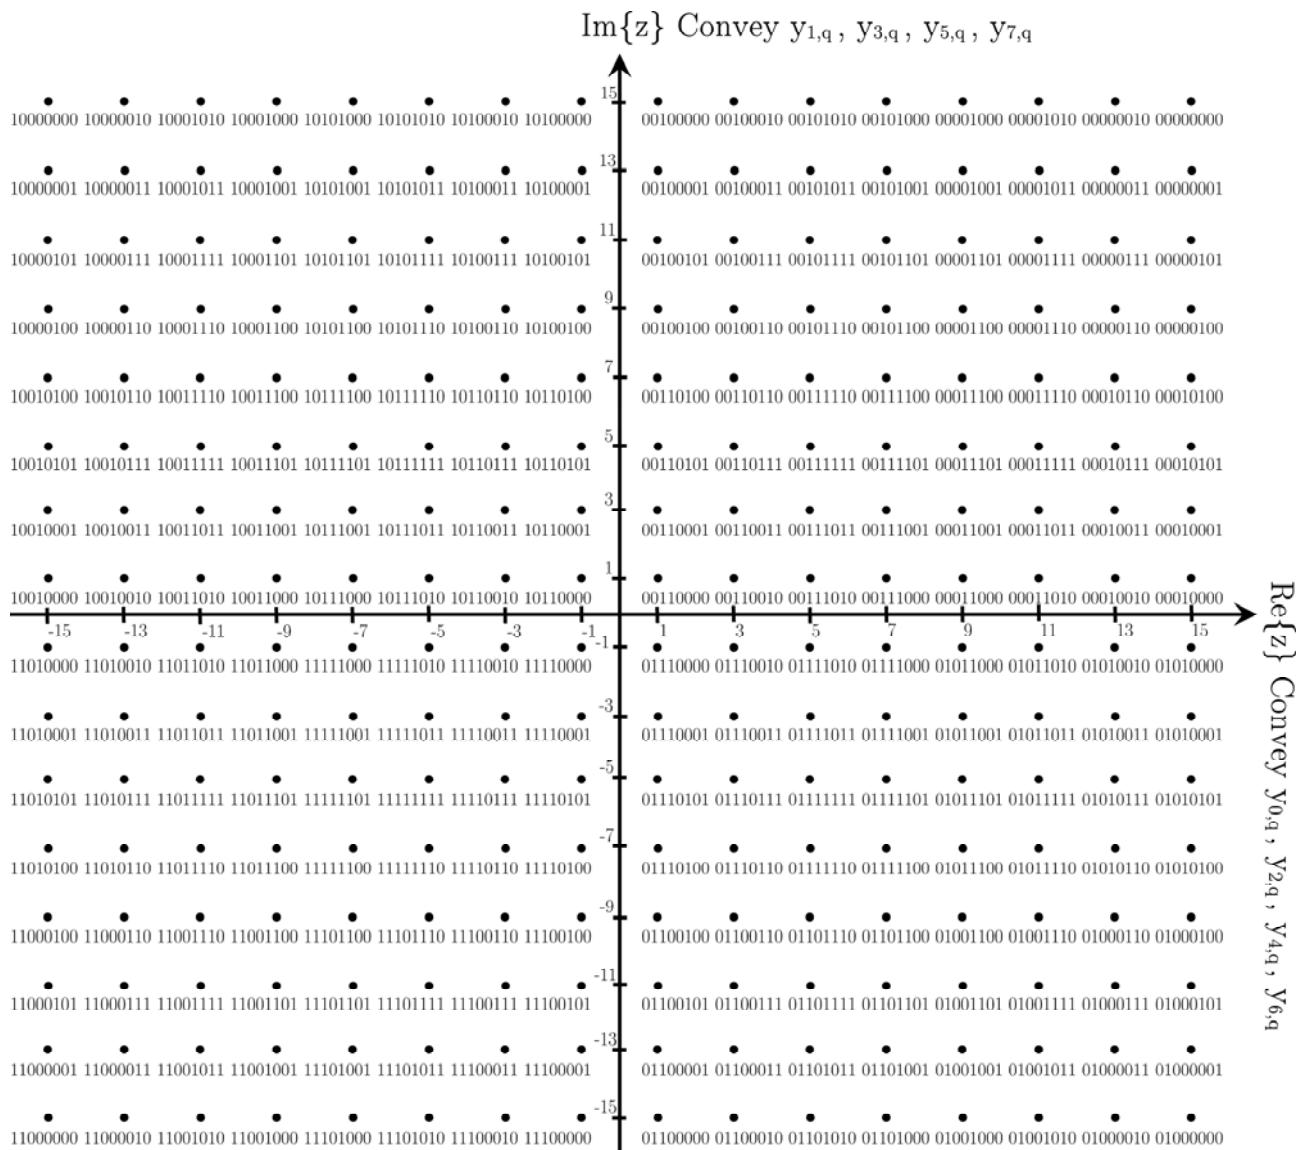

Figure 15: The 256QAM mapping and the corresponding bit pattern

Tables 12(j) and 12(k) provide the description of 1024QAM mapping and the corresponding bit pattern. Tables 12(l) and 12(m) provide the description of 4096QAM mapping and the corresponding bit pattern.

The constellation points z_q for each input cell word ($y_{0,q} \dots y_{\eta \bmod 1,q}$) are normalized according to table 13 to obtain the correct complex cell value f_q to be used.

Table 13: Normalization factors for Data Cells

Modulation	Normalization
QPSK	$f_q = \frac{z_q}{\sqrt{2}}$
16QAM	$f_q = \frac{z_q}{\sqrt{10}}$
64QAM	$f_q = \frac{z_q}{\sqrt{42}}$
256QAM	$f_q = \frac{z_q}{\sqrt{170}}$
1024QAM	$f_q = \frac{z_q}{\sqrt{682}}$
4096QAM	$f_q = \frac{z_q}{\sqrt{2730}}$

7 Data Slice Packet Generation

The complex cells of one or two FECFrame shall form a Data Slice Packet. The Data Slice Packets for Data Slice Type 1 only transmit the FECFrame data and rely on a pointer within the Level 1 Signalling Part 2 to detect their start.

The Data Slice Packets for Data Slice Type 2 carry a FECFrame header that allows for synchronization to the Data Slice Packets without any additional information. The FECFrame header also signals the Modulation and Coding parameters and the PLP_ID, which may change every Data Slice Packet.

7.1 Data Slice Packets for Data Slice Type 1

The complex cells g of Data Slice Packets transmitted in Data Slices of type 1 (DSLICE_TYPE='0') shall be formed by the $\left\lceil N_{ldpc} / \eta_{MOD} \right\rceil = N_{DP}$ complex cells of one LDPC codeword, i.e.:

$$g_q = f_q \quad q = 0, 1, \dots, N_{DP} - 1$$

The signalling for Data Slices of type 1 is done within the DVB-C2 preamble, i.e. the Layer 1 - part 2. Additional signalling is not required, as only a single PLP with fixed modulation and coding parameters per DVB-C2 frame is allowed for Data Slices Type 1.

7.2 Data Slice Packets for Data Slice Type 2

Data Slice Packets for Data Slice Type 2 shall carry an additional FECFrame Header in front of one or two FECFrames, which signals the PLP_ID, the Coding and Modulation parameters of the following XFECFrame, and the number of XFECFrames following one header. The structure of these Data Slice Packets is given in figure 16.

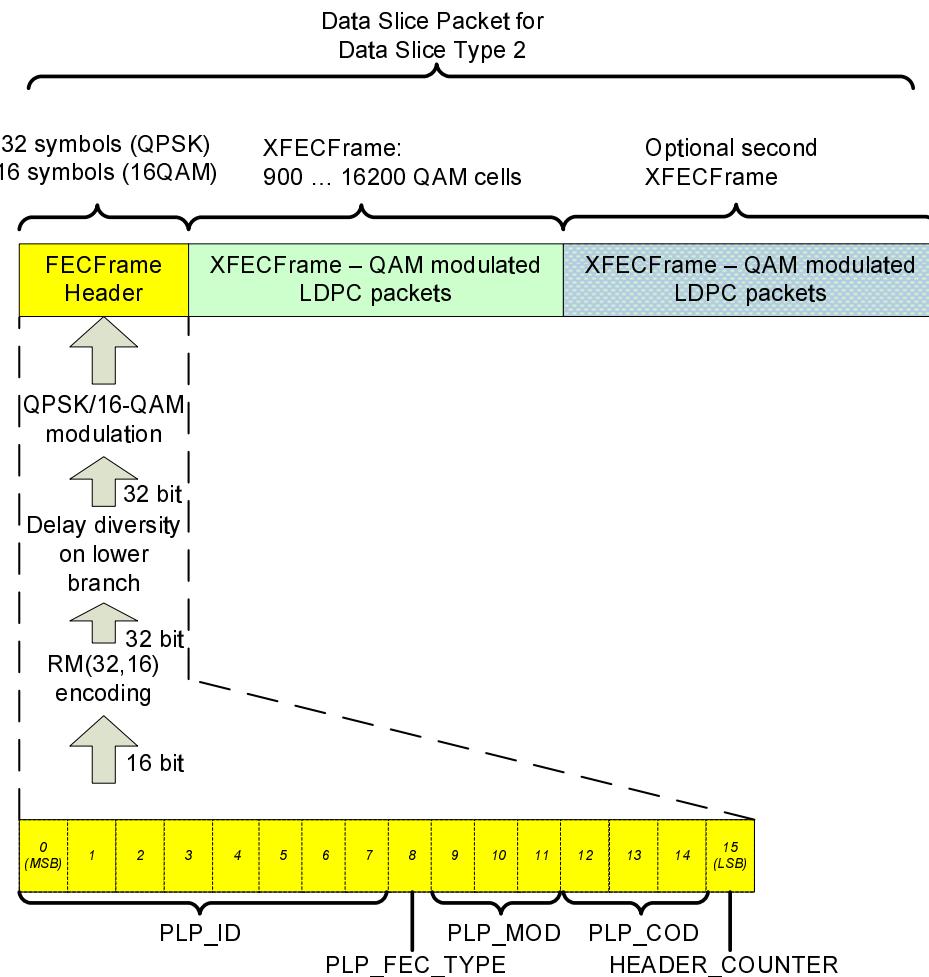

Figure 16: Data Slice Packet, consisting of FECFrame header and following XFECFrame packet

7.2.1 FECFrame header signalling data

The 16 information bits of the FECFrame header are defined as follows, in which the MSB shall always be mapped first:

PLP_ID: This 8-bit field uniquely identifies a PLP within a C2 system.

PLP_FEC_TYPE: This field shall signal the size of the following FECFrame (0 = 16 200 bits, 1 = 64 800 bits).

PLP_MOD: This 3 bit field signals the used QAM mappings according to table 14.

Table 14: PLP_MOD values for the available QAM mappings

Value	QAM mapping
000	Reserved
001	16QAM
010	64QAM
011	256QAM
100	1024QAM
101	4096QAM
110 to 111	Reserved for future use

PLP_COD: This field signals the LDPC code rate of the following FECFrame according to table 15. Please note that not all possible PLP_MOD and PLP_COD combinations are supported (see tables 11(a) and 11(b)).

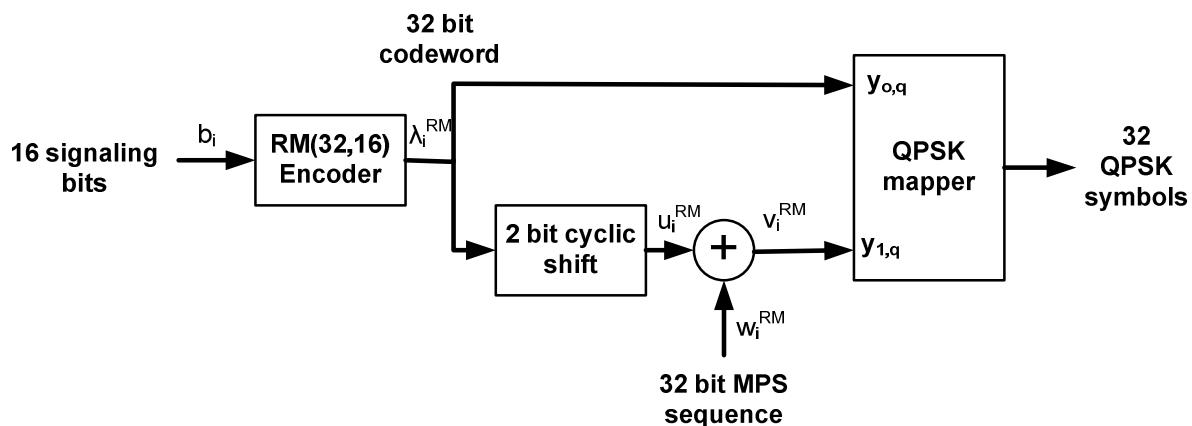

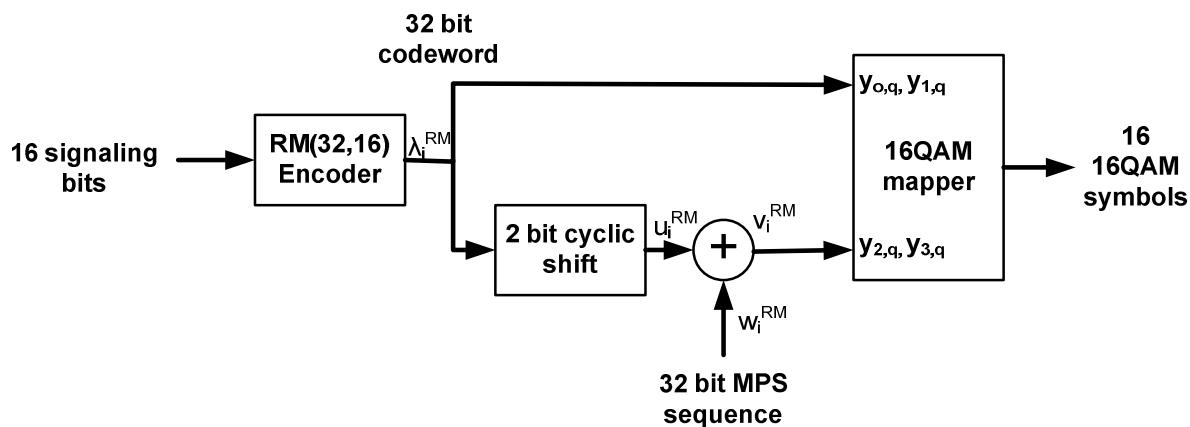

Table 15: PLP_COD values for the different code rates

Value	Code rate
000	Reserved
001	2/3
010	3/4
011	4/5
100	5/6
101	8/9 (16K LDPC code) 9/10 (64K LDPC code)
110 to 111	Reserved for future use

HEADER_COUNTER: This 1 bit field signals the number of FECFrames following this FECFrame header. '0' indicates that one FECFrame is following the FECFrame header. '1' indicates that 2 FECFrames are following the FECFrame header, while both FECFrames shall have the same PLP_ID, PLP_FEC_TYPE, PLP_MOD and PLP_COD.

7.2.2 Coding of the FECFrame header

The encoding of the FECFrame header data shall ensure a robust synchronization and decoding of the L1 signalling part 1 data. Therefore, the encoding scheme as shown in the figures 17(a) and 17(b) is applied. Initially the 16 bits of the L1 signalling part 1 are FEC encoded by a Reed-Muller (32,16) encoder. Subsequently each bit of the 32 bits Reed-Muller codeword is split to form an upper and a lower branch. The lower branch applies a cyclic shift within each Reed-Muller codeword and scrambles the resulting data using a specific PN sequence. The data is then mapped on a QPSK constellation for the robust FECFrame header or on a 16QAM constellation for the high efficiency FECFrame header.

**Figure 17(a): Robust FECFrame header****Figure 17(b): High efficiency FECFrame header**

7.2.2.1 Error Coding

The 16 information bits are FEC encoded by a Reed-Muller (32,16) code. The generator matrix for this Reed-Muller (32,16) code G is shown as follows:

Table 16(a): Definition of the Reed-Muller encoder matrix

$$G = \begin{pmatrix} 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 0 & 1 & 1 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 1 & 1 & 0 & 0 & 1 & 1 & 1 & 1 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & 0 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 & 1 & 1 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \\ 0 & 1 & 1 \end{pmatrix}$$

The 32 Reed-Muller encoded data bits vector $\lambda^{RM} = [\lambda_0^{RM}, \dots, \lambda_{31}^{RM}]$ is obtained by the matrix multiplication of the 16 bit long FECFrame signalling data vector $b = [b_0, \dots, b_{15}]$ with the generator matrix, i.e.

$$\lambda^{RM} = b \cdot G$$

All operations are applied modulo 2.

7.2.2.2 Cyclic Delay

As depicted in figures 17(a) and 17(b), the 32 Reed-Muller encoded data bits λ_i^{RM} of the lower branch shall be cyclically delayed by two values within each Reed-Muller codeword. The output of the cyclic delay block shall be:

$$u_{(i+2)\bmod 32}^{RM} = \lambda_i^{RM} \quad i = 0, 1, \dots, 31$$

7.2.2.3 Scrambling of the lower branch

The data of the lower branch shall be scrambled with the scrambling sequence:

$$w_0^{RM}, w_1^{RM}, \dots, w_{31}^{RM} = 0, 0, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 1$$

This 32 bits output sequence v_i^{RM} is obtained by applying modulo 2 operation between the cyclically shifted data u_i^{RM} and the scrambling sequence w_i^{RM} :

$$v_i^{RM} = u_i^{RM} \oplus w_i^{RM} \quad i = 0, 1, \dots, 31$$

7.2.3 Mapping onto QAM constellations

The 32 resulting bits of the upper and the 32 bits of the lower branch shall be mapped onto QAM constellations. Therefore, the same mapping means as described in clause 6.2.2 shall be used. There are 2 different FECFrame header architectures available. While the QPSK based FECFrame header is applied for cable channels with lower C/N, the 16QAM based FECFrame header provides a more efficient implementation (i.e. smaller header length) for cable channels with higher C/N values.

7.2.3.1 Robust FECFrame header

The robust FECFrame header shall be modulated using QPSK as defined in clause 6.2.2 to obtain the 32 complex cell values f_q . The 32 mapper input cell words shall be defined as:

$$[y_{0,i}, y_{1,i}] = [\lambda_i^{RM}, v_i^{RM}] \quad i = 0, 1, \dots, 31$$

This means that the bits of the upper branch are always mapped onto the real part and the bits of the lower branch are always mapped onto the imaginary part of the QAM cell.

7.2.3.2 High efficiency FECFrame header

The high efficiency FECFrame header shall be modulated using 16QAM as defined in clause 6.2.2 to obtain the 16 complex cell values f_q . The 16 mapper input cell words shall be defined as:

$$[y_{0,i}, y_{1,i}, y_{2,i}, y_{3,i}] = [\lambda_{2i}^{RM}, \lambda_{2i+1}^{RM}, v_{2i}^{RM}, v_{2i+1}^{RM}] \quad i = 0, 1, \dots, 15$$

This means that the bits of the upper branch are always modulated onto the MSB of the real and imaginary axis, while the bits of the lower branch are always modulated onto the LSB of the real and imaginary axis.

7.2.4 Mapping of the XFECFrame cells

The 32 cells for the robust FECFrame Header or the 16 cells for the high efficiency FECFrame Header shall be mapped onto the first cells of the Data Slice Packet, i.e. $g_0 = f_0$, etc.

The FECFrame header is followed by the $\left\lceil N_{ldpc} / \eta_{MOD} \right\rceil$ complex cells of one complete LDPC codeword. If HEADER_COUNT='1', one further FECFrame having the same PLP_ID, PLP_MOD and PLP_COD shall follow the first one.

7.2.5 Length of the Data Slice Packet for Data Slice Type 2

The length N_{DP} of a Data Slice Packet for Data Slice Type 2 can be calculated by means of the FECFrame Header data only. The length for packets using the robust FECFrame header shall be:

$$N_{DP} = 32 + XFECFRAME_LENGTH \cdot (1 + HEADER_COUNTER)$$

and

$$N_{DP} = 16 + XFECFRAME_LENGTH \cdot (1 + HEADER_COUNTER)$$

for the high efficiency FECFrame header.

The value XFECFRAME_LENGTH for the different values of PLP_MOD and PLP_FEC_TYPE are listed in table 16(b).

Table 16(b): Length of the FECFrame

PLP_FEC_TYPE	PLP_MOD	XFECFRAME_LENGTH
0	000	NA
	001	4 050
	010	2 700
	011	2 025
	100	1 620
	101	1 350
	110	1 158
	111	1 013
1	000	900
	001	16 200
	010	10 800
	011	8 100
	100	6 480
	101	5 400
	110	4 629
	111	4 050

7.2.6 Stuffing Data Slice Packets

Stuffing Data Slice Packets provide a mechanism to fill up Data Slices of Type 2 with Auxiliary Data. Stuffing packets shall use the PLP_MOD value '000'. Accordingly they have the minimum FECFrame length of 900QAM cells, while their total length shall be defined according to clause 7.2.4. The settings for the related stuffing FECFrame header are:

PLP_ID:	n/a	(arbitrary value)
PLP_FEC_TYPE:	1	(= 64 800 bits)
PLP_MOD:	000	(= 900QAM cells length)
PLP_COD:	n/a	(arbitrary value)
HEADER_COUNTER:	0	

Stuffing Data Slice Packets can be used in any Data Slice and any location in the C2 Frame. Both regular Data Slice Packets and stuffing Data Slice Packets overlap over different C2 Frames if their end does not coincide with the end of the C2 Frame.

If the Data Slice is discontinued in the following C2 Frame the stuffing Data Slice Packet is only transmitted partially up to the end of the C2 Frame (i.e. not completed in the following C2 Frame). In the case where the remaining part is less than the number of cells in FECFrame header and the data is discontinued the next C2 frame, the remaining cells should be transmitted. The FECFrame headers of stuffing Data Slice Packets shall match with the L1 settings of the related Data Slice.

The data content of the 900QAM stuffing Data Cells is arbitrary but shall meet the average QAM cell energy requirement.

8 Generation, coding and modulation of Layer 1 part 2 signalling

8.1 Overview

Figure 18 illustrates the C2 Frame structure and the related preamble with embedded L1 signalling part 2. The number of Preamble Symbols depend on the amount of L1 signalling, i.e. the number of underlying Data Slices and PLPs and L1 TI mode. This clause concentrates on the structure and the syntax of the L1 signalling part 2 rather than the preamble coding and modulation (being described in more detail in clause 8.4). L1 signalling part 2 indicates OFDM parameters of the C2 channel as well as all relevant information for the Data Slices, PLPs and Notch bands.

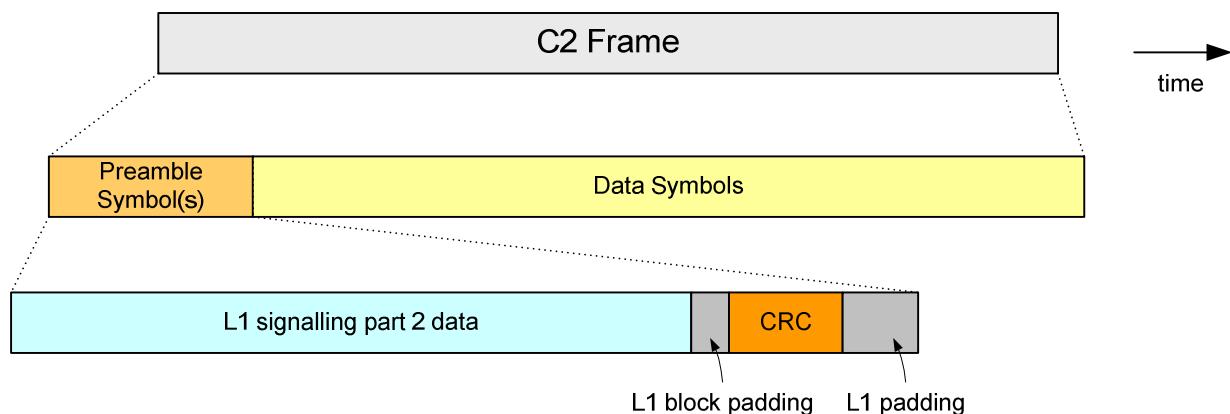

Figure 18: The L1 part 2 signalling structure

8.2 Preamble Header

A fixed length Preamble Header of 32 OFDM Cells shall be inserted in front of the L1 TI-block at each Preamble Symbol as shown in figure 19. All L1 part 2 headers in one C2 Frame shall be same. The Preamble header describes L1-part2 length and TI mode of L1 block. The 16 information bits of the Preamble header are FEC encoded by a Reed-Muller (32,16) code and encoded by QPSK same as the QPSK based FECFrame header in clause 7.2.2.

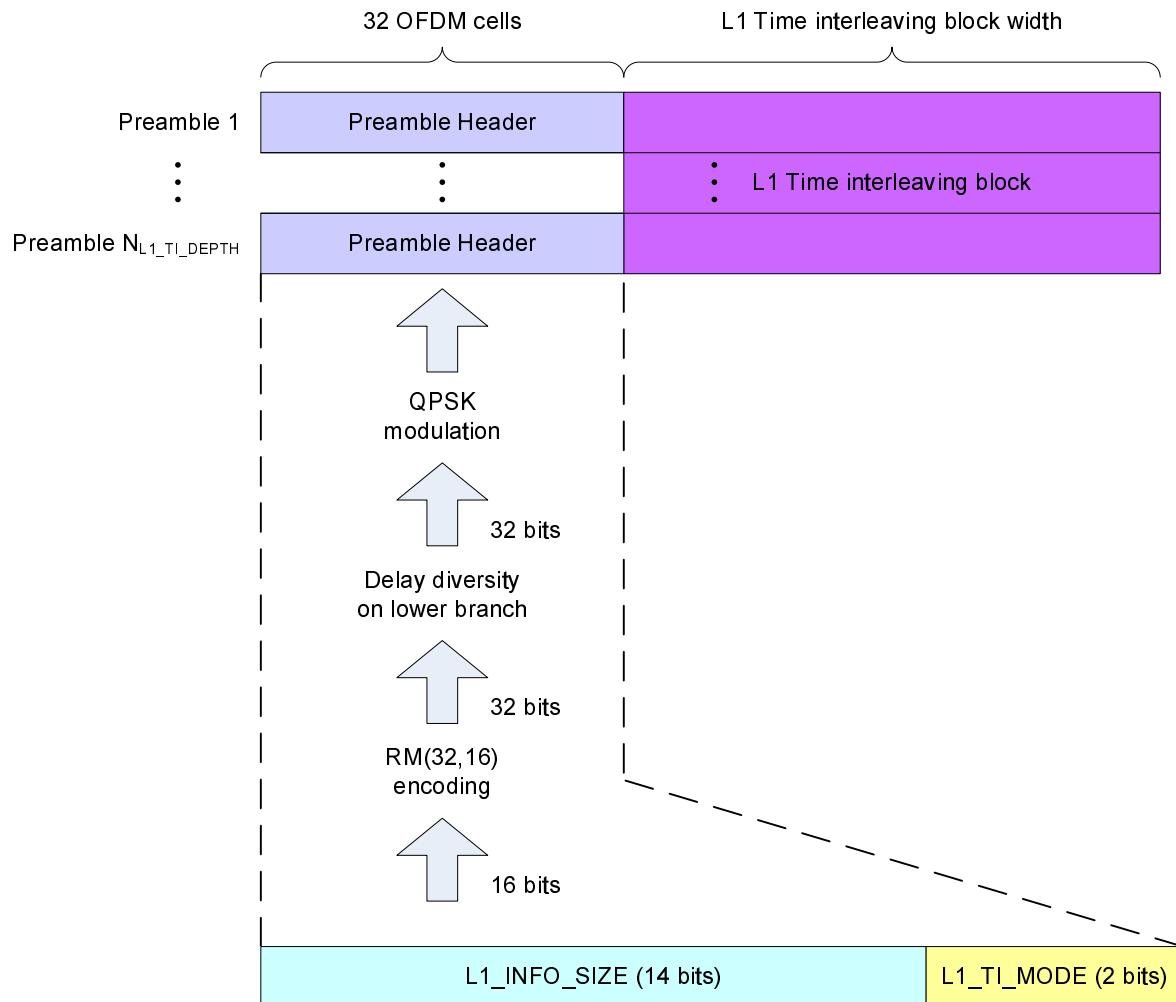

Figure 19: Preamble header generation and signalling fields

L1_INFO_SIZE: This 14-bit field indicates the half size of the L1-part2 including L1 signalling part 2 data and L1 block padding, if present, in bits as shown in figure 20. The value of $K_{L1part2_ex_pad}$ shall be calculated by adding 32 (the length of CRC) to $L1_INFO_SIZE \times 2$.

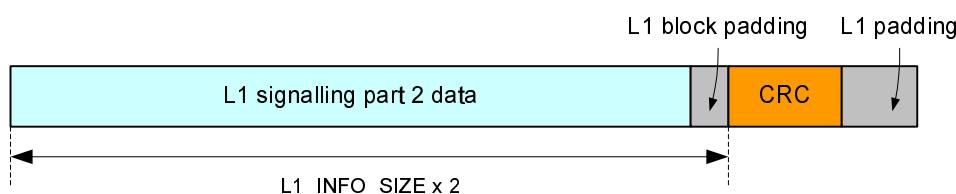

Figure 20: The size indicated by the L1_INFO_SIZE field

L1_TI_MODE: This 2-bit field indicates the mode of time interleaving for L1-part2 of current C2 Frame. The time interleaving mode is signalled according to table 17. See clause 8.5 for more information.

Table 17: Signalling format for the L1_TI_MODE field

Value	Mode
00	No time interleaving
01	Best Fit
10	4 OFDM Symbols
11	8 OFDM Symbols

8.3 L1 signalling part 2 data

Table 18 indicates the detailed use of fields for L1 signalling part 2 data.

NETWORK_ID: This is a 16-bit field which uniquely identifies the current DVB-C2 network.

C2_SYSTEM_ID: This 16-bit field uniquely identifies a C2 System within the DVB-C2 network.

START_FREQUENCY: This 24-bit field indicates the start frequency of the current C2 System by means of the distance from 0 Hz and gives the unsigned integer value in multiples of the carrier spacing of the current C2 System. The value of '0' means 0 Hz. The START_FREQUENCY shall be identical to the OFDM subcarrier with the smallest absolute carrier index $k=K_{min}$ that actually transmits the DVB-C2 preamble for the given C2 system. Additionally, the START_FREQUENCY shall be multiples of the pilot spacing D_x and the START_FREQUENCY shall not change between different C2 frames.

C2_BANDWIDTH: This 16-bit field indicates the bandwidth of the current C2 system. The C2_BANDWIDTH field multiplied with the pilot spacing $D_x + 1$ represents the bandwidth of the C2 system in OFDM subcarriers. The value shall not change between different C2 frames. The bandwidth of the current C2 system is defined by the frequency spacing between the edge pilots next to the most left and the most right Data Slice of the current C2 system.

GUARD_INTERVAL: This 2-bit field indicates the guard interval of the current C2 Frame, according to table 19.

Table 19: Signalling format for the guard interval

Value	Guard interval fraction
00	1/128
01	1/64
10 to 11	Reserved for future use

C2_FRAME_LENGTH: This 10-bit field gives the number of Data Symbols per C2 Frame (L_{data}). The C2 System according to the present document does only allow C2_FRAME_LENGTH = 0x1C0 (448 decimal). All other codes for C2_FRAME_LENGTH are reserved for future use.

L1_PART2_CHANGE_COUNTER: This 8-bit field indicates the number of C2 Frames ahead where the configuration (i.e. the contents of the fields in the L1 signalling part 2 except for the PLP_START and L1_PART2_CHANGE_COUNTER) will change. The next C2 Frame with changes in the configuration is indicated by the value signalled within this field. If this field is set to the value '0', it means that no scheduled change is foreseen. For example, value '1' indicates that there is change in the next C2 Frame.

NUM_DSlice: This 8-bit field indicates the number of Data Slices carried within the current C2 Frame. The minimum value of this field shall be '1'.

NOTE 1: Both the number of Data Slices and the number of PLPs for each Data Slice of a C2 System are chosen such that the overall L1-part2 signalling does not exceed 32 766 bits.

NUM_NOTCH: This 4-bit field indicates the number of Notch bands. If there is no Notch band within the current C2 Frame, this field shall be set to '0'.

The following fields appear in the Data Slice loop:

- **DSLICE_ID:** This 8-bit field uniquely identifies a Data Slice within the C2 System.
- **DSLICE_TUNE_POS:** This field indicates the tuning position of the associated Data Slice relative to the START_FREQUENCY. Its bit width shall be 13 bits or 14 bits according to the GUARD_INTERVAL value. When GUARD_INTERVAL is '00', the bit width of this field shall be 13 bits and indicate the tuning position in multiples of 24 carriers within current C2 Frame. Otherwise the bit width of this field shall be 14 bits and indicate the tuning position in multiples of 12 carriers within the current C2 Frame relative to the START_FREQUENCY. DSLICE_TUNE_POS must be a value at least 1 704 carriers from the edge of a broadband notch or the start or end of the C2 system.
- **DSLICE_OFFSET_LEFT:** This field indicates the start position of the associated Data Slice by means of the distance to the left from the tuning position and shall be two's complement integer of 8 bits or 9 bits according to the GUARD_INTERVAL value. When GUARD_INTERVAL is '00', this field shall be two's complement integer of 8 bits and indicate the distance from the tuning position in multiples of 24 carriers within current C2 Frame. Otherwise this field shall be two's complement integer of 9 bits and indicate the distance from the tuning position in multiples of 12 carriers within current C2 Frame.

- **DSLICE_OFFSET_RIGHT:** This field indicates the end position of the associated Data Slice by means of the distance to the right from the tuning position and shall be two's complement integer of 8 bits or 9 bits according to the GUARD_INTERVAL value. When GUARD_INTERVAL is '00', this field shall be two's complement integer of 8 bits and indicate the distance from the tuning position in multiples of 24 carriers within current C2 Frame. Otherwise this field shall be two's complement integer of 9 bits and indicate the distance from the tuning position in multiples of 12 carriers within current C2 Frame.

NOTE 2: DSLICE_OFFSET_LEFT and DSLICE_OFFSET_RIGHT may both have positive or negative values, which means that the complete Data Slice is left or right hand side of the tuning position.

- **DSLICE_TI_DEPTH:** This 2-bit field indicates the time interleaving depth within the associated Data Slice according to table 20.

Table 20: Signalling format for the time interleaving depth

Value	TI depth
00	No time interleaving
01	4 OFDM Symbols
10	8 OFDM Symbols
11	16 OFDM Symbols

- **DSLICE_TYPE:** This 1-bit field indicates the type of the associated Data Slice according to table 21. The Data Slice Type 1 is only for the transmission of a single PLP with fixed modulation and coding parameters within a Data Slice. See clause 7 for more information.

Table 21: Signalling format for the Data Slice type

Value	Data Slice type
0	Data Slice Type 1
1	Data Slice Type 2

The following field appears only if the DSLICE_TYPE is '1'.

- **FEC_HEADER_TYPE:** This 1-bit field indicates the type of the FECFrame header within the associated Data Slice according to table 22.

Table 22: Signalling format for the FECFrame header type

Value	FECFrame header type
0	Robust mode
1	High efficiency mode

- **DSLICE_CONST_CONF:** This 1-bit field indicates whether the configuration of the associated Data Slice is variable or fixed. If this field is set to value '1', the configuration of the associated Data Slice shall not change. Otherwise this field shall be set to '0'. A value of '1' is only allowed in combination with Data Slices Type 2.
- **DSLICE_LEFT_NOTCH:** This 1-bit field indicates the presence of the left neighboured Notch band of the associated Data Slice. If the start of associated Data Slice is neighboured by Notch band, this field shall be set to '1'. Otherwise this field shall be set to '0'.

NOTE 3: The DSLICE_LEFT_NOTCH field can be used by a receiver to assist in finding the number of Data Cells of the current Data Slice. The continual pilots positioned on the edge of the Notch band change the number of Data Cells of its right neighboured Data Slice. See clause 9.6.4.1 for more information.

- **DSLICE_NUM_PLP:** This 8-bit field indicates the number of PLPs carried within the associated Data Slice. The minimum value of this field shall be '1'.

NOTE 4: Both the number of Data Slices and the number of PLPs for each Data Slice of a C2 System are chosen such, that the overall L1-part2 signalling does not exceed 32 766 bits.

The following fields appear in the PLP loop:

- **PLP_ID:** This 8-bit field identifies a PLP within the C2 System.
- **PLP_BUNDLED:** This 1-bit field indicates whether the associated PLP is bundled with other PLP(s) or not within the current C2 System. If the associated PLP is bundled, this field shall be set to '1'. Otherwise this field shall be set to '0'.
- **PLP_TYPE:** This 2-bit field indicates the type of the associated PLP. PLP_TYPE shall be signalled according to table 23.

Table 23: Signalling format for the PLP_TYPE field

Value	PLP type
00	Common PLP
01	Grouped Data PLP
10	Normal Data PLP
11	Reserved for future use

- **PLP_PAYLOAD_TYPE:** This 5-bit field indicates the type of the payload data carried by the associated PLP. PLP_PAYLOAD_TYPE shall be signalled according to table 24. See clause 5.1.1 for more information.

Table 24: Signalling format for the PLP_PAYLOAD_TYPE field

Value	Payload type
00000	GFPS
00001	GCS
00010	GSE
00011	TS
00100 to 11111	Reserved for future use

The following field appears only if the PLP_TYPE is '00' or '01'.

- **PLP_GROUP_ID:** This 8-bit field identifies with which PLP group within the C2 System the current PLP is associated. This can be used by a receiver to link the Data PLP to its associated Common PLP, which will have the same PLP_GROUP_ID.

The following fields appear only if the DSlice_TYPE is '0', i.e. the Data Slice Type 1 is used.

- **PLP_START:** This 14-bit field indicates the start position of the first complete XFECframe of the associated PLP within the current C2 Frame. It uses the cell addressing scheme defined in clause 9.4.3.
- **PLP_FEC_TYPE:** This 1-bit field indicates the FEC type used by the associated PLP. The FEC type shall be signalled according to table 25.
- **PLP_MOD:** This 3-bit field indicates the modulation used by the associated PLP. The modulation shall be signalled according to table 25.

The signalling is valid for the first XFECframe starting within the DVB-C2 frame.

Table 25: Signalling format for the PLP_MOD and the PLP_COD fields

PLP_FEC_TYPE	PLP_MOD	PLP FEC type	Modulation	XFECFrame Length
0	000	16K LDPC	Reserved	NA
	001		16QAM	4 050
	010		64QAM	2 700
	011		256QAM	2 025
	100		1024QAM	1 620
	101		4096QAM	1 350
	110		Reserved	1 158
	111		Reserved	1 013
	000		Reserved	900
1	001	64K LDPC	16QAM	16 200
	010		64QAM	10 800
	011		256QAM	8 100
	100		1024QAM	6 480
	101		4096QAM	5 400
	110		Reserved	4 629
	111		Reserved	4 050

NOTE 5: The XFECframe length of the associated PLP is determined by PLP_FEC_TYPE and PLP_MOD as shown in table 25.

- **PLP_COD:** This 3-bit field indicates the code rate used by the associated PLP. The code rate shall be signalled according to table 26. When PLP_COD is '101', the code rate is determined by PLP_FEC_TYPE. If PLP_FEC_TYPE is set to '0', PLP_COD of '101' means the code rate of 8/9. Otherwise it means the code rate of 9/10. Please note that not all possible PLP_MOD and PLP_COD combinations are supported (see tables 11(a) and 11(b)).

Table 26: Signalling format for the code rate

Value	Code rate
000	Reserved for future use
001	2/3
010	3/4
011	4/5
100	5/6
101	8/9 (16K LDPC code) 9/10 (64K LDPC code)
110 to 111	Reserved for future use

- **PSI/SI_REPROCESSING:** This 1-bit field indicates whether PSI/SI reprocessing is performed or not. This can be used by a receiver to recognize if it can rely on the related PSI/SI parts. When PSI/SI reprocessing is performed, this field shall be set to '1', otherwise it shall be set to '0'.

The following fields appear only if the PSI/SI_REPROCESSING is '0'.

- **transport_stream_id:** This is a 16-bit field which serves as a label for identification of this TS from any other multiplex within the delivery system (see also [i.4]).
- **original_network_id:** This 16-bit field gives the label identifying the network_id of the originating delivery system (see also [i.4]).
- **RESERVED_1:** This 8-bit field is reserved for future use.
- **RESERVED_2:** This 8-bit field is reserved for future use.

The following fields appear in the Notch loop:

- **NOTCH_START:** This field indicates the start position of the associated Notch band and gives the unsigned integer value relative to the START_FREQUENCY. Its bit width shall be 13 bits or 14 bits according to the GUARD_INTERVAL value. When GUARD_INTERVAL is '00', the bit width of this field shall be 13 bits and indicate the start position in multiples of 24 carriers within the current C2 Frame. Otherwise the bit width of this field shall be 14 bits and indicate the start position in multiples of 12 carriers within the current C2 Frame.
- **NOTCH_WIDTH:** This field indicates the width of the associated Notch band and gives the unsigned integer value. Its bit width shall be 8 bits or 9 bits according to the value of GUARD_INTERVAL. When GUARD_INTERVAL is '00', the bit width of this field shall be 8 bits and indicate the width in multiples of 24 carriers within the current C2 Frame. Otherwise the bit width of this field shall be 9 bits and indicate the width in multiples of 12 carriers within the current C2 Frame.
- **RESERVED_3:** This 8-bit field is reserved for future use.
- **RESERVED_TONE:** This 1-bit field indicates whether some carriers are reserved. When there are reserved carriers within the current C2 Frame, this bit shall be set to '1', otherwise it shall be set to '0'. The positions of reserved carriers for reserved tones within a C2 Frame are given in clause 9.7.
- **RESERVED_4:** This 16-bit field is reserved for future use.

8.3.1 L1 block padding

This 1-bit field is inserted following the L1 signalling part 2 data to ensure that the length of L1 signalling part 2 including L1 signalling part2 data and L1 block padding is a multiple of 2 (see figure 20). If the total length of L1 signalling part 2 is not a multiple of 2, this field shall be inserted at the end of the L1 signalling part 2 data. The value of the L1 block padding bit, if any, shall be set to '0'.

8.3.2 CRC for the L1 signalling part 2

A 32-bit error detection code is applied to the entire L1 signalling part 2 including L1 signalling part 2 data and L1 block padding. The location of the CRC field can be found from the length of the L1 signalling part 2, which can be calculated using L1_INFO_SIZE in the Preamble header. The CRC-32 is defined in annex E.

8.3.3 L1 padding

This variable-length field is inserted following the L1 signalling part 2 CRC field to ensure that multiple LDPC blocks of the L1 signalling part 2 have the same information size when the L1 signalling part 2 is segmented into multiple blocks and these blocks are separately encoded. Details of how to determine the length of this field are described in clause 8.4. The value of the L1 padding bits, if any, are set to '0'.

8.4 Modulation and error correction coding of the L1 part 2 data

8.4.1 Overview

The L1 part 2 data is protected by a concatenation of BCH outer code and LDPC inner code. The L1 part 2 data shall be first BCH-encoded. The length of the L1 part 2 data bits varies depending on the complexity of the underlying Data Slices. The L1 part 2 data can be segmented into multiple blocks. A segmented L1 part 2 data has a length less than $K_{bch} = 7\ 032$. Therefore, a shortening operation (zero padding) is required for BCH or LDPC encoding. After BCH encoding with zero padded information, the BCH parity bits of the L1-part2 data shall be appended to the L1 part 2 data. The concatenated L1 part 2 data and BCH parity bits are further protected by a shortened and punctured 16K LDPC code with code rate 1/2 ($N_{ldpc} = 16\ 200$). Note that the effective code rate of the 16K LDPC code with code rate 1/2 is 4/9, where the effective code rate is defined as the information length over the encoder output length. Details of how to shorten and puncture the 16K LDPC code are described in clauses 8.4.3.1, 8.4.3.4 and 8.4.3.5. Each coded L1 signalling part 2 shall be bit-interleaved (see clause 8.4.3.6) and then shall be mapped onto constellations (see clause 8.4.4). Note that only 16QAM is used for encoding of L1 signalling part 2. The conceptual processing of coding and modulation of L1 signalling part 2 is shown in figure 21.

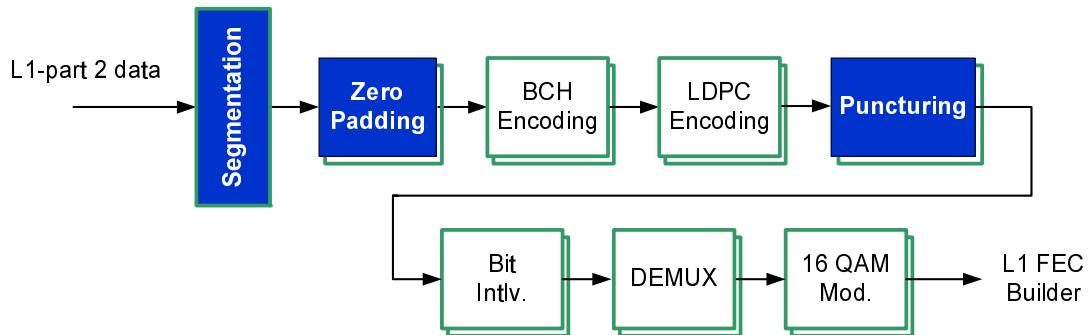

Figure 21: Encoding and Modulation of L1 signalling part 2

Since the length of L1 signalling part 2 is variable, the resulting number of needed L1 frames is also varying. Each L1 FECFrame packet corresponds to one L1 block within an OFDM Symbol. As soon as more than one L1 FECFrame packet is needed, the same number of Preamble Symbols in consecutive OFDM Symbols is needed. If the length of L1 part 2 data exceeds a predetermined number $N_{L1part2_max_per_Symbol}$ (see clause 8.4.2), the L1 part 2 data shall be divided into equidistant blocks. $N_{L1part2_max_per_Symbol}$ means the maximum number of L1 information bits for transmitting the coded L1 signalling part 2 through one OFDM Symbol. Figures 22 (a) and 22 (b) show the handling example for the following cases:

- a) L1 part 2 fits into one L1 part 2 LDPC FECFrame (see figure 22 (a)).
- b) L1 part 2 exceeds one L1 part 2 LDPC FECFrame (see figure 22 (b)).

Details of the segmentation are described in clause 8.4.2.

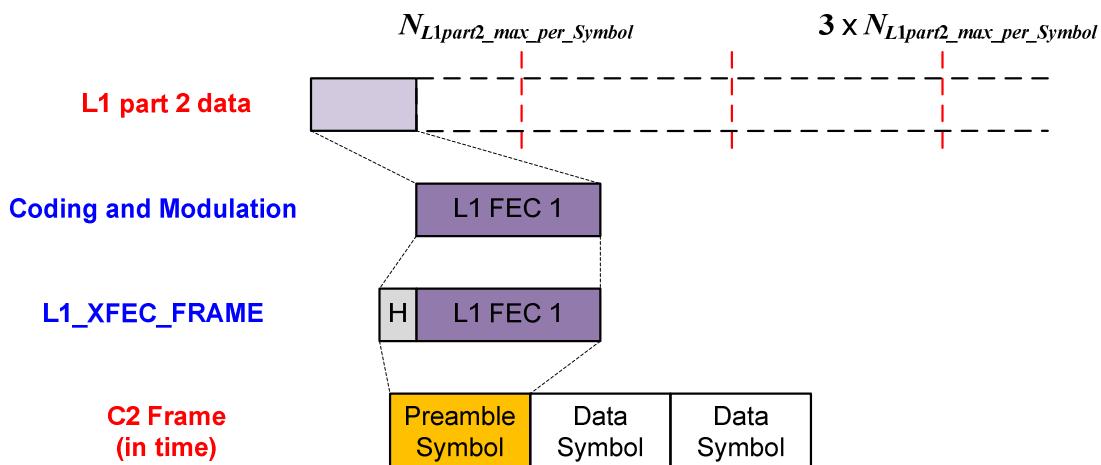

Figure 22(a): L1 part 2 fits into one L1 part 2 LDPC FECFrame

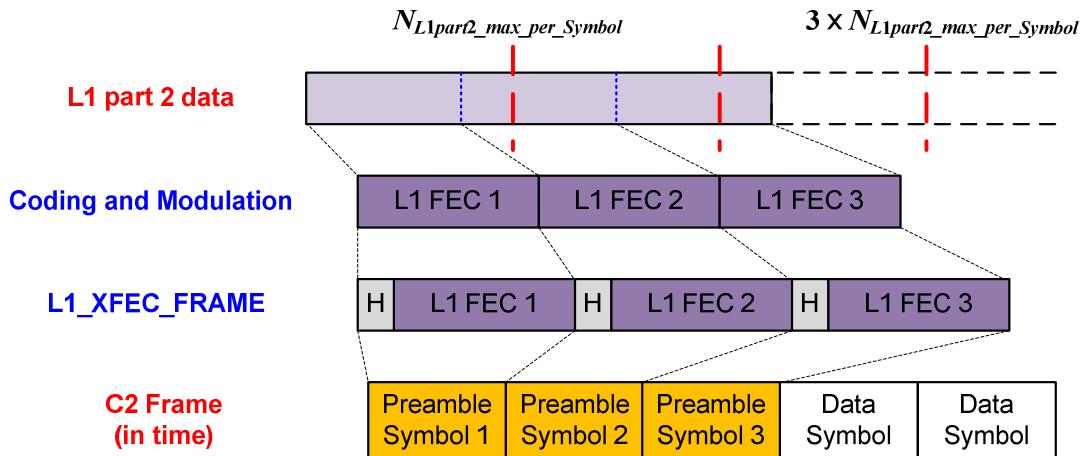

Figure 22(b): L1 part 2 exceeds one L1 part 2 LDPC FECFrame

According to the signalling field for time interleaving in L1 signalling part 2 header, 'L1_TI_MODE', the time interleaving can be applied to L1 FECFrame (see clause 8.2). Details of the time interleaving are described in clause 8.5.

If there are cells remaining from each Preamble Symbol after mapping each L1 FECFrame to the Preamble Symbol, the L1 FECFrame including L1 part 2 header is cyclically repeated until the complete preamble block is filled, as shown in figure 23. The information on the structure of a cyclically repeated L1 FECFrame in a Preamble Symbol is obtained by detecting and extracting of L1 part 2 header.

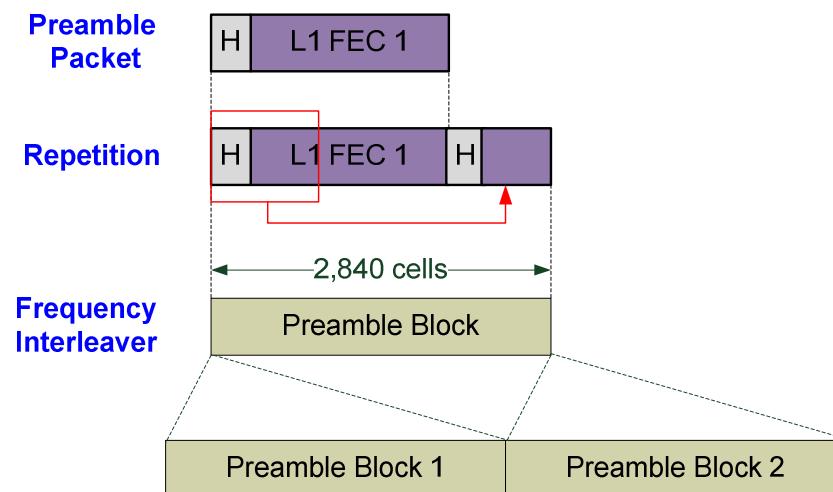

Figure 23: Allocation of L1 FECFrame to L1 blocks (Preamble blocks)

8.4.2 Parameters for FEC encoding of L1 part 2 data

The number of L1 part 2 data bits is variable and the bits shall be transmitted over one or multiple 16K LDPC blocks depending on the length of the L1 part 2 data. The number of LDPC blocks for the L1 part 2 data, $N_{L1part2_FEC_Block}$, shall be determined as follows:

$$N_{L1part2_FEC_Block} = \left\lceil \frac{K_{L1part2_ex_pad}}{N_{L1part2_max_per_Symbol}} \right\rceil,$$

where $\lceil x \rceil$ means the smallest integer larger than or equal to x , and $K_{L1part2_ex_pad}$, which can be found by adding 32 to the parameter $2 \times \text{L1_INFO_SIZE}$, denotes the number of information bits of the L1 part 2 signalling excluding the padding field, L1_PADDING (see clause 8.3.3).

$N_{L1part2_max_per_Symbol}$ is 4 759 which is chosen as the minimum value among the maximum values of K_i satisfying that $N_{L1part2}(K_i)$ is less than or equal to $N_{L1part2_Cells} \times \eta_{MOD}$, for $i = 1, 2, \dots, 8$. Here, $N_{L1part2_Cells}$ ($= 2\ 808$) denotes the number of available cells for L1 signalling part 2 in one OFDM Symbol, η_{MOD} denotes the modulation order 4 for 16QAM, and $N_{L1part2}(K_i)$ is the length of the encoded L1 signalling part 2 with K_i information bits for $N_{L1part2_FEC_Block} = i$. Then, the length of L1_PADDING field, $K_{L1part2_PADDING}$ shall be calculated as:

$$K_{L1part2_PADDING} = \left\lceil \frac{K_{L1part2_ex_pad}}{N_{L1part2_FEC_Block}} \right\rceil \times N_{L1part2_FEC_Block} - K_{L1part2_ex_pad}.$$

The final length of the whole L1 signalling part 2 including the padding field, $K_{L1part2}$ shall be set as follows:

$$K_{L1part2} = K_{L1part2_ex_pad} + K_{L1_PADDING}.$$

The number of information bits in each of $N_{L1part2_FEC_Block}$ blocks, K_{sig} is then defined by:

$$K_{sig} = \frac{K_{L1part2}}{N_{L1part2_FEC_Block}}.$$

Each block with information size of K_{sig} is protected by a concatenation of BCH outer codes and LDPC inner codes. Each block shall be first BCH-encoded, where its N_{bch_parity} ($= 168$) BCH parity check bits shall be appended to information bits of each block. The concatenated information bits of each block and BCH parity check bits are further protected by a shortened and punctured 16K LDPC code with code rate 1/2 (effective code rate: $R_{eff_16K_LDPC_1_2} = 4/9$). Details of how to shorten and puncture the 16K LDPC code are described in clauses 8.4.3.1, 8.4.3.4 and 8.4.3.5.

For a given K_{sig} and modulation order (16QAM is used for the L1 signalling part 2), N_{punc} shall be determined by the following steps:

Step 1) Calculate the number of puncturing bits as follows:

$$N_{punc_temp} = \left\lfloor \frac{6}{5} \times (K_{bch} - K_{sig}) \right\rfloor,$$

where K_{bch} is 7 032 for the 16K LDPC code with code rate 1/2, and the operation $\lfloor x \rfloor$ means the largest integer less than or equal to x . A temporary size of puncturing bits is calculated by multiplying the shortening length by a fixed number 6/5.

The effective LDPC code rate of the L1 signalling part 2, $R_{eff_L1part2}$ is always lower than or equal to $R_{eff_16K_LDPC_1_2} \cdot R_{eff_L1part2}$ tends to decrease as the information length K_{sig} decreases. This rate control ensures that the receiving coverage for the L1 signalling part 2 is preserved after the shortening and puncturing. The multiplicative coefficient 6/5 is the ratio of the puncturing length to the shortening length and it is chosen as the best value among those formed of $(B+1)/B$ for an integer B .

Step 2) $N_{L1part2_temp} = K_{sig} + N_{bch_parity} + N_{ldpc} \times (1 - R_{eff_16K_LDPC_1_2}) - N_{punc_temp}$.

For the 16K LDPC code with effective code rate 4/9, $N_{ldpc} \times (1 - R_{eff_16K_LDPC_1_2}) = 9\ 000$.

Step 3) According to the value of time interleaving field, 'L1_TI_MODE', in the L1 part 2 header (see clause 8.2), $N_{L1part2}$ shall be calculated as follows:

$$N_{L1part2} = \begin{cases} \text{If } L1_TI_MODE = 00 \text{ or } 01, \\ \left\lceil \frac{N_{L1part2_temp}}{2\eta_{MOD} \times N_{L1part2_FEC_Block}} \right\rceil \times 2\eta_{MOD} \times N_{L1part2_FEC_Block} \\ \text{Otherwise,} \\ \left\lceil \frac{N_{L1part2_temp}}{2\eta_{MOD} \times N_{L1_TI_Depth}} \right\rceil \times 2\eta_{MOD} \times N_{L1_TI_Depth} \end{cases}$$

where η_{MOD} is 4 for 16QAM, and $N_{L1_TI_Depth}$ is 4 and 8 for $L1_TI_MODE = 10$ and 11 , respectively, as shown in clause 8.2.

This step guarantees that $N_{L1part2}$ is a multiple of the number of columns of the bit interleaver, $2\eta_{MOD}$, (described in clause 8.4.3.6) and that $N_{L1part2}/\eta_{MOD}$ is a multiple of the number of OFDM Symbols for transmitting L1 signalling part 2. Note that the number of OFDM Symbols for transmitting L1 signalling part 2 are $N_{L1part2_FEC_Block}$ and $N_{L1_TI_Depth}$ for ' $L1_TI_MODE = 00, 01$ ' and ' $L1_TI_MODE = 10, 11$ ', respectively.

Step 4) $N_{punc} = N_{punc_temp} - (N_{L1part2} - N_{L1part2_temp})$.

$N_{L1part2}$ is the number of the encoded bits for each information block. After the shortening and puncturing, the encoded

bits of each block shall be mapped to $N_{MOD_per_Block} = \frac{N_{L1part2}}{\eta_{MOD}}$ modulated symbols. The total number of the

modulation symbols of $N_{L1part2_FEC_Block}$ blocks, N_{MOD_Total} is $N_{MOD_Total} = N_{MOD_per_Block} \times N_{L1part2_FEC_Block}$.

When 16QAM is used, a bit interleaving shall be applied across each LDPC block. Details of how to interleave the encoded bits are described in clause 8.4.3.6. Demultiplexing is then performed as described in clause 8.4.4.1. The demultiplexer output is then mapped to a 16QAM constellation, as described in clause 8.4.4.2.

8.4.3 FEC Encoding

8.4.3.1 Zero padding of BCH information bits

K_{sig} bits defined in clause 8.4.2 shall be encoded into a 16K ($N_{ldpc} = 16\ 200$) LDPC codeword after BCH encoding.

Since the K_{sig} is always less than the number of BCH information bits ($= K_{bch} = 7\ 032$) for a given code rate 1/2, the BCH code shall be shortened. A part of the information bits of the 16K LDPC code shall be padded with zeros in order to fill K_{bch} information bits. The padding bits shall not be transmitted.

All K_{bch} BCH information bits, denoted by $\{m_0, m_1, \dots, m_{K_{bch}-1}\}$, are divided into N_{group} ($= K_{ldpc}/360$) groups as follows:

$$X_j = \left\{ m_k \middle| j = \left\lfloor \frac{k}{360} \right\rfloor, 0 \leq k < K_{bch} \right\} \text{ for } 0 \leq j < N_{group},$$

where X_j represents the j th bit group. The code parameters (K_{bch}, K_{ldpc}) are given in table 27 for L1 part 2 data.

Table 27: Code parameters (K_{bch}, K_{ldpc}) for L1 part 2 data

	K_{bch}	K_{ldpc}
L1 signalling part 2	7 032	7 200

For $0 \leq j \leq N_{group} - 2$, each bit group X_j has 360 bits and the last bit group $X_{N_{group}-1}$ has $360 - (K_{ldpc} - K_{bch}) = 192$ bits, as illustrated in figure 24.

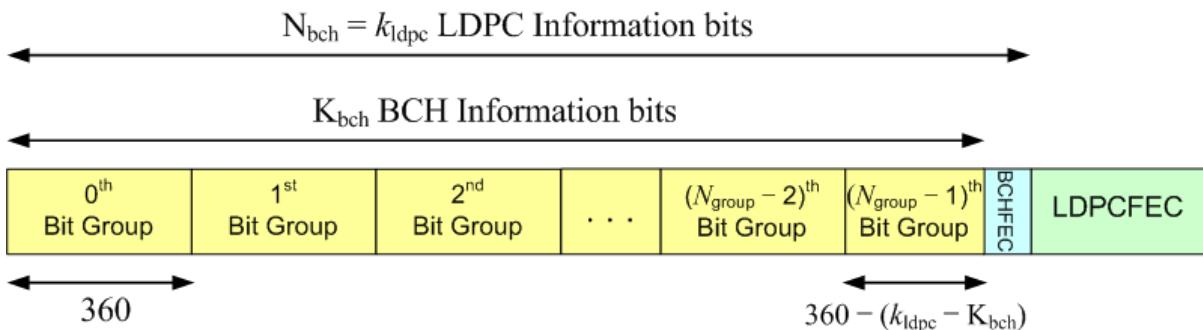

Figure 24: Format of data after LDPC encoding of L1 signalling part 2

For the given K_{sig} , the number of zero-padding bits is calculated as $(K_{bch} - K_{sig})$. Then, the shortening procedure is as follows:

- Step 1) Compute the number of groups in which all the bits shall be padded, N_{pad} such that:

$$\text{If } 0 < K_{sig} \leq 360, N_{pad} = N_{group} - 1$$

$$\text{Otherwise, } N_{pad} = \left\lceil \frac{K_{bch} - K_{sig}}{360} \right\rceil$$

- Step 2) For N_{pad} groups $X_{\pi_s(0)}, X_{\pi_s(1)}, \dots, X_{\pi_s(m-1)}, X_{\pi_s(N_{pad}-1)}$, all information bits of the groups shall be padded with zeros. Here, π_s is a permutation operator depending on the code rate and modulation order, described in table 28.

- Step 3) If $N_{pad} = N_{group} - 1$, $(360 - K_{sig})$ information bits in the last part of the bit group $X_{\pi_s(N_{group}-1)}$ shall be additionally padded. Otherwise, for the group $X_{\pi_s(N_{pad})}, (K_{bch} - K_{sig} - 360 \times N_{pad})$ information bits in the last part of $X_{\pi_s(N_{pad})}$ shall be additionally padded.

- Step 4) Finally, K_{sig} information bits are sequentially mapped to bit positions which are not padded in K_{bch} BCH information bits, $\{m_0, m_1, \dots, m_{K_{bch}-1}\}$ by the above procedure.

EXAMPLE: Suppose for example the value of K_{sig} is 3 986. In this case, from step (1), 8 groups would have all zero padded bits, and from step (2) these groups would be those with numbers 18, 17, 16, 15, 14, 13, 12, 11. From step (3), an additional 166 bits would be zero padded in Group 4. Finally from step (4) the 3 986 bits would be mapped sequentially to Groups 0, 1, 2, 3 (360 bits each), the first part of Group 4 (194 bits), Groups 5, 6, 7, 8, 9, 10 (360 bits each), and group 19 (192 bits). Figure 25 illustrates the shortening of the BCH information part in this case, i.e. filling BCH information bit positions not zero padded with K_{sig} information bits.

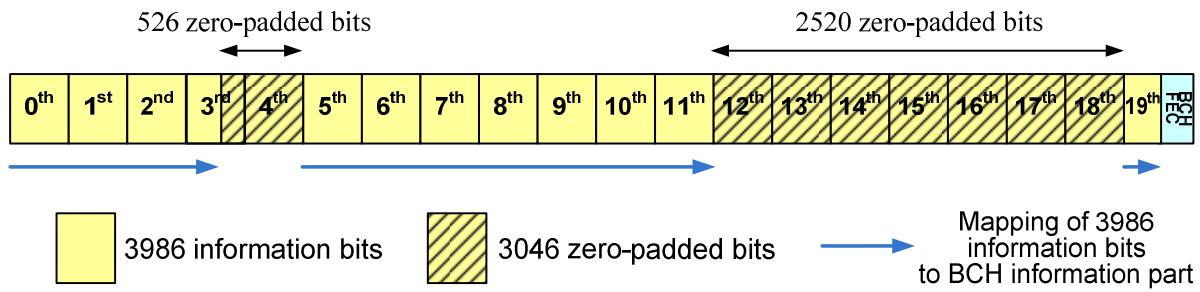

Figure 25: Example of shortening of BCH information part

Table 28: Permutation sequence of information bit group to be padded for L1 signalling part 2

Modulation and code rate		N_{group}	$\pi_S(j) \quad (0 \leq j < N_{group})$									
			$\pi_S(0)$	$\pi_S(1)$	$\pi_S(2)$	$\pi_S(3)$	$\pi_S(4)$	$\pi_S(5)$	$\pi_S(6)$	$\pi_S(7)$	$\pi_S(8)$	$\pi_S(9)$
16QAM	1/2	20	18	17	16	15	14	13	12	11	4	10
			9	8	7	3	2	1	6	5	19	0

8.4.3.2 BCH encoding

The K_{bch} information bits (including the $K_{bch} - K_{sig}$ zero padding bits) shall first be BCH encoded according to clause 6.1.1 to generate $N_{bch} = K_{ldpc}$ output bits ($i_0 \dots i_{N_{bch}-1}$).

8.4.3.3 LDPC encoding

The $N_{bch} = K_{ldpc}$ output bits ($i_0 \dots i_{N_{bch}-1}$) from the BCH encoder, including the $(K_{bch} - K_{sig})$ zero padding bits and the $(K_{ldpc} - K_{bch})$ BCH parity bits form the K_{ldpc} information bits $\mathbf{I} = (i_0, i_1, \dots, i_{K_{ldpc}-1})$ for the LDPC encoder. The LDPC encoder shall systematically encode the K_{ldpc} information bits onto a codeword \mathbf{A} of size N_{ldpc} :

$$\mathbf{A} = (i_0, i_1, \dots, i_{K_{ldpc}-1}, p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1}) \text{ according to clause 6.1.2.}$$

8.4.3.4 Puncturing of LDPC parity bits

When the shortening is applied to encoding of the signalling bits, some LDPC parity bits shall be punctured after the LDPC encoding. These punctured bits shall not be transmitted.

All $N_{ldpc} - K_{ldpc}$ LDPC parity bits, denoted by $\{p_0, p_1, \dots, p_{N_{ldpc}-K_{ldpc}-1}\}$, are divided into Q_{ldpc} parity groups where each parity group is formed from a sub-set of the $N_{ldpc} - K_{ldpc}$ LDPC parity bits as follows:

$$P_j = \left\{ p_k \mid k \bmod Q_{ldpc} = j, 0 \leq k < N_{ldpc} - K_{ldpc} \right\} \quad \text{for} \quad 0 \leq j < Q_{ldpc},$$

where P_j represents the j th parity group and Q_{ldpc} is given in table 5(b). Each group has $(N_{ldpc} - K_{ldpc})/Q_{ldpc} = 360$ bits, as illustrated in figure 26.

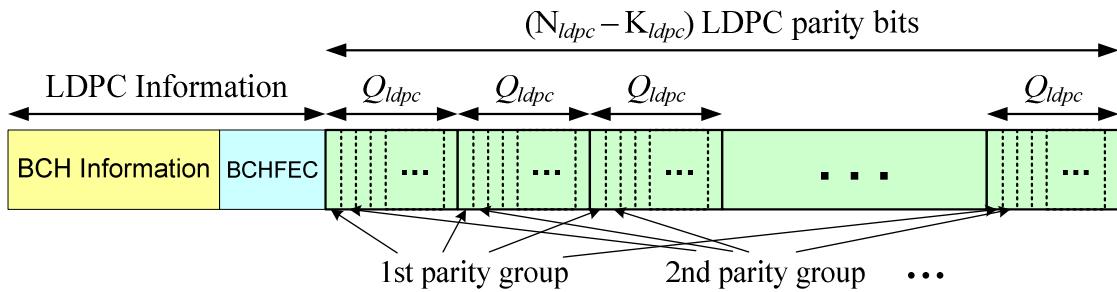

Figure 26: Parity bit groups in an FEC block

For the number of parity bits to be punctured, N_{punc} given in clause 8.4.2.

Step 1) Compute the number of groups in which all parity bits shall be punctured, N_{punc_groups} such that:

$$N_{punc_groups} = \left\lfloor \frac{N_{punc}}{360} \right\rfloor \text{ for } 0 \leq N_{punc} < N_{ldpc} - K_{ldpc}.$$

Step 2) For N_{punc_groups} parity bit groups $P_{\pi_p(0)}, P_{\pi_p(1)}, \dots, P_{\pi_p(N_{punc_groups}-1)}$, all parity bits of the groups shall be punctured. Here, π_p is a permutation operator depending on the code rate and modulation order, described in table 29.

Step 3) For the group $P_{\pi_p(N_{punc_groups})}, (N_{punc} - 360 \times N_{punc_groups})$ parity bits in the first part of the group shall be additionally punctured.

Table 29: Permutation sequence of parity group to be punctured for L1 signalling part 2

Modulation and code rate		Order of parity group to be punctured, { $\pi_p(j), 0 \leq j < Q_{ldpc} = 25$ }												
		$\pi_p(0)$	$\pi_p(1)$	$\pi_p(2)$	$\pi_p(3)$	$\pi_p(4)$	$\pi_p(5)$	$\pi_p(6)$	$\pi_p(7)$	$\pi_p(8)$	$\pi_p(9)$	$\pi_p(10)$	$\pi_p(11)$	$\pi_p(12)$
$\pi_p(13)$	$\pi_p(14)$	$\pi_p(15)$	$\pi_p(16)$	$\pi_p(17)$	$\pi_p(18)$	$\pi_p(19)$	$\pi_p(20)$	$\pi_p(21)$	$\pi_p(22)$	$\pi_p(23)$	$\pi_p(24)$	-		
16QAM	1/2	6	4	13	9	18	8	15	20	5	17	2	22	24
		7	12	1	16	23	14	0	21	10	19	11	3	-

8.4.3.5 Removal of zero padding bits

The $(K_{bch} - K_{sig})$ zero padding bits are removed and shall not be transmitted. This leaves a word consisting of the K_{sig} information bits, followed by the 168 BCH parity bits and $(N_{ldpc} - K_{ldpc} - N_{punc})$ LDPC parity bits.

8.4.3.6 Bit interleaving for L1 signalling part 2

When 16QAM modulation is used for the L1 signalling part 2, the LDPC codeword of length $N_{L1part2}$, consisting of K_{sig} information bits, 168 BCH parity bits, and $(9\ 000 - N_{punc})$ LDPC parity bits, shall be bit-interleaved using a block interleaver. The configuration of the bit interleaver for the chosen 16QAM modulation is specified in table 30.

Table 30: Bit Interleaver structure

Modulation and code rate	Rows Nr	Columns Nc
16QAM	$\frac{1}{2}$	$N_{L1part2} / 8$

The LDPC codeword is serially written into the interleaver column-wise, and serially read out row-wise (the MSB of the L1 signalling part 2 is read out first) as shown in figure 27.

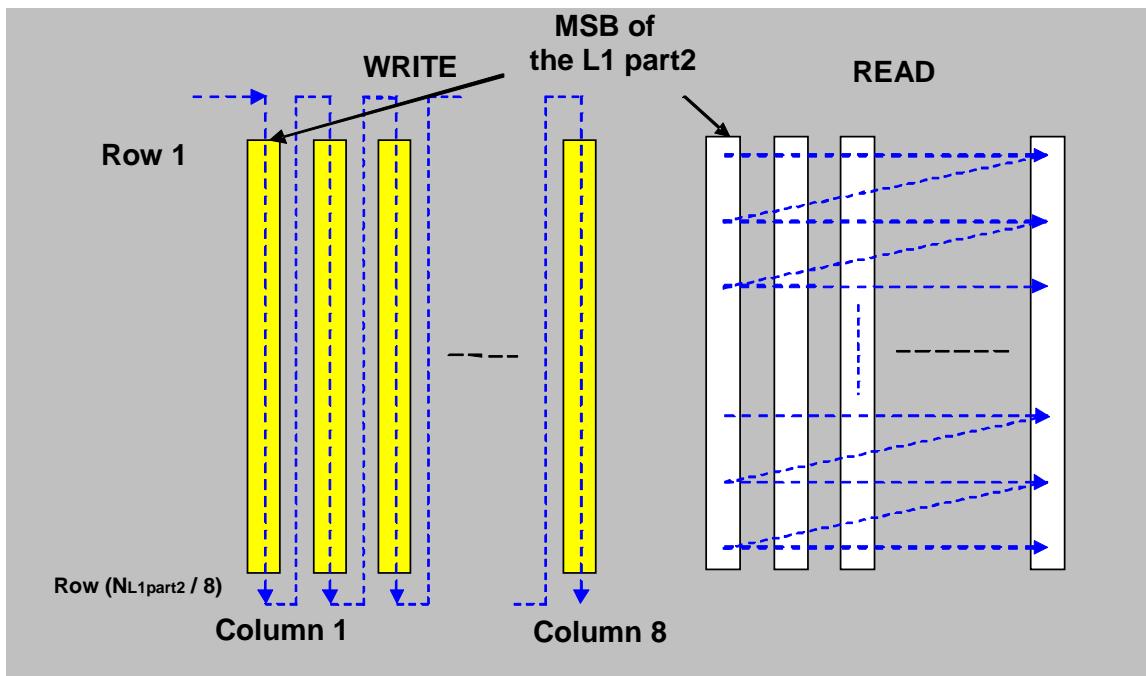

Figure 27: Bit interleaving scheme for L1 part 2 (16QAM)

8.4.4 Mapping bits onto constellations

Each bit-interleaved LDPC codeword shall be mapped onto constellations. The L1 signalling part 2 is first demultiplexed into cell words according to clause 8.4.4.1 and then the cell words are mapped into constellations according to clause 8.4.4.2.

8.4.4.1 Demultiplexing of L1 signalling part 2

Each bit-interleaved LDPC codeword, a sequence of $N_{L1part2}$ ($= K_{sig} + 168 + 9\,000 - N_{punc}$) bits shall be mapped onto constellations by first demultiplexing the input bits into parallel cell words and then mapping these cell words into constellation values. The number of output Data Cells and the effective number of bits per cell, η_{MOD} are defined in table 31.

The input bit-stream v_{di} is demultiplexed into $N_{substreams}$ sub-streams $b_{e,do}$, as shown in figure 13 in clause 6.2.1. The value of $N_{substreams}$ is also defined in table 31. Details of demultiplexing are described in clause 6.2.1. For 16QAM, the parameters for demultiplexing of bits to cells are the same as that of table 10(a) in clause 6.2.1.

Table 31: Parameters for bit-mapping into constellations

Modulation mode	η_{MOD}	Number of output Data Cells	Number of sub-streams, $N_{substreams}$
16QAM	4	$N_{L1part2} / 4$	8

For 16QAM, the output words from the demultiplexing of width $N_{substreams}$, $[b_{0,do}..b_{N_{substreams}-1,do}]$ are split into two words of width $\eta_{MOD} = N_{substreams} / 2$, $[y_{0,2do}..y_{\eta_{MOD}-1,2do}]$ and $[y_{0,2do+1}..y_{\eta_{MOD}-1,2do+1}]$, as described in clause 6.2.1.

8.4.4.2 Mapping onto QAM constellations

The cell words of each coded L1 signalling part 2, $[y_{0,q}..y_{\eta_{MOD}-1,q}]$ are mapped into constellations f_q according to clause 6.2.2, where q is the index of the cells within each bit-interleaved LDPC codeword. For each coded L1 signalling part 2, $0 \leq q < N_{MOD_per_Block}$.

8.5 Time interleaving of L1 signalling part 2 data

The purpose of time interleaving of the L1-part 2 data is to make L1-part2 data transmission more robust than the payload data, especially when time interleaving is applied to Data Slice. Time interleaving of L1-part2 data is identical to that of Data Slice except that pilot and reserved tone positions in a preamble are completely excluded in time interleaving process.

The Time Interleaver (TI) shall operate at L1-part2 data level before the L1 XFECFrame with L1 header is repeated to fill a L1 block symbol bandwidth. The time interleaving and L1 block building with different interleaving parameters are depicted in figure 28.

The L1_TI_MODE indicates the depth of L1-part2 data time interleaving and signalled in L1 header signalling. L1_TI_MODE = "00" means no time interleaving is applied for L1-part2 data. When L1_TI_MODE = "01" (best-fit), the time interleaving depth is the minimum number of OFDM Symbols necessary for carrying a L1 block, or $N_{L1part2_FEC_Block}$ (see clause 8.4.2 for more details of segmentation of L1-part2 data). Otherwise, the time interleaving depth is explicitly signalled and the depth is 4 OFDM Symbols when L1_TI_MODE = "10" as shown in figure 28.

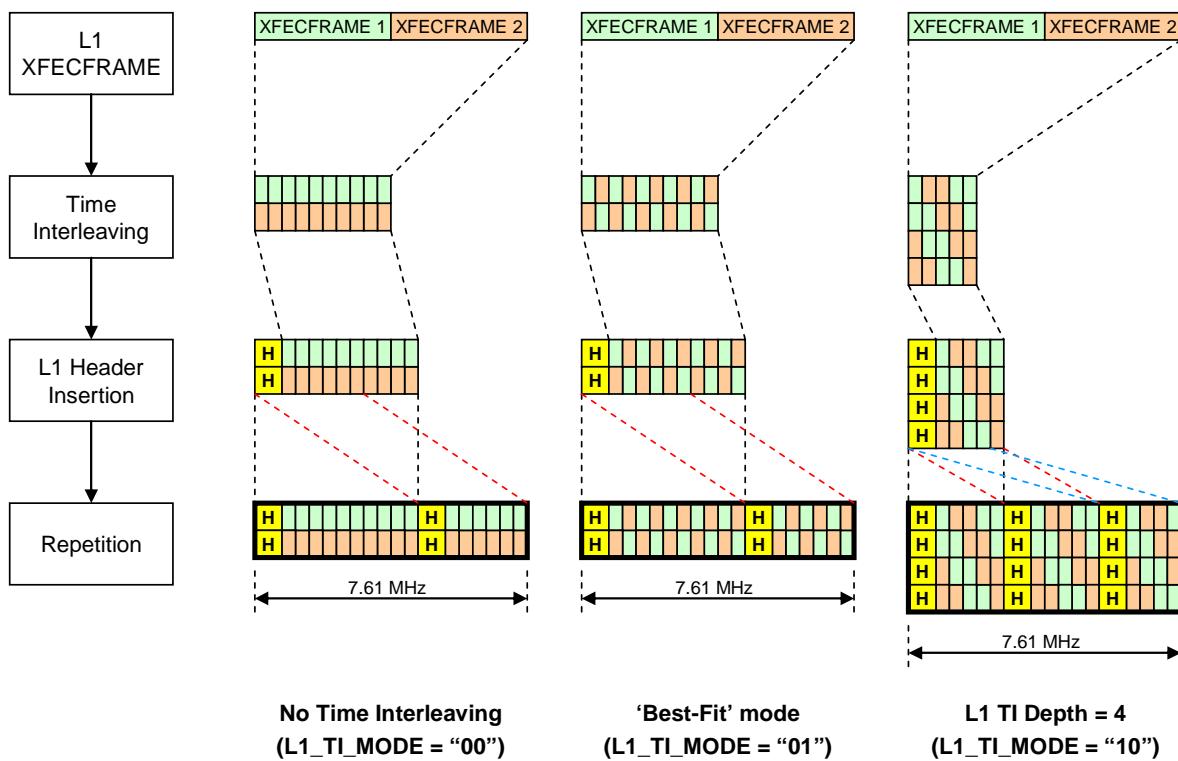

Figure 28: Time interleaving of L1-part2 data

All L1-part2 Data Cells after constellation mapping are grouped into one L1 TI block. As a result, there exists one L1 TI block per C2 Frame. The length of time interleaving period T_P is calculated as:

$$T_P = T_S \times N_{L1_TI_DEPTH},$$

where T_S is a total OFDM Symbol duration and $N_{L1_TI_DEPTH}$ is the time interleaving depth determined by L1_TI_MODE signalled in L1 header signalling.

The TI shall be a twisted row-column block interleaver like as in the Data Slice. The number of rows N_r of a TI memory is equal to $N_{LI_TI_DEPTH}$ and the number of columns N_c is calculated as:

$$N_c = N_{MOD_Total} / N_{LI_TI_DEPTH},$$

where N_{MOD_Total} is the total number of the L1-part2 Data Cells. Note that $N_{LI_TI_DEPTH}$ should be equal or larger than minimum number of OFDM Symbols required for carrying the L1 block, $N_{LIpart2_FEC_Block}$. Details of required number of bits and cells for carrying L1-part2 data is described in clause 8.4.2.

The input L1-part2 Data Cells are serially written into the TI memory in a diagonal direction, and serially read out row-wise as shown in figure 29.

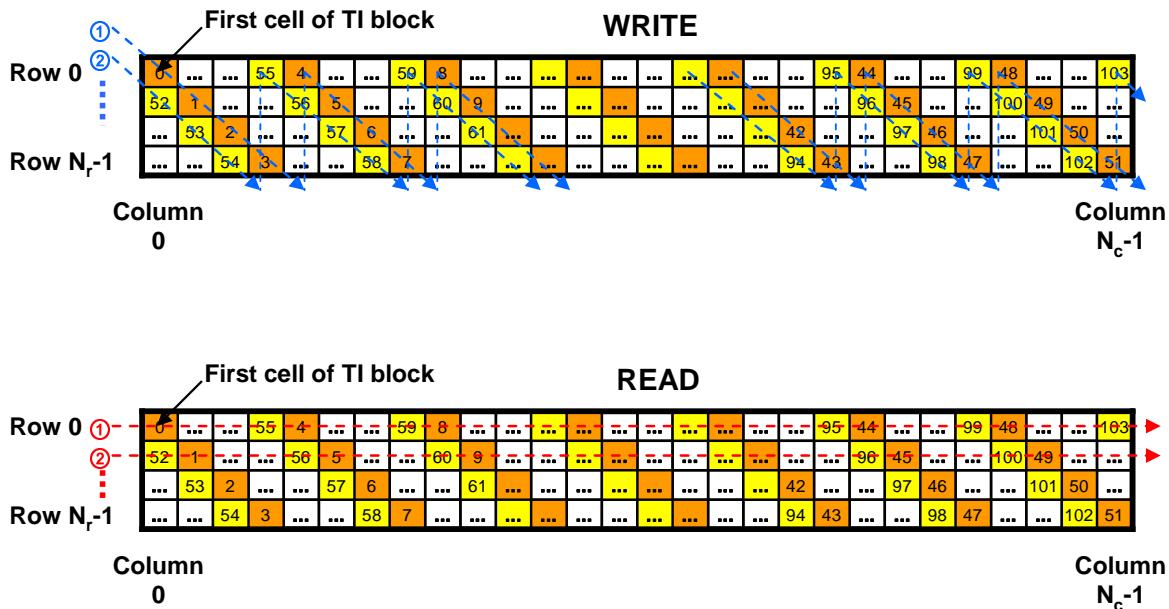

Figure 29: Time interleaving of L1 data ($N_{MOD_TOTAL}=208$, $N_{LI_TI_DEPTH}=4$)

Assuming d_i ($i = 0, \dots, N_{MOD_Total}-1$) as the L1-part2 Data Cells input to the time interleaver, the column index C_i , the row index R_i and associated twisting parameter T_{C_i} to store d_i is calculated as:

$$\begin{aligned} C_i &= i \bmod N_c \\ T_{C_i} &= C_i \bmod N_r \\ R_i &= (T_{C_i} + (i \bmod N_c)) \bmod N_r. \end{aligned}$$

Every cell position in the TI memory is uniquely defined by a coordinate (R_i, C_i) . The L1-part2 Data Cells d_i are written in positions (R_i, C_i) :

```
for (i = 0; i < NMOD_Total; i = i + 1) {
    GENERATE (Ri, Ci);
    WRITE di to (Ri, Ci);
}
```

Note that the time interleaving structure shall not be changed after frame building although neither pilot nor reserved tone position is considered in L1-part2 data time interleaving process, which is different from the case of Data Slice.

9 Frame Builder

This clause defines the frame builder functions that always apply for a C2 System. The function of the frame builder is to assemble the cells of the Preamble Symbols(s) as well as the cells produced for each of the Data Slices into arrays of active OFDM Cells corresponding to the preamble structure and each of the Data Slices and OFDM Symbols which make up the overall frame structure. The frame builder operates according to the dynamic information produced by the scheduler (see clause 5.2.1) and the configuration of the frame structure.

9.1 C2 Frame structure

The C2 Frame structure is shown in figure 30. The C2 Frame structure comprises L_P Preamble Symbols ($L_P \geq 1$) followed by L_{data} Data Symbols. The Preamble Symbols are divided in frequency direction into L1 block symbols of same bandwidth (3 408 subcarriers or approximately 7,61 MHz). The Data Slices have an arbitrary bandwidth as a multiple of the pilot pattern specific granularity but shall not exceed the L1 block symbol bandwidth. Frequency Notches can be inserted into the C2 signal across a C2 Frame. The insertion of frequency Notches is described in clauses 9.3.5 and 9.4.1.3.

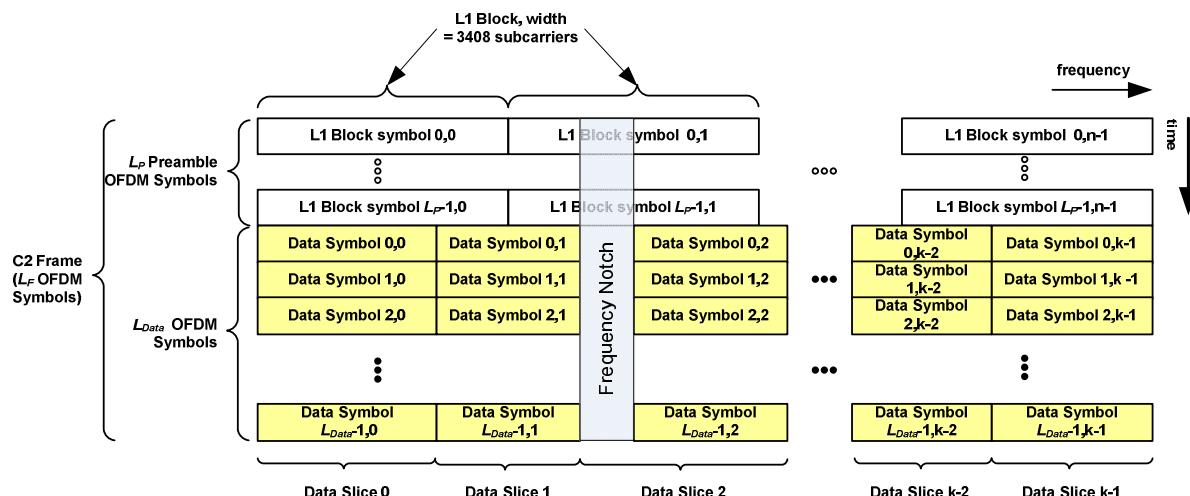

Figure 30: The C2 Frame structure: the C2 Frame starts with at least one Preamble Symbol (L_P) followed by L Data Symbols

The special properties of the Preamble Symbols are explained in clause 9.3. The L1 block symbols of the Preamble Symbol(s) allow reliable time and frequency synchronization and also carry the L1 signalling data part 2. The L1 signalling part 2 data to be carried is described in clause 8.3, its modulation, error correction and coding and the mapping of this data onto the L1 block symbols is described in clause 8.4.

9.1.1 Duration of the C2 Frame

The beginning of the first Preamble Symbol marks the beginning of the C2 Frame. The data part of the C2 Frame consists of $L_{data} = 448$ symbols (approx. 203,8 ms for $GI = 1/64$ or 202,2 ms for $GI = 1/128$, $T_U = 448 \mu s$).

The number of Preamble Symbols L_P can be derived from the length information at the beginning of each L1 signalling part 2 block.

The C2 Frame duration is therefore given by:

$$T_F = (L_P + L_{data}) \times T_s,$$

where T_s is the total OFDM Symbol duration.

9.2 Pilot Reference Sequence

9.2.1 Data Scrambling Sequence

The reference sequence described below is used to scramble the preamble data and is used to generate the pilot's modulation.

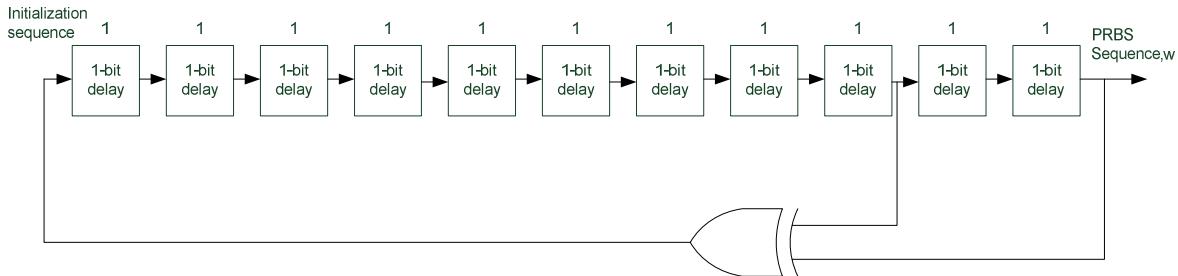

Figure 31: Generation of PRBS sequence

The PRBS sequence, w_i is generated according to figure 31, where w_i is the i-th output value of the PRBS generator. Its polynomial for the PRBS generator shall be:

$$X^{11} + X^2 + 1$$

The shift register is initialized with all '1's so that the sequence begins with $w_0, w_1, w_2 \dots = 1,1,1,1,1,1,1,1,1,1,0,0\dots$

9.2.2 Pilot Scrambling Sequence

The pilots shall carry a unique synchronization sequence w_k^P , where k is the absolute OFDM carrier index.

The sequence is defined as:

$$w_k^P = w_k \oplus w_i' \text{ with } i = (k \bmod K_{L1}) / D_P$$

Where: k is the OFDM carrier index, w_i' is the i-th output of the PRBS generator defined below, w_k is the k-th output of the reference sequence defined in clause 9.2.1 and $D_P = 6$ is the separation of the preamble pilots. Please note that i is always an integer value, as the reference sequence is only defined for pilot positions (i.e. $k \bmod D_P = 0$).

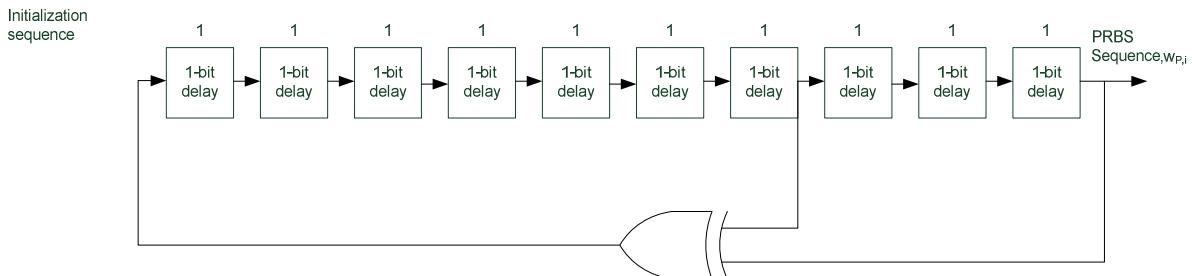

Figure 32: Definition of pilot modulation

The corresponding sequence w_i' is generated by the PRBS defined in figure 32. Its polynomial shall be:

$$X^{10} + X^3 + 1$$

The register is initialized to all '1's and the sequence begins $w_0', w_1', w_2' \dots = 1,1,1,1,1,1,1,1,1,0,0\dots$

9.2.3 Pilot Reference Sequence

The preamble pilots shall be differentially BPSK modulated against each other. Therefore, the pilot reference sequence is generated by differential modulation of the pilot scrambling sequence, which is achieved by an XOR operation.

The pilot reference sequence for each OFDM pilot at position k is therefore given by:

$$r_k = \begin{cases} w_k^P & \text{if } k \bmod K_{L1} = 0 \\ r_{k-6} \oplus w_k^P & \text{otherwise} \end{cases}$$

where r_k only has to be defined if k is multiple of 6.

9.3 Preamble Symbol

9.3.1 Preamble Symbol overview

At the beginning of every frame a Preamble Symbol shall be sent. The Preamble Symbol is constructed with L_p OFDM Symbols, while the Preamble Symbol shares the same OFDM parameters as the normal Data Symbols. In the frequency domain, the preamble is subdivided into L1 Signalling Blocks. Each L1 Signalling Block contains all Layer 1-part 2 information as defined in clause 8.

The definition of the OFDM Cell $c_{m,l,k}^P$ is calculated generically for $k = 0, \dots, \infty$. However, this definition is for simplicity only and only the OFDM carriers $K_{\min} \leq k \leq K_{\max}$ have to be calculated and are transmitted, where K_{\min} is the lowest frequency used by the C2 Signal and K_{\max} is the highest frequency used by the C2 Signal. This structure is also depicted in figure 33. The carriers outside the actual signal bandwidth are referred to as virtual signalling data. Their purpose is the clarification of the cyclic frequency structure of the signalling data.

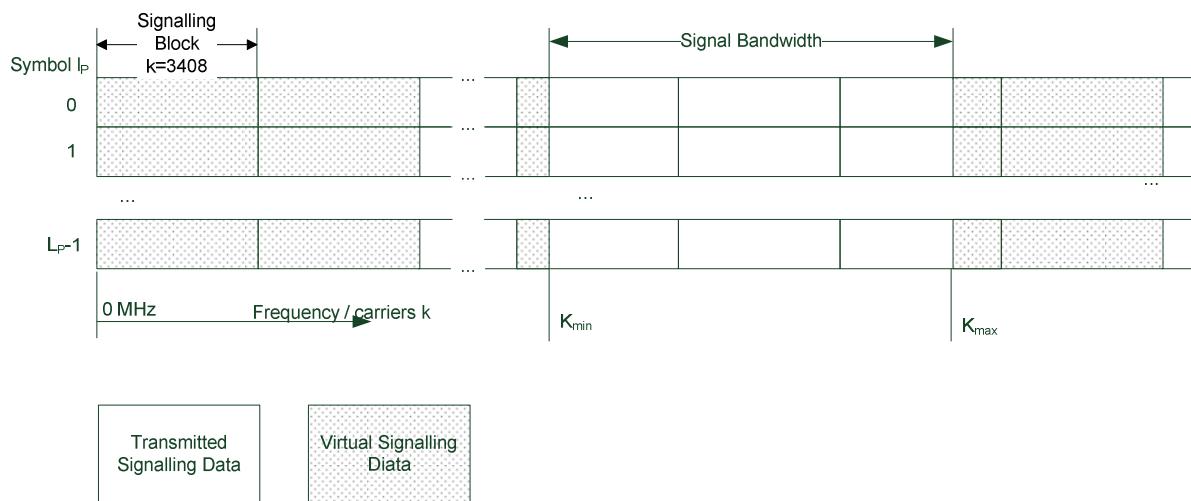

Figure 33: Preamble symbol structure in the frequency domain

9.3.2 Frequency Interleaving

The purpose of the preamble frequency interleaver is the separation of neighbouring data cells and to avoid error bursts caused by narrow band interferers or frequency selectivity. Therefore, the same frequency interleaver as for the Data Slices shall be used (see clause 9.4.5), which works on the $N_{L1}=2\ 840$ data cells of each L1 Block.

The interleaved vector $A_{l_p}^P = (a_{l_p,0}^P, a_{l_p,1}^P, \dots, a_{l_p,N_p-1}^P)$ is defined by:

$$a_{l_p,q}^P = x_{l_p, H_0(q)} \text{ for even symbols in the preamble } (l_p \bmod 2 = 0) \text{ for } q = 0, 1, \dots, N_{L1} - 1$$

$$a_{l_p,q}^P = x_{l_p, H_1(q)} \text{ for odd symbols in the preamble } (l_p \bmod 2 = 1) \text{ for } q = 0, 1, \dots, N_{L1} - 1$$

with $N_{L1} = 2840$.

9.3.3 Pilot insertion

The pilots of each Signalling Block are uniquely defined and allow for the time and frequency synchronization to the preamble. Unlike the normal pilots, the pilots within the preamble are transmitted at the same power level as the data, i.e. they are not boosted. The pilots are differentially BPSK modulated against each other, giving a receiver the possibility to synchronize on this differentially encoded reference information.

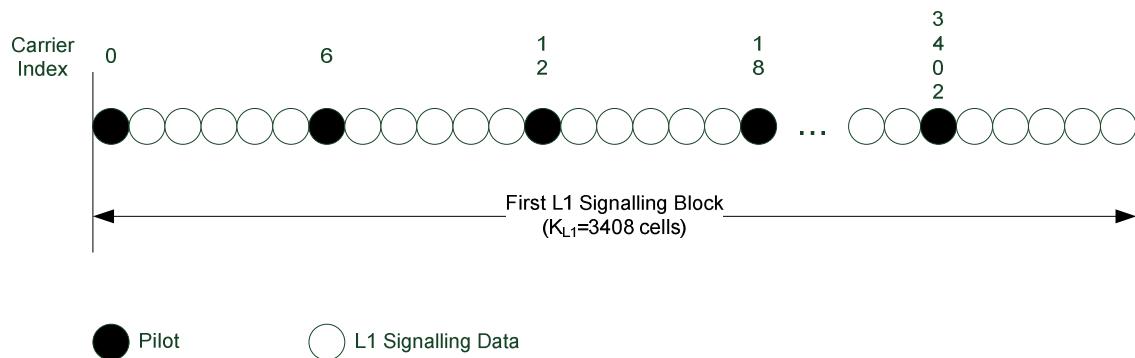

Figure 34: L1 Block signalling

9.3.3.1 Locations of the preamble pilots

A given OFDM carrier k of the Preamble Symbol is a pilot if the following equation is fulfilled:

$$k \bmod D_p = 0$$

Where: k is the OFDM carrier index and $D_p = 6$ is the separation of the preamble pilots.

9.3.3.2 Amplitude and modulation of the preamble pilots

The pilots shall be modulated as:

$$\operatorname{Re}\{c_{m,l_p,k}^P\} = A_{PP} \cdot 2(1/2 - r_k)$$

$$\operatorname{Im}\{c_{m,l_p,k}^P\} = 0$$

Where A_{PP} is the amplitude of the preamble pilots, r_k is the pilot reference sequence as defined in clause 9.2.3, m is the C2 Frame, l_p is the Preamble Symbol number and k is the absolute carrier index.

The amplitude of preamble pilots (A_{PP}) is fixed to $A_{PP}=6/5$ in case of 1/128 Guard Interval and fixed to $A_{PP}=4/3$ in case of 1/64 Guard Interval.

9.3.4 Mapping and scrambling of the signalling data

The OFDM Cells that are not occupied by pilots shall carry signalling data. As the signalling data is cyclic in the frequency domain, it shall be scrambled. The content of each data preamble OFDM Cell k is defined as:

$$\begin{aligned} \operatorname{Re}\left\{c_{m,l_p,k}^P\right\} &= \operatorname{Re}\left\{a_{l_p,q}^P\right\} \cdot (-1)^{w_k} \\ \operatorname{Im}\left\{c_{m,l_p,k}^P\right\} &= \operatorname{Im}\left\{a_{l_p,q}^P\right\} \cdot (-1)^{w_k} \end{aligned} \text{ with } q = (k \bmod K_{L1}) - \lceil (k \bmod K_{L1}) / 6 \rceil$$

Where $a_{l_p,q}^P$ is the output of the frequency interleaver of OFDM Symbol l_p at index q , w_k is the k-th output of the reference sequence defined in clause 9.2.1 and $K_{L1} = 3408$ is the number of OFDM carriers per L1 Signalling Block.

Since Data Slices are typically not aligned to L1 signalling blocks the receiver tuning window typically contains parts of different L1 signalling blocks. The re-ordering of the included sub-carriers to retrieve the L1 block in the frequency domain (i.e. after FFT on receiver side) is shown in figure 35.

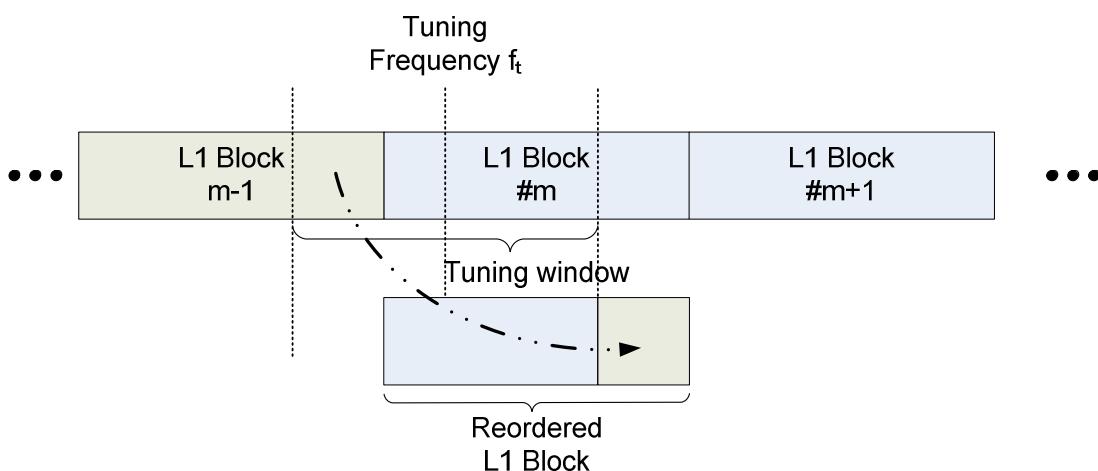

Figure 35: Retrieving a complete L1 block out of two partial L1 blocks

Depending on the receiver tuning frequency f_t , (given as actual tuning position as OFDM subcarrier mod K_{L1}) the reordered L1 Block (including pilots) is described as follows (3 584 subcarrier receiver example):

- $f_t \bmod K_{L1} < 1704$: L1_subcarriers = $[L1_m(f_t \dots (f_t + 1704)), L1_{m-1}(f_t + K_{L1} - 1703) \dots K_{L1})]$
- $f_t \bmod K_{L1} \geq 1704$: L1_subcarriers = $[L1_m((f_t - 1703) \dots K_{L1}), L1_{m+1}(1 \dots (f_t - K_{L1} + 1704))]$

With m as the index of the L1 block.

9.3.5 Notches within Preamble Symbols

Equivalent to Data Slices Preamble Symbols may contain Notches. The cells within preamble Notches shall not carry any transmit power. Preamble Notches always coincide with Data Slice Notches, i.e. the same OFDM sub-carriers are omitted. Notches can be applied to Preamble Symbols in 2 different ways.

9.3.5.1 Narrowband Notches

Narrowband Notches have a bandwidth below 48 OFDM subcarriers. The Data Slices bandwidth is a multiple of the guard interval granularity (i.e. 11, 23, 35, 47 subcarriers for GI = 1/64 or 23, 47 subcarriers for GI = 1/128).

The lack of L1 signalling in narrowband Notches is compensated by the preamble FEC. Only one narrowband Notch shall be allowed at any tuning position of 3408 OFDM subcarriers (i.e. 7,61 MHz for the 8 MHz mode and 5,71 MHz for the 6 MHz mode) bandwidth.

9.3.5.2 Broadband Notches

Broadband Notches have a bandwidth higher than 47 subcarriers. For Data Slice decoding the receiver tuner shall not tune to a region with a broadband Notch since a reliable L1 decoding cannot be guaranteed (missing L1 blocks cannot be recovered by the preamble FEC in every case).

Broadband Notches shall not be inserted in the C2 System unless at least one neighboured continuous L1 signalling block region above 3 408 subcarriers is available. During initial acquisition to a C2 System this allows the receiver to recognize the broadband Notch and to retune to a frequency range with consistent L1 signalling data.

Broadband Notches shall always be located between different Data Slices.

In case the set of subcarriers of C2 system neighboured to a broadband notch is below 3 408 subcarriers (i.e. L1 blocks can't be decoded in a reliable way), all Data Slices within this set of subcarriers shall use the Data Slice Type 2 and be configured to 'fixed' (i.e. DSLICE_CONST_CONF flag in L1 part 2 signalling is set to 1).

In any case the minimum set of subcarriers of a C2 System neighboured to a broadband notch is 841 subcarriers, ensuring that at least 5 continual pilots are available in the related frequency band for proper signal processing in receivers.

9.4 Data Slice generation

Data Slices can be treated as separate channels and no interleaving is performed between different ones. Each Data Slice is identified by a start OFDM carrier $K_{DS,\min}$ and an end OFDM carrier $K_{DS,\max}$, whereby $K_{DS,\min} \geq K_{\min}$ and $K_{DS,\max} < K_{\max}$. Data Slices shall only start and end at scattered pilots positions and end next to a scattered pilot position. Additionally, Data Slices shall not overlap each other.

9.4.1 Location of Data Slices

9.4.1.1 Start and end OFDM carrier of Data Slices

The start and the end frequency of the Data Slices is signalled in the Layer 1 Signalling by means of the START_FREQUENCY, the DSLICE_TUNE_POS, the DSLICE_OFFSET_LEFT and DSLICE_OFFSET_RIGHT values. While the START_FREQUENCY and the DSLICE_TUNE_POS are quasi static between different C2 Frames, the other two values may change every frame, depending on the chosen mode. As the Data Slices shall only start at scattered pilots positions and end next to them, the signalling depends on the value D_X (which depends on the Guard Interval size). Furthermore, the value of START_FREQUENCY shall be a multiple of D_X as well.

Thus, the start frequency and end carrier of a Data Slice shall be:

$$K_{DS,\min} = (DSLICE_TUNING_POS + DSLICE_OFFSET_LEFT) \cdot D_X + START_FREQUENCY$$

$$K_{DS,\max} = (DSLICE_TUNING_POS + DSLICE_OFFSET_RIGHT) \cdot D_X + START_FREQUENCY - 1$$

9.4.1.2 Maximum width of Data Slices

The width of each Data Slice shall not exceed 3 408 OFDM carriers (7,61 MHz for $T_U = 448 \mu s$), i.e.:

$$K_{DS,\max} - K_{DS,\min} < 3408$$

If the width of a Data Slice exceeds 3 408 OFDM carriers, the receiver shall ignore the Data Slice, i.e. treat it as not present.

9.4.1.3 Minimum width of Data Slices

The Layer 1 signalling may indicate Data Slices without any payload capacity. Such Data Slices may be used if no payload data has to be transmitted. These Data Slices shall be signalled by:

$$\text{DSLICE_OFFSET_LEFT} = \text{DSLICE_OFFSET_RIGHT}$$

No Data Slices with negative width shall be signalled. If Data Slices with negative width are received, these Data Slices shall be ignored by the receiver.

If DSLICE_TYPE is '0' and the Data Slice has a width > 0 , the Data Slice shall be able to transmit at least one complete Data Slice Packet.

9.4.1.4 Notches within Data Slices

Data Slices may contain Notches. The cells within these Notches shall not carry any transmit power. The start and the end carrier of each Notch are indicated within the corresponding Layer 1 signalling. Notches always start and end next to scattered pilot positions.

The start carrier and end carrier of each Notch shall be defined as:

$$K_{N,\min} = \text{NOTCH_START} \cdot D_x + \text{START_FREQUENCY} + 1$$

$$K_{N,\max} = (\text{NOTCH_START} + \text{NOTCH_WIDTH}) \cdot D_x + \text{START_FREQUENCY} - 1$$

where D_x is the guard interval dependent pilots repartition. Notches having a NOTCH_WIDTH of 0 shall be ignored by the receiver.

9.4.2 Number of payload cells in Data Slice

The number of payload cells per Data Slice per OFDM Symbol N_{DS} equals $(K_{DS,\max} - K_{DS,\min} + 1)$ minus the number of continual pilots, scattered pilots, reserved tones and cells that are located in Notches.

Please note that the number of payload cells in a Data Slice may vary between different OFDM Symbols in one C2 Frame.

9.4.3 Mapping of the Data Slice Packets

The Data Slice Packets shall be mapped onto the N_{DS} Data Cells per OFDM Symbol. Data Cells within a Data Slice are cells, which are not pilots, reserved tones or Notches. The Data Slice Packet data $g_0, \dots, g_{N_{DS}-1}$ shall be mapped onto the Data Cells $a_{m,l,k}$ of the OFDM Symbol in an increasing value of the carrier index k within the range:

$$K_{DS,\min} \leq k \leq K_{DS,\max} .$$

If the data of one Data Slice Packet exceeds the length of a C2 Frame, the data shall cross seamlessly into the next C2 Frame. If a Data Slice was not present in the previous C2 Frame (a Data Slice of width 0 was present), the Data Slice Packet data shall be mapped to the first available Data Cell of the Data Slice.

For $\text{DSLICE_TYPE}='0'$ the start of the first complete Data Slice Packet shall be signalled within the PLP_START value of the Layer 1 signalling. If the Data Slice has zero width, the PLP_START shall be set to zero.

If no payload data is to be transmitted for $\text{DATA_SLICE_TYPE}'1'$, dummy Data Slice Packets shall be transmitted instead (see clause 7.2).

9.4.4 Time Interleaving

The time interleaver (TI) shall operate at Data Slice level. The parameters of time interleaving may be different for different Data Slices within a C2 System, while it is the same for all PLPs within a Data Slice. The exact number and positions of all pilots and reserved tones within each Data Slice shall be known to the TI prior to frame building.

The Data Cells from a Data Slice builder for each Data Slice shall be grouped into TI blocks. The start and/or end of Data Slice Packets of each PLP constituting the Data Slice may not be aligned with those of TI blocks. Each TI block within the Data Slice shall contain $N_{DSLICE_TI_DATA_CELL}$ payload Data Cells carried by $N_{DSLICE_TI_DEPTH}$ Data Symbols. $N_{DSLICE_TI_DEPTH}$ is known from $DSLICE_TI_DEPTH$ signalled in L1 signalling part2 (see clause 8.3).

$N_{DSLICE_TI_DATA_CELL}$ is calculated as:

$$N_{DSLICE_TI_DATA_CELL} = \sum_{l \in TI\ block} N_{DS}^l$$

where N_{DS}^l is the number of payload cells of l -th Data Symbol of the TI block, which is described in clause 9.4.2 in more detail. Every TI block of the Data Slice shall have the same number of payload cells.

The length of time interleaving period T_P is defined as:

$$T_P = T_S \times N_{DSLICE_TI_DEPTH},$$

where T_S is a total OFDM Symbol duration.

Simple and typical TI memory space (one per Data Slice) is identical to the space of $N_{DSLICE_TI_DEPTH}$ Data Symbols within the Data Slice. In other words, the TI memory space includes the positions of all pilot and reserved tone cells as well as $N_{DSLICE_TI_DATA_CELL}$ Data Cells. The pilot and reserved tone cell positions within TI memory may be filled with dummy zeros. Notch bands in the Data Slice may be discarded from the TI memory.

The TI shall store in the TI memories the Data Cells from the output of Data Slice builder. As the number and position of all pilots and reserved tones are previously known to the TI, the Data Cells should not be stored in pilot or reserved tone positions. Reserved pilot and reserved tone positions in the TI memory guarantees the time interleaving structure of Data Cells (shown in figure 37) are unchanged after frame building.

Typically, the time interleaver will also act as a buffer for Data Slice cells prior to the process of frame building. This can be achieved by means of two memory banks for each Data Slice. The first TI block is written to the first bank. The second TI block is written to the second bank whilst the first bank is being read from and so on, see figure 36.

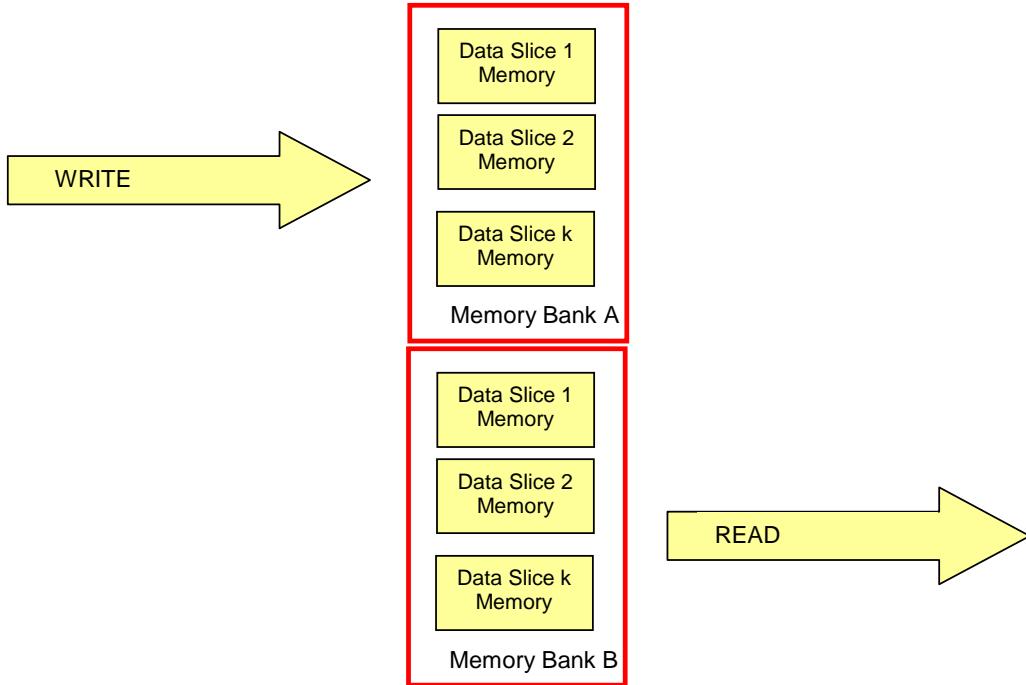

Figure 36: Example of operation of time interleaver memory banks

The TI shall be a twisted row-column block interleaver: the number of rows N_r in the interleaver is equal to the time interleaving depth $N_{DSLICE_TI_DEPTH}$ and the number of columns N_c to Data Slice width N_{DSLICE_WIDTH} . The Data Slice width is identified by:

$$N_{DSLICE_WIDTH} = K_{DS,max} - K_{DS,min},$$

where $K_{DS,max}$ and $K_{DS,min}$ is the start and end OFDM Cell index of the Data Slice respectively. More details of Data Slice configuration is described in clause 9.4.1.1. The input cells are serially written into the interleaver memory in a diagonal direction, and serially read out row-wise as shown in figure 37.

Assuming the index i ranging from 0 to $(N_{DSLICE_TI_CELL}-1)$, where $N_{DSLICE_TI_CELL}$ is the total number of cells within $N_{DSLICE_TI_DEPTH}$ Data Symbols of the Data Slice and calculated as:

$$N_{DSLICE_TI_CELL} = N_{DSLICE_TI_DEPTH} \times N_{DSLICE_WIDTH}.$$

The column index C_i , the row index R_i and associated twisting parameter T_{Ci} is calculated as:

$$\begin{aligned} C_i &= i \bmod N_c \\ T_{C_i} &= C_i \bmod N_r \\ R_i &= (T_{C_i} + (i \bmod N_c)) \bmod N_r. \end{aligned}$$

Then, every cell positions in the TI memory is uniquely defined by a coordinate (R_i, C_i) . The input Data Cells d_k ($k = 0, \dots, N_{DSLICE_TI_DATA_CELL}-1$) are written in positions (R_i, C_i) ($i = 0, \dots, N_{DSLICE_TI_CELL}-1$) within the TI memory only if the positions are assigned for payload Data Cells:

```

 $k = 0;$ 
 $for (i = 0; i < N_{DSLICE\_TI\_CELL}; i = i + 1) \{$ 
     $GENERATE (R_i, C_i);$ 
     $if (R_i, C_i) = data\ cell\ position \{$ 
         $WRITE d_k to (R_i, C_i);$ 
         $k = k + 1;$ 
     $\}$ 
 $\}$ 

```

Note that the TI outputs only Data Cells from the TI memory excluding dummy pilot cells and reserved tones. As a result, the input and output Data Cell rates are unchanged after time interleaving.

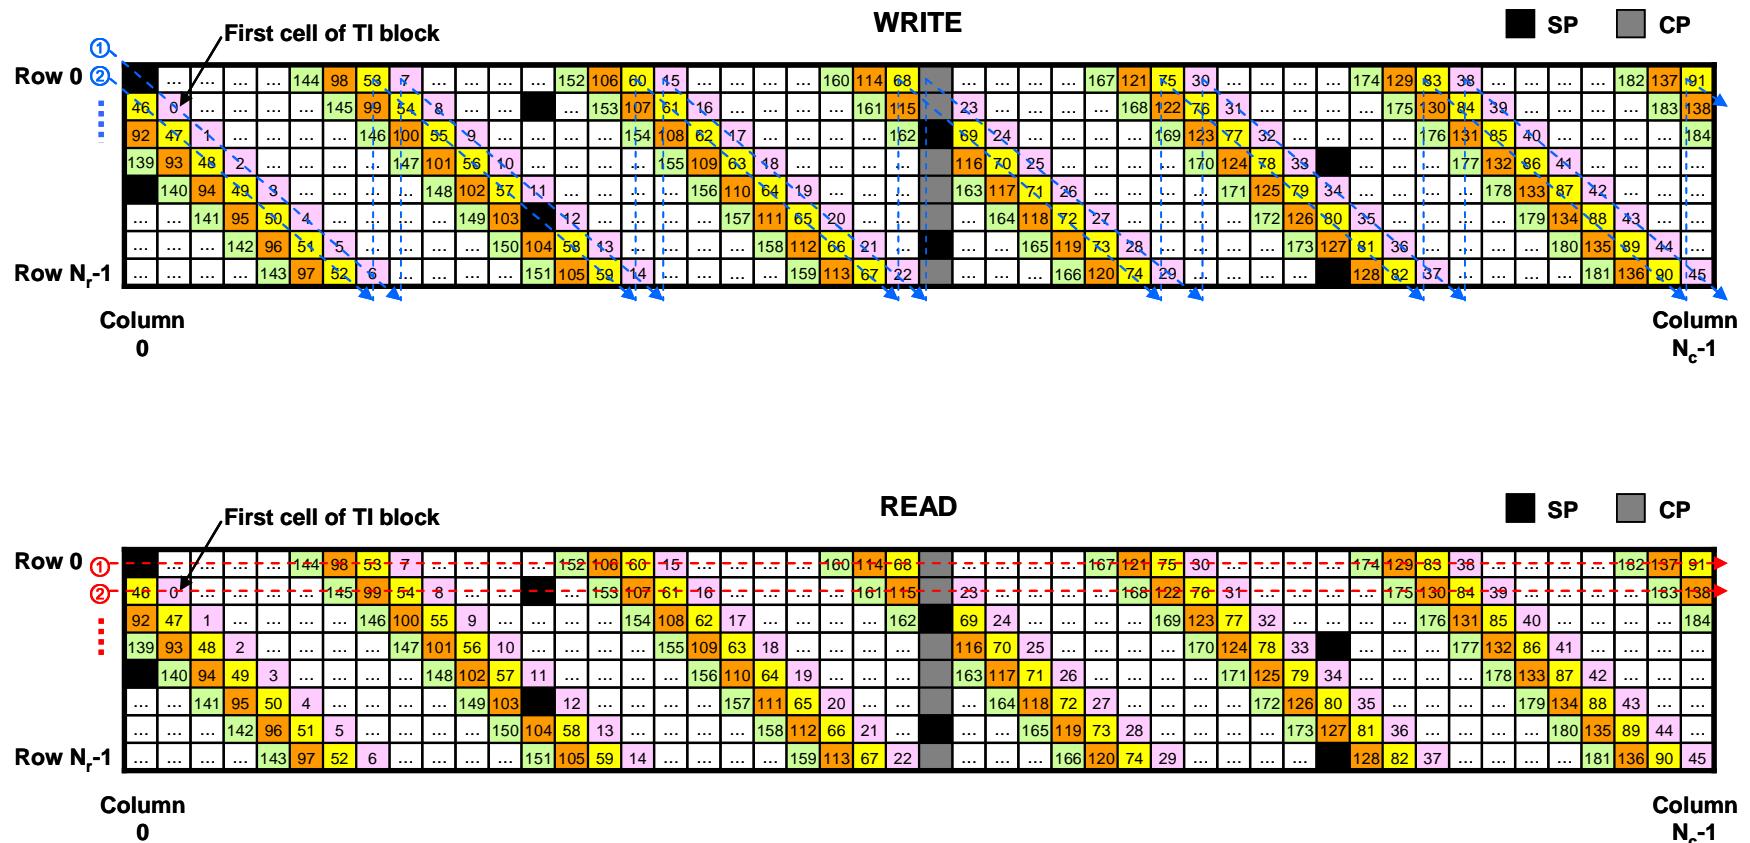

Figure 37: Time interleaver ($D_x=12$, GI=1/64, $N_r=8$, $N_c=48$, DSLICE_WIDTH=4)

9.4.5 Frequency Interleaving

The frequency interleaver operates on the Data Cells of one OFDM Symbol that comprise the slice of cells allocated to a given Data Slice. Its purpose is to map the Data Cells of this slice from the frame builder onto the N_{data} data carriers allocated for the given Data Slice in each OFDM Symbol.

For Data Slice n , the frequency interleaver shall process the Data Cells $X_{m,l} = (x_{m,l,0}, x_{m,l,1}, \dots, x_{m,l,N_{\text{data}}(n)-1})$ of the OFDM Symbol l of C2 Frame m from the frame builder.

The parameter M_{max} is defined as 4 096, i.e. the smallest power of 2 higher than the maximum Data Slice width of 3 408 OFDM Cells.

For Data Slice n with $N_{\text{data}}(n)$ data carriers in OFDM symbol l of M_{max} sub-carriers the interleaved vector $A_{m,l} = (a_{m,l,0}, a_{m,l,1}, a_{m,l,2} \dots a_{m,l,N_{\text{data}}(n)-1})$ is defined by:

$$a_{m,l,q} = x_{m,l,H_0(q)} \text{ for even symbols of the frame } (l \bmod 2 = 0) \text{ for } q = 0, \dots, N_{\text{data}}(n)-1$$

$$a_{m,l,q} = x_{m,l,H_1(q)} \text{ for odd symbols of the frame } (l \bmod 2 = 1) \text{ for } q = 0, \dots, N_{\text{data}}(n)-1$$

$H_0(q)$ and $H_1(q)$ are permutation function based on the sequence R'_i defined by the following.

An $(N_r - 1)$ bit binary word R'_i is defined, with $N_r = \log_2 M_{\text{max}}$, where R'_i takes the following values:

$$i = 0,1: \quad R'_i [N_r-2, N_r-3, \dots, 1,0] = 0,0, \dots, 0,0$$

$$i = 2: \quad R'_i [N_r-2, N_r-3, \dots, 1,0] = 0,0, \dots, 0,1$$

$$2 < i < M_{\text{max}}: \quad \{ \quad R'_i [N_r-3, N_r-4, \dots, 1,0] = R'_{i-1} [N_r-2, N_r-3, \dots, 2,1];$$

$$\text{where: } N_r = 12 \text{ and } R'_i [10] = R'_{i-1} [0] \oplus R'_{i-1} [2].$$

A vector R_i is derived from the vector R'_i by the bit permutations given in table 32.

Table 32: Bit permutations for the 4K mode

R'_i bit positions	10	9	8	7	6	5	4	3	2	1	0
R_i bit positions (H_0)	7	10	5	8	1	2	4	9	0	3	6
R_i bit positions (H_1)	6	2	7	10	8	0	3	4	1	9	5

Each permutation function $H(q)$ is defined by the following algorithm:

$$q = 0;$$

$$\text{for } (i = 0; i < M_{\text{max}}; i = i + 1)$$

$$\{ H(q) = (i \bmod 2).2^{N_r-1} + \sum_{j=0}^{N_r-2} R_i(j).2^j;$$

$$\text{if } (H(q) < N_{\text{data}}(n)) \quad q = q + 1; \quad \}$$

A schematic block diagram of the algorithm used to generate the permutation function is represented in figure 38.

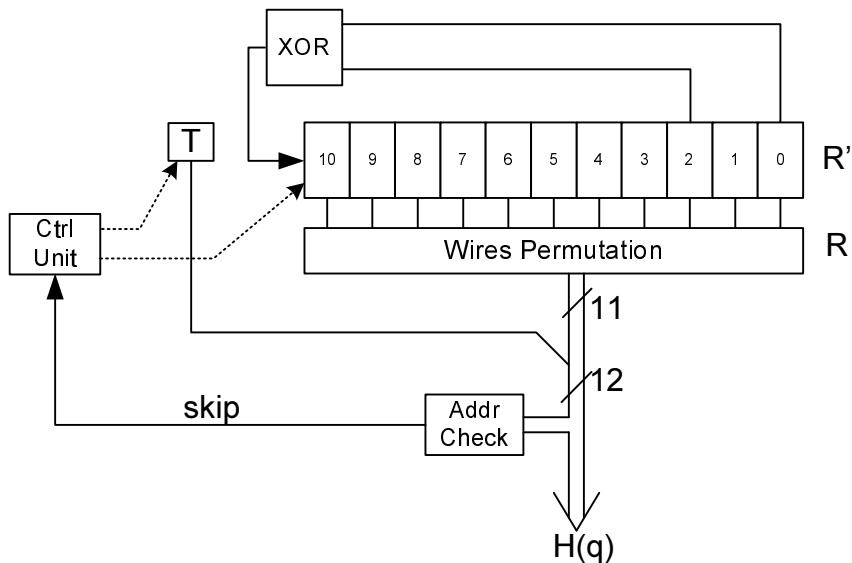

Figure 38: Frequency interleaver address generation scheme for the 4K mode OFDM

The output of the frequency interleaver for Data Slice n is the interleaved vector of Data Cells $A_{m,l} = (a_{m,l,0}, a_{m,l,1}, a_{m,l,2}, \dots, a_{m,l,N_{\text{data}}(n)-1})$ that is then allocated to Data Cells $v_{m,l,i}$ of symbol l of C2 Frame m according to:

$$v_{m,l,B(n)+i} = a_{m,l,i}$$

where $B(n)$ is the location of the first Data Cell of symbol l allocated to slice n and $i = 0, 1, 2, \dots, N_{\text{data}}(n)-1$.

9.5 Stuffing Data Slices

Within an OFDM signal Stuffing Data Slices may be transmitted. The Stuffing Data Slices shall not be signalled within the L1 signalling. Pilots and dummy carriers shall be transmitted at the same positions as in normal Data Slices.

The modulation of the cells not mapped to pilots or reserved tones shall carry a mean power value of 1. The transmitter shall ensure a random-like distribution of the modulation values.

9.6 Pilot Insertion

9.6.1 Introduction

Various cells within the OFDM frame are modulated with reference information whose transmitted value is known to the receiver. Cells containing reference information are transmitted at "boosted" power level. These cells are termed scattered, continual and edge pilots. The locations and amplitudes of these pilots are defined in clauses 9.6.2 to 9.6.4. The value of the pilot information is derived from a reference sequence, r_k which is a series of values, one for each transmitted carrier on any given symbol. The reference sequence is defined in clause 9.2.3.

The pilots can be used for frame synchronization, frequency synchronization, time synchronization, channel estimation and can also be used to follow the phase noise.

Table 33 gives an overview of the different types of pilot and the symbols in which they appear. This clause only describes pilots inserted to Data Symbols i.e. scattered, continual and edge pilots. Preamble pilots are described in clause 9.3.3.

Table 33: Presence of the various types of pilots in each type of symbol (X=present)

Symbol	PILOT TYPE			
	Scattered	Continual	Edge	Preamble
Preamble				X
Data	X	X	X	

The following clauses specify values for $c_{m,l,k}$, for certain values of m , l and k , where m and l are the C2 Frame and symbol number as previously defined, and k is the OFDM carrier index (see clause 3.2).

9.6.2 Scattered pilot insertion

Reference information, taken from the reference sequence, is transmitted in scattered pilot cells in every symbol except Preamble Symbol(s) of the C2 Frame. The locations of the scattered pilots are defined in clause 9.6.2.1, their amplitudes are defined in clause 9.6.2.2 and their modulation is defined in clause 9.6.2.3.

9.6.2.1 Locations of the scattered pilots

The locations of scattered pilots depend only upon the symbol index l , carrier index k and the GI fraction. A given carrier k of the OFDM signal on a given symbol l will be a scattered pilot if the appropriate equation below is satisfied:

$$k \bmod(D_X \cdot D_Y) = D_X(l \bmod D_Y)$$

where: D_X, D_Y are defined in table 34.

k : 0 RF origin carrier index.

l : Data Symbol index.

Table 34: Parameters defining the scattered pilot patterns

GI Fraction	Separation of pilot bearing carriers (D_X)	Number of symbols forming one scattered pilot sequence (D_Y)
1/64	12	4
1/128	24	4

The scattered pilot patterns are illustrated in annex H.

9.6.2.2 Amplitudes of the scattered pilots

The amplitudes of the scattered pilots, A_{SP} , are fixed as 7/3. This amplitude is commonly used for continual pilots and edge pilots as well.

9.6.2.3 Modulation of the scattered pilots

The phases of the scattered pilots are derived from the reference sequence given in clause 9.3.

The modulation value of the scattered pilots is given by:

$$\text{Re}\{c_{m,l,k}\} = A_{SP} 2(1/2 - r_k)$$

$$\text{Im}\{c_{m,l,k}\} = 0.$$

where A_{SP} is as defined in clause 9.6.2.2, r_k is defined in clause 9.3, m is the C2 Frame index, k is the frequency index of the carriers.

9.6.3 Continual pilot insertion

In addition to the scattered pilots described above, a number of continual pilots are inserted in every symbol of the frame except for Preamble Symbol(s). The number and location of continual pilots are the same for all GI fractions (i.e. for scattered pilot patterns).

9.6.3.1 Locations of the continual pilots

The continual pilot locations are defined within a block of $K_{L1} = 3\ 408$ carriers and this pattern is repeated to support the entire range of possible carriers. The K_{L1} carrier index block is aligned with the L1 signalling block, whose length is also K_{L1} .

The continual pilot locations within the K_{L1} carrier index block are defined in table 35. A given carrier index k of the OFDM signal will be a continual pilot if $k \bmod K_{L1}$ is matched with one of the numbers in table 34.

Table 35: Continual Pilot Carrier Indices

Indices								
96	216	306	390	450	486	780	804	
924	1 026	1 224	1 422	1 554	1 620	1 680	1 902	
1 956	2 016	2 142	2 220	2 310	2 424	2 466	2 736	
3 048	3 126	3 156	3 228	3 294	3 366			

9.6.3.2 Amplitudes of the Continual Pilots

The amplitudes of the continual pilots, A_{CP} , are fixed as $7/3$. This amplitude is commonly used for scattered pilots and edge pilots as well.

9.6.3.3 Modulation of the Continual Pilots

The phases of the continual pilots are derived from the reference sequence given in clause 9.3.

The modulation value for the continual pilots is given by:

$$\text{Re}\{c_{m,l,k}\} = 2 A_{CP} (1/2 - r_k)$$

$$\text{Im}\{c_{m,l,k}\} = 0.$$

where r_k is defined in clause 9.3.

9.6.4 Edge pilot insertion

In addition to the scattered and continual pilots, a number of edge pilots are also inserted at the 'edge' carrier locations in every symbol except Preamble Symbol(s). The number of edge pilots depends upon the number of spectrum Notches within an OFDM signal.

9.6.4.1 Locations of the edge pilots

There are two kinds of edge carrier; those carriers at the upper and lower extremes of the OFDM spectrum and those carriers either side of a spectrum Notch. The edge pilots are inserted in both cases.

The lowest frequency edge pilot of the OFDM spectrum is inserted by replacing potential data and scattered pilot carriers. On the other hand the highest frequency edge pilot of the OFDM spectrum is inserted as an extra carrier to the data carriers. This ensures that the edge pilots are on the scattered pilot bearing carriers. These pilot locations are shown in figure 39.

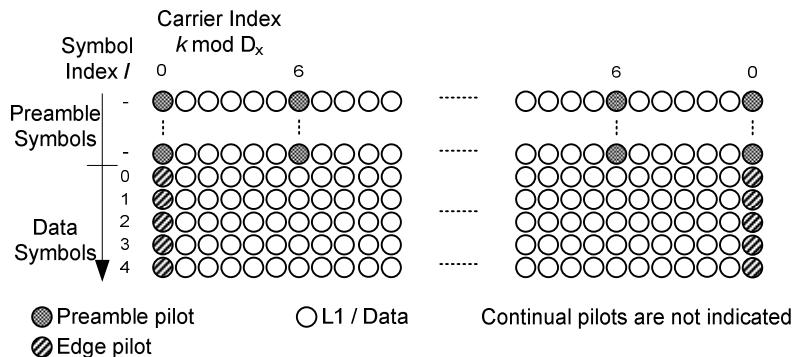

Figure 39: OFDM spectrum edge pilot locations

Edge pilots are also placed either side of spectrum Notches. The edge pilot for the lower frequency edge of a Notch is inserted at carrier index $K_{N,\min} - 1$, whereas the edge pilot for the higher frequency edge of a Notch is inserted at carrier index $K_{N,\max} + 1$. Where $K_{N,\min}$ and $K_{N,\max}$ are the start and end carrier indices for a spectrum Notch, details are defined in clause 9.4.1.3. These edge pilots will lie on scattered pilot bearing subcarriers. These pilot locations are shown in figure 40.

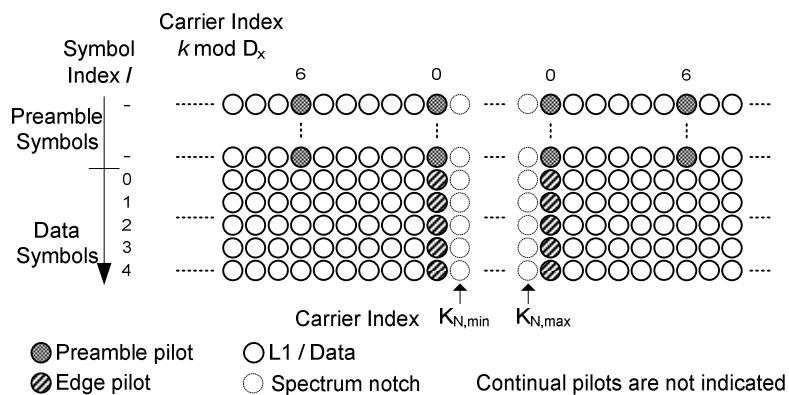

Figure 40: Spectrum Notch edge pilot locations

NOTE: The edge pilot locations are always be at integer multiples of D_x . They are scattered pilot bearing carriers.

9.6.4.2 Amplitudes of the Edge Pilots

The amplitude of the edge pilots and the scattered pilots is $7/3$.

9.6.4.3 Modulation of the Edge Pilots

The modulation of these cells is exactly the same as for the scattered pilots, as defined in clause 9.6.2.3:

$$\operatorname{Re}\{c_{m,l,k}\} = 2 A_{SP} (1/2 - r_k)$$

$$\operatorname{Im}\{c_{m,l,k}\} = 0.$$

9.7 Dummy carrier reservation

Some OFDM Cells can be reserved for varying purposes, e.g. PAPR reduction. The amplitudes of these cells can be defined freely, while their power level shall not exceed the power level of pilots within the data OFDM Symbols.

In the Data Symbols excluding Preamble Symbols, the set of carriers corresponding to carrier indices defined in table 36 or their circularly shifted set of carriers shall be reserved depending on the OFDM Symbol index of the Data Symbol, when the reserved tones are activated by a relevant L1 signalling part 2, 'RESERVED_TONES'. The amount of shift between two consecutive OFDM Symbols shall be determined by the separation of pilot bearing carriers, D_X and the number of symbols forming one scattered pilot sequence, D_Y (see table 34 in clause 9.6.2.1). Furthermore, the reserved carrier patterns are repeated at every interval of 8 blocks of $K_{L1}=3$ 408 carriers. Thus, in the Data Symbol corresponding to Data Symbol index l of a C2 Frame, the OFDM Cell is a reserved tone if:

$$[k \bmod (8 \cdot K_{L1})] - D_X(l \bmod D_Y) \in S_0 \quad 0 \leq l < L_{Data}$$

where k is the absolute carrier index, L_{data} denotes the number of Data Symbols in a C2 Frame, and S_0 is the set of carrier indices listen in table 36.

Positions of reserved carriers within Notches shall be excluded from the set of reserved carriers.

Table 36: Reserved carrier indices S_0

Reserved Carrier Indices S_0
161, 243, 296, 405, 493, 584, 697, 741, 821, 934, 1021, 1160, 1215, 1312, 1417, 1462, 1591, 1693, 1729, 1845, 1910, 1982, 2127, 2170, 2339, 2365, 2499, 2529, 2639, 2745, 2864, 2950, 2992, 3119, 3235, 3255, 3559, 3620, 3754, 3835, 3943, 3975, 4061, 4210, 4270, 4371, 4417, 4502, 4640, 4677, 4822, 4904, 5026, 5113, 5173, 5271, 5317, 5426, 5492, 5583, 5740, 5757, 5839, 5935, 6033, 6146, 6212, 6369, 6454, 6557, 6597, 6711, 6983, 7047, 7173, 7202, 7310, 7421, 7451, 7579, 7666, 7785, 7831, 7981, 8060, 8128, 8251, 8326, 8369, 8445, 8569, 8638, 8761, 8873, 8923, 9017, 9104, 9239, 9283, 9368, 9500, 9586, 9683, 9782, 9794, 9908, 9989, 10123, 10327, 10442, 10535, 10658, 10739, 10803, 10925, 11006, 11060, 11198, 11225, 11326, 11474, 11554, 11663, 11723, 11810, 11902, 11987, 12027, 12117, 12261, 12320, 12419, 12532, 12646, 12676, 12808, 12915, 12941, 13067, 13113, 13246, 13360, 13426, 13520, 13811, 13862, 13936, 14073, 14102, 14206, 14305, 14408, 14527, 14555, 14650, 14755, 14816, 14951, 15031, 15107, 15226, 15326, 15392, 15484, 15553, 15623, 15734, 15872, 15943, 16043, 16087, 16201, 16299, 16355, 16444, 16514, 16635, 16723, 16802, 16912, 17150, 17285, 17387, 17488, 17533, 17603, 17708, 17793, 17932, 18026, 18081, 18159, 18285, 18356, 18395, 18532, 18644, 18697, 18761, 18874, 18937, 19107, 19119, 19251, 19379, 19414, 19522, 19619, 19691, 19748, 19875, 19935, 20065, 20109, 20261, 20315, 20559, 20703, 20737, 20876, 20950, 21069, 21106, 21231, 21323, 21379, 21494, 21611, 21680, 21796, 21805, 21958, 22027, 22091, 22167, 22324, 22347, 22459, 22551, 22691, 22761, 22822, 22951, 22981, 23089, 23216, 23290, 23402, 23453, 23529, 23668, 23743, 24019, 24057, 24214, 24249, 24335, 24445, 24554, 24619, 24704, 24761, 24847, 24947, 25089, 25205, 25274, 25352, 25474, 25537, 25612, 25711, 25748, 25874, 25984, 26078, 26155, 26237, 26324, 26378, 26545, 26623, 26720, 26774, 26855, 26953, 27021, 27123

10 OFDM generation

The function of the OFDM generation module is to take the cells produced by the frame builder, as frequency domain coefficients and to transform them into the frequency domain.

10.1 IFFT - OFDM Modulation

This clause specifies the OFDM structure to use for each transmission mode. The transmitted signal is organized in frames. Each frame has duration of T_F , and consists of L_F OFDM Symbols. Each symbol is constituted by a set of K_{total} carriers transmitted with a duration T_S . It is composed of two parts: a useful part with duration T_U and a guard interval with duration Δ . The guard interval consists of a cyclic continuation of the useful part, T_U , and is inserted before it. The allowed combinations of FFT size and guard interval are defined in table 38.

The symbols in a C2 Frame are numbered from 0 to L_F -1. All symbols contain data and reference information.

Since the OFDM signal comprises many separately modulated carriers, each symbol can in turn be considered to be divided into cells, each corresponding to the modulation carried on one carrier during one symbol.

The carriers are indexed by $k \in [K_{\min}; K_{\max}]$ and determined by K_{\min} and K_{\max} . The spacing between adjacent carriers is $1/T_U$ while the spacing between carriers K_{\min} and K_{\max} are determined by K_{total}/T_U .

The emitted signal is described by the following expression:

$$s(t) = \operatorname{Re} \left\{ \sum_{m=0}^{\infty} \left[\frac{1}{\sqrt{K_{\text{total}}}} \sum_{l=0}^{L_F-1} \sum_{k=K_{\min}}^{K_{\max}} c_{m,l,k} \times \psi_{m,l,k}(t) \right] \right\}$$

Where:

$$\psi_{m,l,k}(t) = \begin{cases} e^{j2\pi \frac{k}{T_U} (t - \Delta - lT_s - mT_F)} & mT_F + lT_S \leq t < mT_F + (l+1)T_S \\ 0 & \text{otherwise} \end{cases}$$

and:

k denotes the carrier number;

l denotes the OFDM Symbol number starting from 0 for the first Preamble Symbol of the frame;

m denotes the C2 Frame number;

K_{total} is the number of transmitted carriers, i.e. $K_{\text{total}} = K_{\max} - K_{\min} + 1$;

L_F total number of OFDM Symbols per frame (including the preamble);

T_S is the total symbol duration for all symbols, and $T_S = T_U + \Delta$;

T_U is the active symbol duration defined in table 38;

Δ is the duration of the guard interval, see clause 10.2;

$c_{m,l,k}$ is the complex modulation value for carrier k of the OFDM Symbol number l in C2 Frame number m ;

T_F is the duration of a frame, $T_F = L_F T_s$;

K_{\min} Carrier index of first (lowest frequency) active carrier;

K_{\max} Carrier index of last (highest frequency) active carrier.

The OFDM parameters are summarized in table 38. The values for the various time-related parameters are given in multiples of the Elementary Period T and in microseconds. The Elementary Period T is specified for each channel raster bandwidth in table 37.

Table 37: Elementary period as a function of channel raster bandwidth

Channel Raster	"6 MHz"	"8 MHz"
Elementary period T	7/48 μ s	7/64 μ s

Table 38: OFDM parameters

Parameter	"6 MHz" 1/64	"6 MHz" 1/128	"8 MHz" 1/64	"8 MHz" 1/128
Number of OFDM carriers per L1 Block K_{L1}	3 408	3 408	3 408	3 408
Bandwidth of L1 Signalling Block (see note)	<i>5,71 MHz</i>	<i>5,71 MHz</i>	<i>7,61 MHz</i>	<i>7,61 MHz</i>
Duration T_U	4 096 T	4 096 T	4 096 T	4 096 T
Duration $T_U \mu s$ (see note)	597,3	597,3	448	448
Carrier spacing $1/T_U$ (Hz) (see note)	1 674	1 674	2 232	2 232
Guard Interval Duration Δ/T_u	<i>64T</i>	<i>32T</i>	<i>64T</i>	<i>32T</i>
Guard Interval Duration $\Delta/T_u \mu s$ (see note)	9,33	4,66	7	3,5
NOTE: Numerical values in italics are approximate values.				

10.2 Guard interval insertion

Two different guard interval fractions (Δ/T_u) are defined. Further details are given in table 38 in clause 10.1.

10.3 Spectrum characteristics

The OFDM Symbols constitute a juxtaposition of equally-spaced orthogonal carriers. The amplitudes and phases of the Data Cell carriers are varying symbol by symbol according to the mapping process previously described.

The power spectral density $P_k(f)$ of each carrier at frequency:

$$f_k = \frac{k}{T_u} \text{ for } K_{\min} \leq k \leq K_{\max}$$

is defined by the following expression:

$$P_k(f) = \left[\frac{\sin \pi(f - f_k)T_s}{\pi(f - f_k)T_s} \right]^2$$

The overall power spectral density of the modulated Data Cell carriers is the sum of the power spectral densities of all these carriers. A theoretical DVB transmission signal spectrum is illustrated in figure 41. The blue curve illustrates the theoretical spectrum of a 7,61 MHz wide signal (The first used subcarrier K_{\min} is located at the relative frequency of 0 MHz). The red curve illustrates the lower frequency edge of a 445 MHz wide signal. Because the OFDM Symbol duration is larger than the inverse of the carrier spacing, the main lobe of the power spectral density of each carrier is narrower than twice the carrier spacing. Therefore the spectral density is not constant within the nominal bandwidth.

NOTE: This theoretical spectrum takes no account of the variations in power from carrier to carrier caused by the boosting of the pilot carriers.

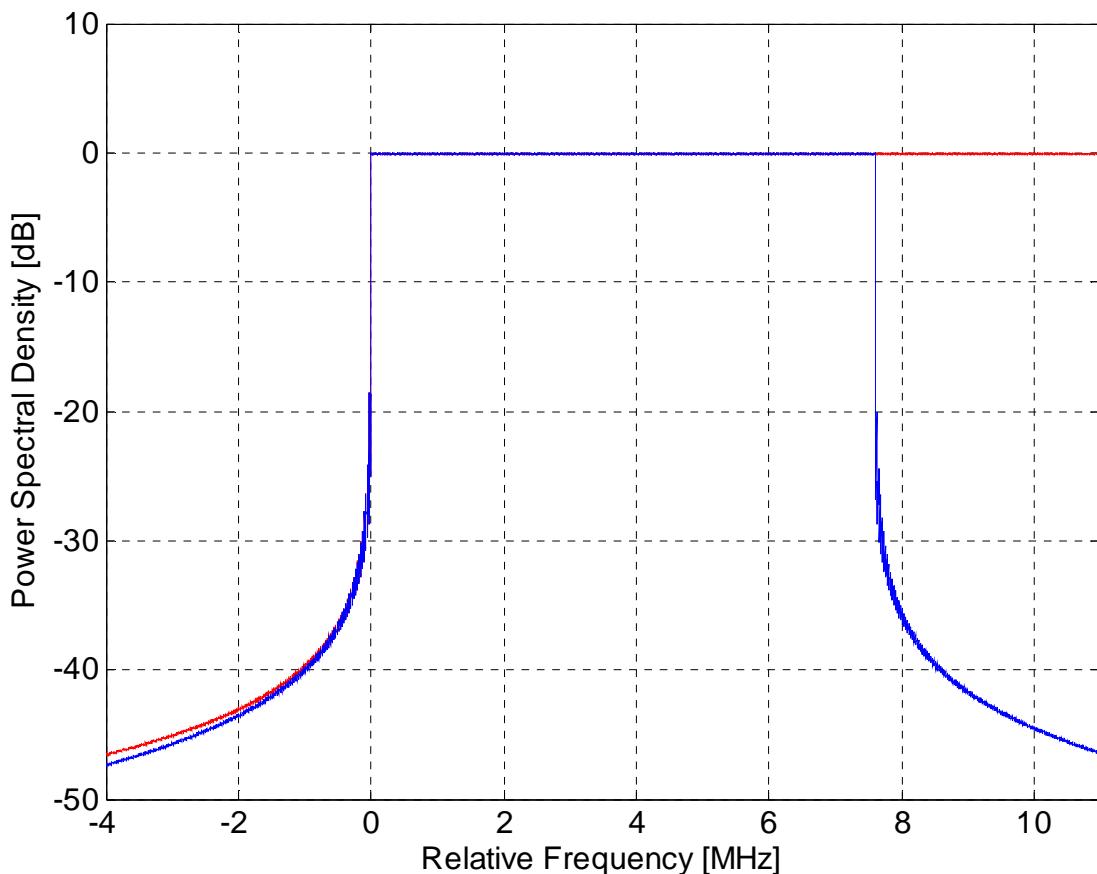

Figure 41: Theoretical DVB-C2 signal spectrum for guard interval fraction 1/128 and different signal bandwidths (8 MHz and 445 MHz (lower edge only))

No specific requirements are set in terms of the spectrum characteristics after amplification and filtering, since it is considered to be more appropriately defined by the relevant standardization authorities, depending on both the regions and the frequency bands in which the C2 System is to be deployed.

Annex C (normative): Input stream synchronizer

Delays and packet jitter introduced by DVB-C2 equipment may depend on the transmitted bit-rate and may change in time during bit and/or code rate switching. The "Input Stream Synchronizer" (see figure C.1) shall provide a mechanism to regenerate, in the receiver, the clock of the Transport Stream (or packetized Generic Stream) at the modulator Mode Adapter input, in order to guarantee end-to-end constant bit rates and delays (see also figure C2, example receiver implementation). Table C.1 gives the details of the coding of the ISSY field generated by the input stream synchronizer.

When ISSYI = 1 in MATYPE field (see clause 5.1.6) a counter shall be activated (22 bits), clocked by the modulator sampling rate (frequency $R_s=1/T$, where T is defined in clause 10.). The Input Stream Synchronization field (ISSY, 2 or 3 bytes) shall be transmitted according to clause 5.1.7.

ISSY shall be coded according to table C.1, sending the following variables:

- ISCR (short: 15 bits; long: 22 bits) (ISCR = Input Stream Time Reference), loaded with the LSBs of the counter content at the instant the relevant input packet is processed (at constant rate R_{IN}), and specifically the instant the MSB of the relevant packet arrives at the modulator input stream interface. In case of continuous streams the content of the counter is loaded when the MSB of the Data Field is processed.
- BUFS (2+10 bits) (BUFS = maximum size of the requested receiver buffer to compensate delay variations). This variable indicates the size of the receiver buffer assumed by the modulator for the relevant PLP. It shall have a maximum value of 2 Mbit. When a group of Data PLPs share a Common PLP, the sum of the buffer size for any Data PLP in the group plus the buffer size for the Common PLP shall not exceed 2 Mbit. This field shall not be transmitted in case of PLP bundling as the ISCR field is required in every BBFrame for sorting of the input stream.
- BUFSTAT (2+10 bits) (BUFSTAT = actual status to reset the receiver buffer = number of filled bits). If ISSYI=1, this variable shall be transmitted at least 5 times per second, replacing ISCR. This value can be used to set the receiver buffer status during reception start-up procedure, and to verify normal functioning in steady state. This field shall not be transmitted in case of PLP bundling as the ISCR field is required in every BBFrame for sorting of the input stream.

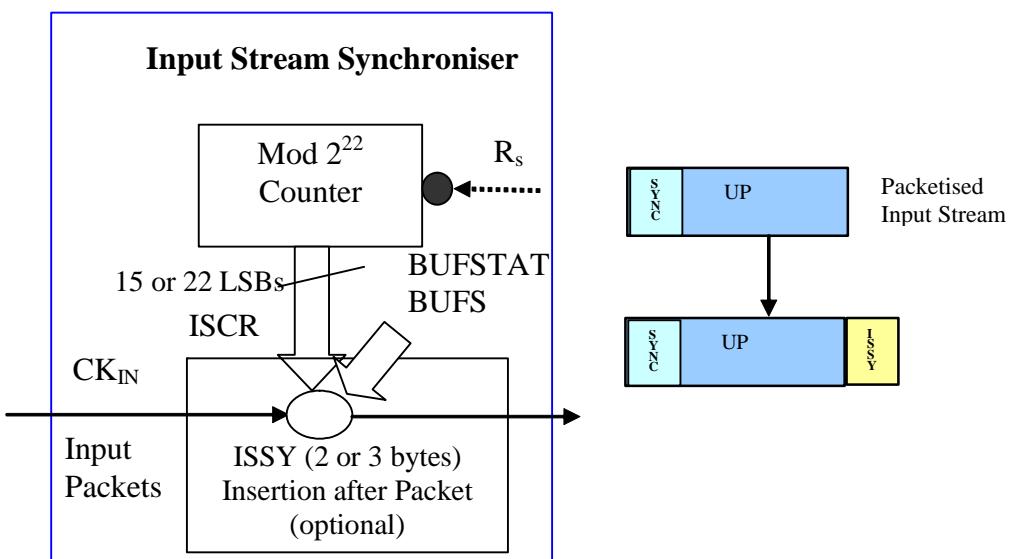

Figure C.1: Input stream synchronizer block diagram

Table C.1: ISSY field coding (2 bytes or 3 bytes)

First Byte					Second Byte	Third Byte
Bit-7 (MSB)	bit-6	bit-5 and bit-4	bit-3 and bit-2	bit-1 and bit-0	bit-7 to bit-0	bit-7 bit-0
0 = ISCR _{short}	MSB of ISCR _{short}	next 6 bits of ISCR _{short}			Next 8 bits of ISCR _{short}	Not present
1	0 = ISCR _{long}	6 MSBs of ISCR _{long}			Next 8 bits of ISCR _{long}	Next 8 bits of ISCR _{long}
1	1	00 = BUFS 00 = bits 01 = Kbits 10 = Mbits 11 = 8 Kbits	BUFS unit 00 = bits 01 = Kbits 10 = Mbits 11 = 8 Kbits	2 MSBs of BUFS	Next 8 bits of BUFS	Not present when ISCR _{short} is used; else reserved for future use
1	1	10 = BUFSTAT	BUFSTAT unit 00 = bits 01 = Kbits 10 = Mbits 11 = BUFS/1 024	2 MSBs of BUFSTAT	Next 8 bits of BUFSTAT	Not present when ISCR _{short} is used; else reserved for future use
1	1	Others = reserved for future use	Reserved for future use	Reserved for future use	Reserved for future use	Not present when ISCR _{short} is used; else reserved for future use

Annex D (normative):

Input Remultiplexing Subsystem: Splitting of input MPEG-2 Transport Streams into Data PLPs, generation of a Common PLP of a group of PLPs and insertion of Null Packets into Transport Streams

D.1 Overview

This annex defines a feature of the C2 System applicable in the case of transmission of multiple MPEG-2 Transport Streams [i.1] in a configuration of a group of PLPs and an associated Common PLP. It includes the processing (remultiplexing) that shall be applied for transporting N ($N \geq 2$) MPEG-2 TSs (TS₁ to TS_N) over $N+1$ Data PLPs (PLP₁ to PLP_{N+1}), one of which is the Common PLP (CPLP) of a group of PLPs, see figure D.1.

If this processing is not applied to a group of Transport Streams, there shall be no Common PLP for this group, and each PLP of the group shall carry the input TS without modification. When several groups of PLPs are used to carry TSs, each such group has its own independent extension functionality.

This annex also describes the processing that can be carried out by the receiver to reconstruct a single input TS from the received Data PLP and its corresponding Common PLP.

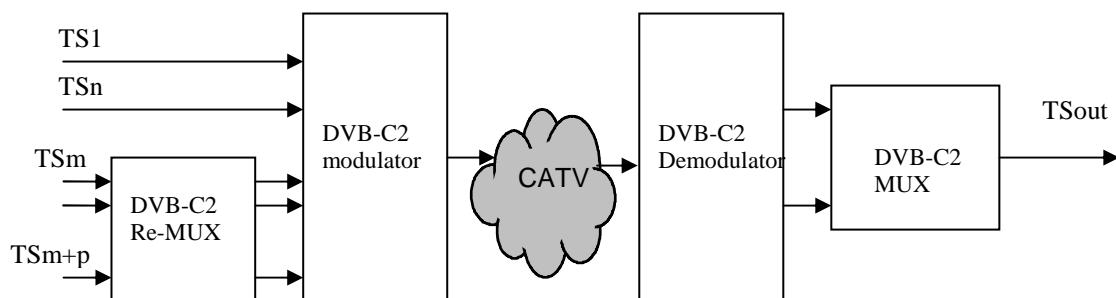

Figure D.1: Extended Re-multiplexing and Multiplexing Functionalities of DVB-C2

The extension consists on the network side conceptually of a remultiplexer and on the receiver side of a multiplexer. In-between the remultiplexer and the multiplexer we have the C2 System, as described in other parts of the present document. The inputs/outputs to the C2 System are syntactically correct TSs, each with unique transport_stream_ids, containing all relevant layer 2 (L2) signalling information (i.e. PSI/SI - see [i.1] and [i.4]). The various input TSs may have PSI/SI tables, or other L2 data, in common with other input TSs. When the extension is used the generated TSPS (Transport Stream Partial Stream) and TSPSC (Transport Stream Partial Stream Common) streams are however typically not syntactically correct MPEG-2 TSs, but are still carried in the MPEG-packet format.

NOTE: The parallel TSs may only exist internally in equipment generating the DVB-C2 signal. The parallel TSs may e.g. be generated from a single high bit rate TS source, or may alternatively be generated by centrally-controlled parallel encoders, each producing a constant bit rate TS, with variable proportion of Null Packets. The bit rates of the input TSs may be significantly higher than the capacity of the respective PLPs, because of the existence of a certain proportion of Null Packets, which are removed by the DNP procedure.

An input MPEG-2 TS shall be transported either:

- in its entirety within a single PLP, in which case the TS does not belong to any group of PLPs (and there is no Common PLP); or
- split into a TSPS stream, carried in a Data PLP, and a TSPSC stream, carried in the Common PLP. This annex specifies the splitting and describes how the recombination of the output streams from a Data PLP and a Common PLP can conceptually be achieved by the receiver to form the output TS.

D.2 Splitting of a group of input TSs into TSPSs streams and a TSPSC stream

D.2.1 General

When a set of N TSs (TS_1, ..., TS_N, N ≥ 2) are transmitted through a group of N+1 PLPs, one being the Common PLP of a group, all TSs may have a different input bit rate, but shall carry all the data packets, which are intended to be transmitted in a Common PLP. The data packets to be carried in the Common PLP are not necessarily co-timed.

However it is assumed that all TS in a group have been generated in the same Playout Centre and there may be a skew between those TS concerning the timing of the signals, caused amongst others by different propagation delays on the contribution links.

There are two steps of processing. In the first step TS packets, which shall be transmitted via the Common PLP shall be replaced by Null Packets and in the second step additional Null Packet are inserted in order to reduce the buffering requirements in the receivers.

Each TSPS shall have the same bit rate as the associated input TS and maintain the same time synchronization. The TSPSC is an elementary stream with the same bit rate as the input TS it was extracted from. It contains data packets common to all transport streams within the group of TSs in a certain Data Slice. TSPSC data shall not require time synchronization with the associated TSPS data. The DVB SI tables SDT or EIT shall not be transported via a Common PLP, as a processing of those tables at table_ID level is not foreseen in DVB-C2.

NOTE: The input TSs may contain a certain proportion of Null Packets. The split operation will not introduce further Null Packets into the TSPSs. Null packets will however be removed in the modulator and reinserted in the demodulator in a transparent way, so that the C2 System will be transparent for the TSPSs, despite Null Packets not being transmitted. Furthermore, the DNP and ISSY mechanism of the C2 System will ensure that time synchronization of the TSPSs and the TSPSC at the output of the demodulator is maintained to a certain extent.

D.2.2 Extraction of the Common PLP from a group of TS

For the purpose of specifying the split operation the TS packets that may be transmitted in the Common PLP are identified by one or several PIDs and fall into the following three categories:

- 1) TS packets carrying any type of data, which does not require an exact time synchronization with other TS packets carried in other PLPs of the related group of PLPs.
- 2) EPG data, e.g. based on Event Information Table (EIT) format, but not using the 'actual' and 'other' mechanisms as specified in [i.4].
- 3) Conditional Access control data, e.g. Entitlement Management Messages (EMMs).

DVB-SI TS packets that may not be transmitted in the Common PLP, as this would require complex remultiplexing functionalities, fall into the following two categories:

- 1) TS packets carrying Service Description Table (SDT), i.e. with PID value of 0x0011.
- 2) TS packets carrying Event Information Table (EIT), i.e. with PID value of 0x0012.

The TS packets targeted for transmission via the Common PLP shall be extracted from one input TS. If the input stream carrying the Common PLP data is carrying also payload data which is targeted to go into a PLP, those TS packets of that input stream, which were extracted to the Common PLP, shall be replaced by Null Packets (see figure D.2). All TS packets of the other input TSs belonging to that group of PLPs are processed such that all TS packets with the PID associated to the Common PLP are replaced by Null Packets.

During the process of extraction of Common PLP data optionally components of that TS may be deleted by replacement of the related data packets by Null Packets.

By processing one TS in parallel in two of the re-multiplexing lines and replacing complementary TS packets by Null Packets a separation of one TS into two partial TSs, which are targeted to be transmitted via different PLPs (with different level of robustness), can be achieved. This principle is also applicable if a split of one TS into more than two partial streams is required.

Figure D.2 is simplified insofar as it does not show any Null Packets in the input TSs. In real input TSs these are of course to be expected. The absence of these packets in the figures does however not in any way affect the general applicability of the splitting/re-combining process, as described in this annex.

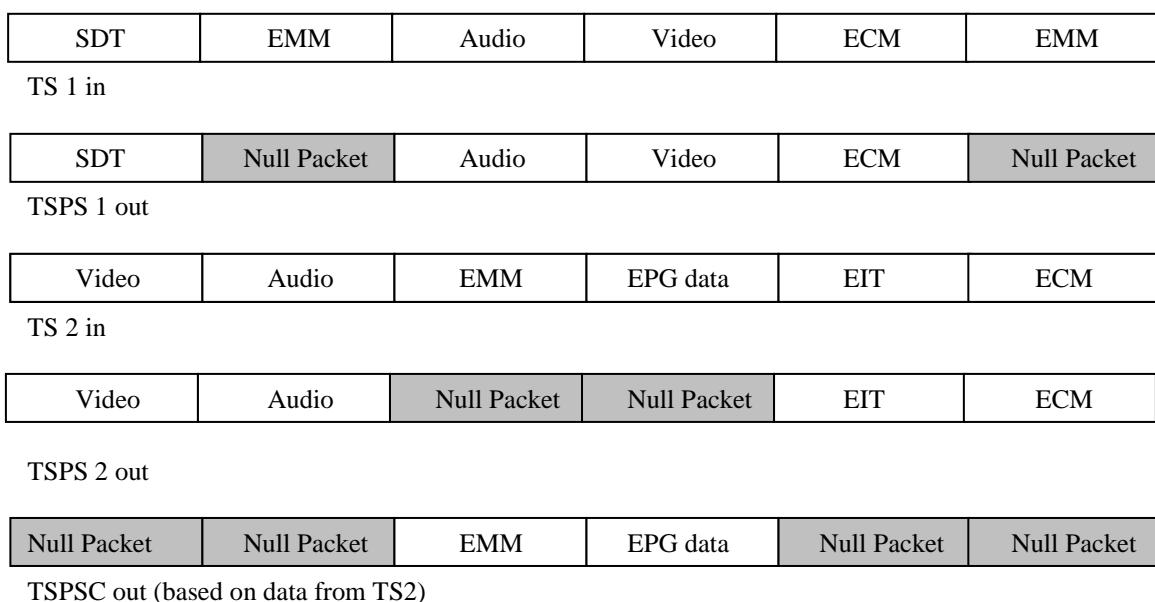

Figure D.2: Example of generation of two TSPS and a TSPSC form two input TS

D.2.3 Insertion of additional Null Packets into TSPSs

TS packets that are not necessarily co-timed but identical on all input TSs of the group before the split shall be replaced by Null Packets in the respective TSPS at the same time positions. Furthermore packets targeted to go into the common PLP may occur non equidistant in the input stream. If the data packets in the Common PLP do have a "bursty", characteristics and the packets of the Common PLP and the relevant Data PLP are not co-timed, the required buffer size in a receiver could be significantly increased due to the missing time correlation. The insertion of additional Null Packets in the TSPS allows smoothing the characteristics of Null Packets and thus reducing the buffer requirement in receivers.

The number of inserted Null Packets shall be chosen such that a receiver with a 2 Mbit buffer is able to perform the multiplexing of Data PLP and Common PLP properly.

After insertion of Null Packets a PCR restamping has to be performed.

Figure D.3 gives an example of two Transport Streams where after extraction of Common PLP packets additional Null Packets are inserted.

SDT	EMM	Audio	Video	ECM	EMM
TS 1					
SDT	Null Packet	Audio	Video	ECM	Null Packet
TSPS 1					
SDT	Null Packet	Audio	Null Packet	Video	ECM
TSPSS 1					
Video	Audio	EMM	EPG data	EIT	ECM
TS 2					
Video	Audio	Null Packet	Null Packet	EIT	ECM
TSPS 2					
Video	Null Packet	Audio	Null Packet	Null Packet	EIT
TSPSS 2					

Figure D.3: Example of insertion of Null Packets into two TS / TSPS

D.3 Receiver Implementation Considerations

In view of the key role played by the transport stream as a physical interface in many existing and future receivers it is strongly recommended that at least the core of the merging function as described in this annex is implemented in a channel decoder silicon chip. In particular this applies to the generic merging function between TSPSC and TSPS to form a transport stream for generic data as defined in clause D.2 illustrated in figure D.3.

The channel decoder implementations as defined above should ensure correct integration of many existing DVB system hardware and software solutions for DVB with such channel decoders.

D.3.1 Recombination of TSPSS and TSPSC in a receiver

The receiver shall recreate the targeted TS by multiplexing the received synchronized partial Transport Stream (TSPSS) with the received Common PLP Transport Stream (TSPSC). It shall replace any Null Packets which appear in the received TSPSS, by a packet from its Common PLP (TSPSC) buffer, unless this buffer is empty, see figure D.4. The output signal of the DVB-C2 demodulator delivers the Partial Transport Stream (TSPS) and the Common PLP (TSPSC) multiplexed together. Common PLP packets may be time shifted in relation to the modulator input signal and the amount of additionally inserted Null Packets at the modulator will increase the out data rate of the complete multiplexed output signal accordingly. However, after the PID filtering at the MPEG-Demultiplexer this headroom is removed completely.

Null Packet	Null Packet	EMM	EPG data	Null Packet	Null Packet
-------------	-------------	-----	----------	-------------	-------------

TSPSC

Video	Null Packet	Audio	Null Packet	Null Packet	EIT	ECM
-------	-------------	-------	-------------	-------------	-----	-----

TSPSS 2

Video	Null Packet	Audio	EMM	EPG data	EIT	ECM
-------	-------------	-------	-----	----------	-----	-----

TSS 2 (identical with TS2, except the inserted stuffing Null Packets)

Annex E (normative): Calculation of the CRC word

The implementation of Cyclic Redundancy Check codes (CRC-codes) allows the detection of transmission errors at the receiver side. For this purpose CRC words shall be included in the transmitted data. These CRC words shall be defined by the result of the procedure described in this annex.

A CRC code is defined by a polynomial of degree n :

$$G_n(x) = x^n + g_{n-1}x^{n-1} + \dots + g_2x^2 + g_1x + 1$$

with $n \geq 1$:

and: $g_i \in \{0,1\}, i = 1, \dots, n-1$

The CRC calculation may be performed by means of a shift register containing n register stages, equivalent to the degree of the polynomial (see figure E.1). The stages are denoted by $b_0 \dots b_{n-1}$, where b_0 corresponds to 1, b_1 to x , b_2 to x^2, \dots, b_{n-1} to x^{n-1} . The shift register is tapped by inserting XORs at the input of those stages, where the corresponding coefficients g_i of the polynomial are '1'.

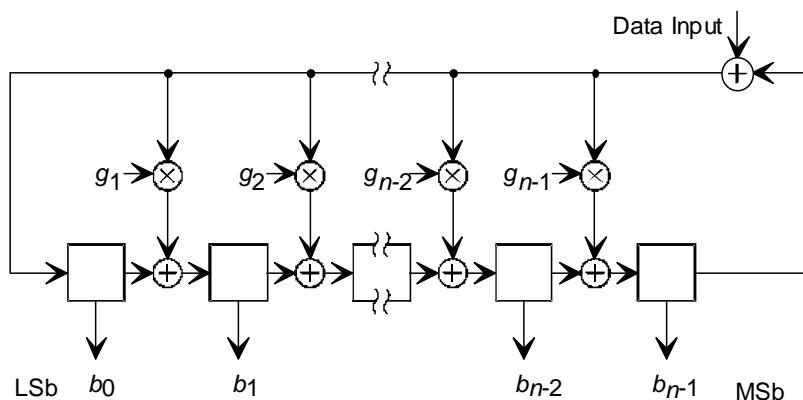

Figure E.1: General CRC block diagram

At the beginning of the CRC-8 calculation (used for GFPS and TS, NM only and BBHeader), all register stage contents are initialized to zeros.

At the beginning of the CRC-32 calculation, all register stage contents are initialized to ones.

After applying the first bit of the data block (MSB first) to the input, the shift clock causes the register to shift its content by one stage towards the MSB stage (b_{n-1}), while loading the tapped stages with the result of the appropriate XOR operations. The procedure is then repeated for each data bit. Following the shift after applying the Last Bit (LSB) of the data block to the input, the shift register contains the CRC word which is then read out. Data and CRC word are transmitted with MSB first.

The CRC codes used in the DVB-C2 system are based on the following polynomials:

- $G_{32}(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^8 + x^7 + x^5 + x^4 + x^2 + x + 1$
- $G_8(x) = x^8 + x^7 + x^6 + x^4 + x^2 + 1$

The assignment of the polynomials to the respective applications is given in each clause.

NOTE: The CRC-32 coder defined in this annex is identical to the implicit encoder defined in EN 300 468 [i.4].

Annex F (normative): Bundling of PLPs

In addition to the basic operation mode (i.e. one or several PLPs are located in one Data Slice) the C2 System allows spreading data of a single PLP connection over different Data Slices (PLP Bundling). As a result, the throughput rate for a single PLP connection can be increased up to the overall throughput rate of the C2 System. This operation mode is intended for advanced services that require throughput rates above the capacity of a single Data Slice.

All data packets of a bundled PLP connection shall pass the same input processing block. Inserting the ISSY timestamp in the mode adaptation block is mandatory for this operation mode in order to allow the correct reordering of the packets from different Data Slices on the receiver side. At the output of the input processing block the BBFrames of the bundled PLP are spread over the different Data Slices. Figure F.1 shows the block diagram for the PLP Bundling operation mode.

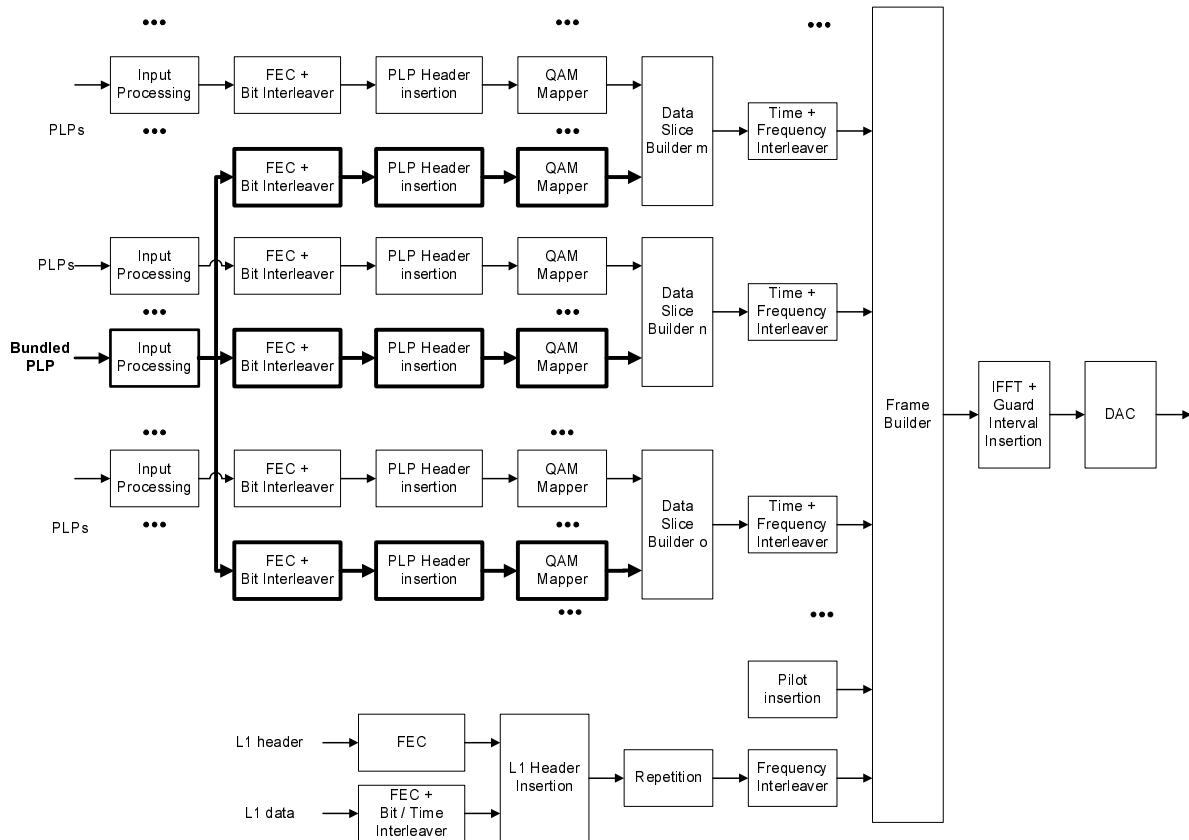

Figure F.1: Bundling PLP - data of a single PLP is spread over different Data Slices

The bundling PLP operation mode mandates the usage of the FECFrame header for the Data Slices that contain packets from the bundled PLP.

NOTE 1: As for the basic operation mode, Data Slices that include FECFrames from a bundled PLP might also contain FECFrame packets of others PLPs.

NOTE 2: C2 receivers with a single 8 MHz reception tuner do not need to decode bundled PLPs. These C2 receivers will recognize bundled PLPs from the L1 part 2 signalling and will discard associated Data Slice Packets.

Annex G (informative): Transport Stream regeneration and clock recovery using ISCR

When the modulator operates in a mode that employs Null Packet Deletion, the receiver may regenerate the Transport Stream by inserting, before each useful packet, DNP in the reception FIFO buffer. As shown in figure G.1, the Transport Stream clock R'_{IN} may be recovered by means of a Phase Locked Loop (PLL). The recovered modulator sampling rate R_s may be used to clock a local counter (which by definition runs synchronously with the input stream synchronization counter of figure G.1). The PLL compares the local counter content with the transmitted ISCR of each TS packet, and the phase difference may be used to adjust the R'_{IN} clock. In this way R'_{IN} remains constant, and the reception FIFO buffer automatically compensates the chain delay variations. Since the reception FIFO buffer is not self-balancing, the BUFSTAT and the BUFS information may be used to set its initial state.

As an alternative, when dynamic variations of the end-to-end delay and bit-rate may be acceptable by the source decoders, the receiver buffer filling condition may be used to drive the PLL. In this case the reception buffer is self-balancing (in steady state half the cells are filled), and the ISSY field may be omitted at the transmitting side.

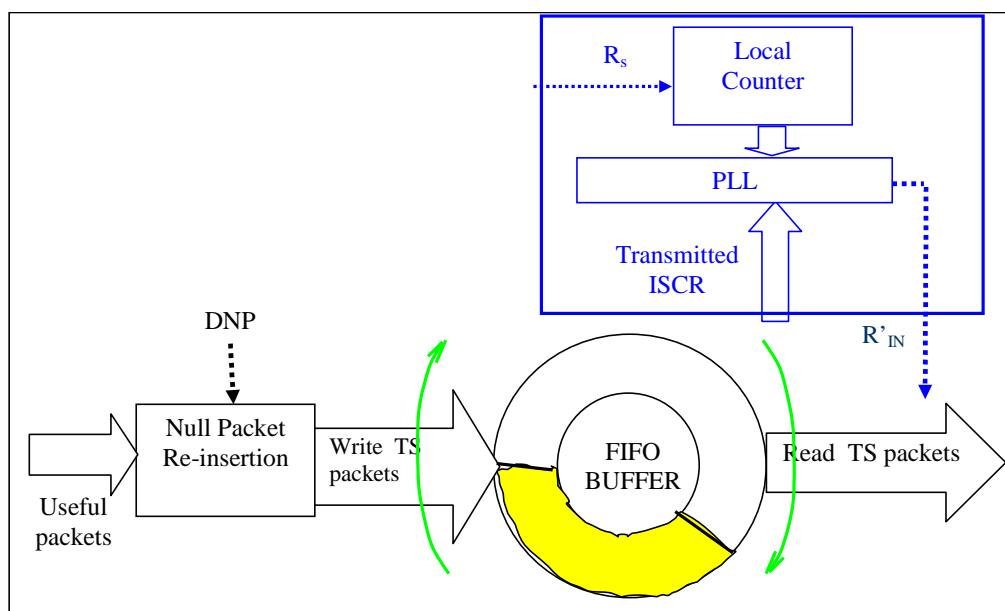

Figure G.1: Example receiver block diagram for Null Packet re-insertion and R_{TS} clock recovery

Annex H (informative): Pilot patterns

This annex illustrates each of the scattered pilot patterns, showing the pattern of pilots at the low frequency edge of the ensemble for the first a few symbols of a frame. There are two scattered pilot patterns, and each of them has four phases to start with depending upon the frequency of the low frequency edge. Figures H.1 to H.4 shows the patterns in GI 1/64 case with four different phases. Figures H.5 to H.8 show the pilot patterns in GI 1/128 with four different phases. Continual pilot carriers are not shown.

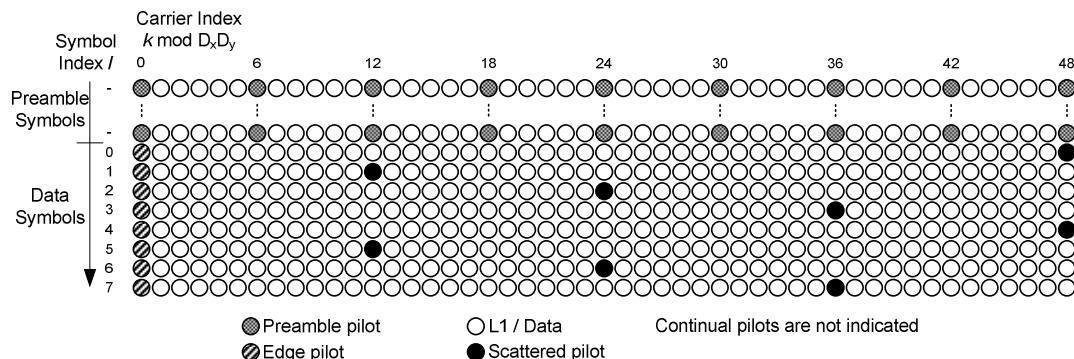

Figure H.1: Scattered pilot pattern for GI 1/64 with the lower edge $k \bmod D_x D_y = 0$

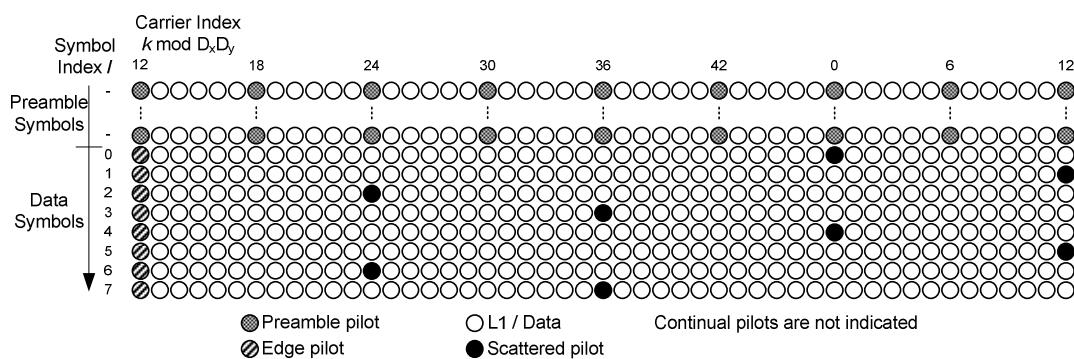

Figure H.2: Scattered pilot pattern for GI 1/64 with the lower edge $k \bmod D_x D_y = 12$

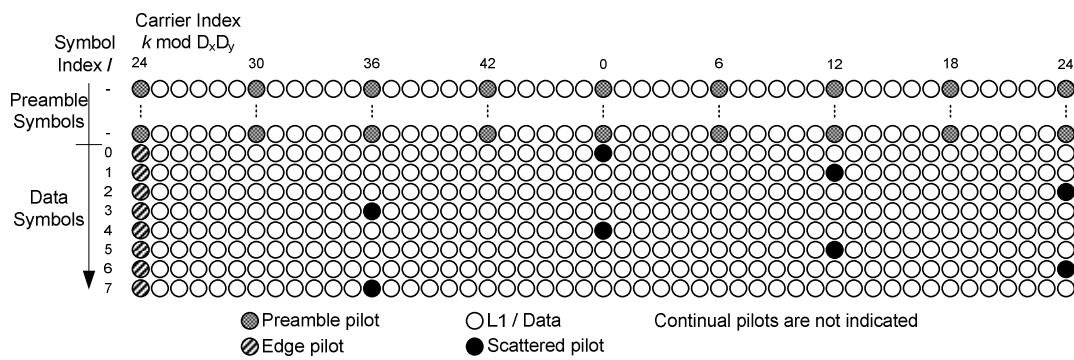

Figure H.3: Scattered pilot pattern for GI 1/64 with the lower edge $k \bmod D_x D_y = 24$

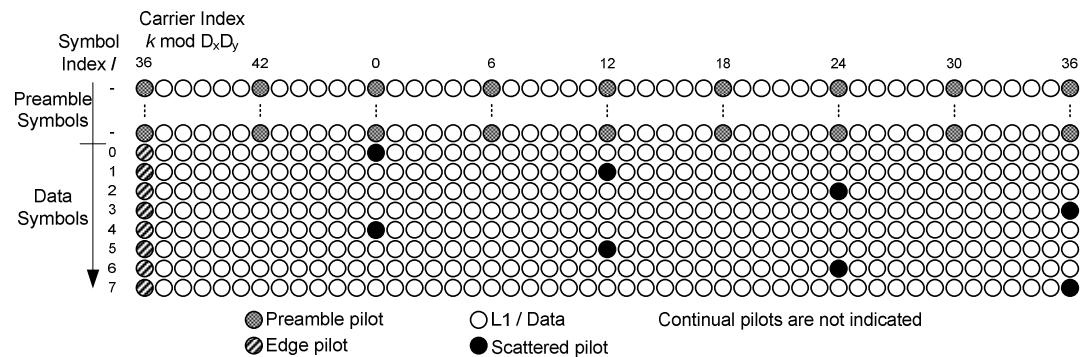

Figure H.4: Scattered pilot pattern for GI 1/64 with the lower edge $k \bmod D_x D_y = 36$

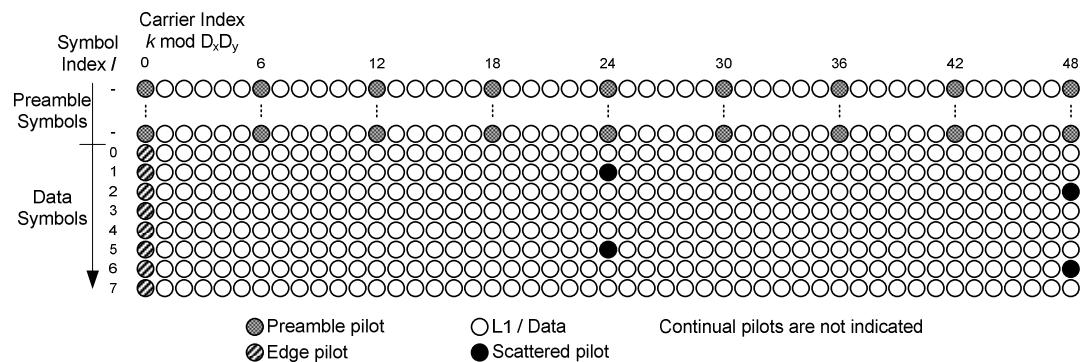

Figure H.5: Scattered pilot pattern for GI 1/128 with the lower edge $k \bmod D_x D_y = 0$

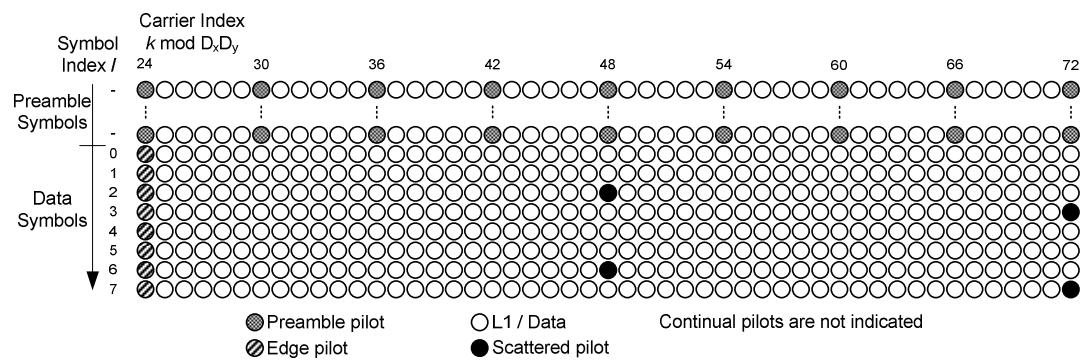

Figure H.6: Scattered pilot pattern for GI 1/128 with the lower edge $k \bmod D_x D_y = 24$

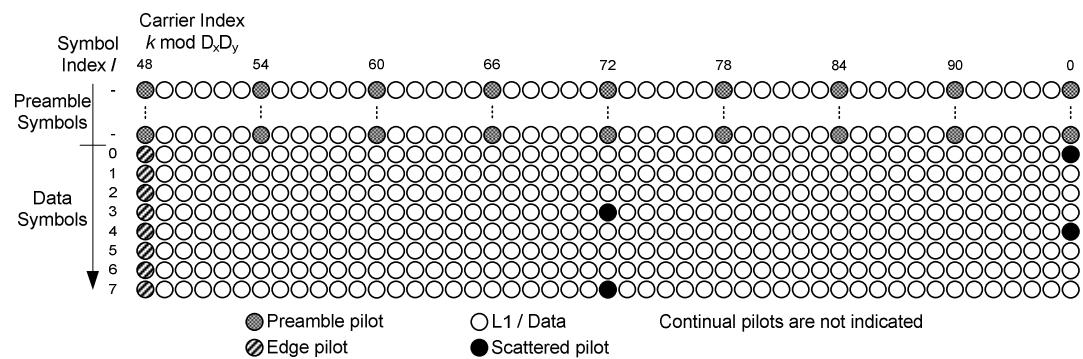

Figure H.7: Scattered pilot pattern for GI 1/128 with the lower edge $k \bmod D_x D_y = 48$

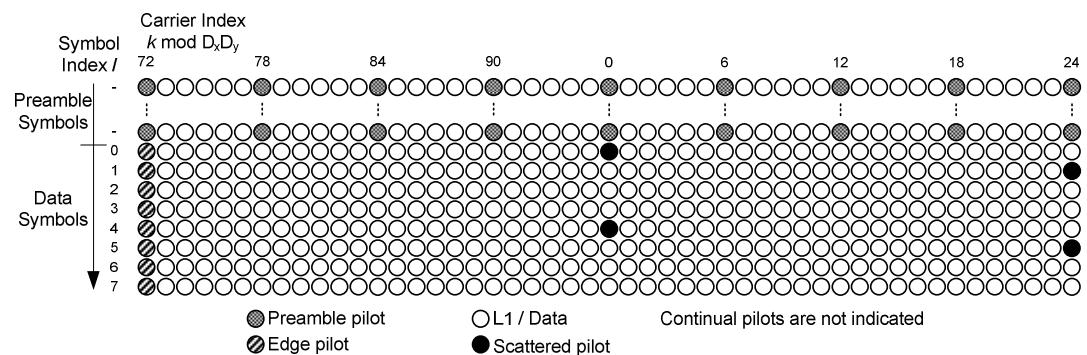

Figure H.8: Scattered pilot pattern for GI 1/128 with the lower edge $k \bmod D_x D_y = 72$
