Intellectual Property Rights

Essential patents

IPRs essential or potentially essential to normative deliverables may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for ETSI members and non-members, and can be found in ETSI SR 000 314: “Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards”, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (https://ipr.etsi.org/).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Trademarks

The present document may include trademarks and/or tradenames which are asserted and/or registered by their owners. ETSI claims no ownership of these except for any which are indicated as being the property of ETSI, and conveys no right to use or reproduce any trademark and/or tradename. Mention of those trademarks in the present document does not constitute an endorsement by ETSI of products, services or organizations associated with those trademarks.

Foreword

This ETSI Standard (ES) has been produced by ETSI Technical Committee Speech and multimedia Transmission Quality (STQ).

Modal verbs terminology

In the present document "shall", "shall not", "should", "should not", "may", "need not", "will", "will not", "can" and "cannot" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.

Introduction

Traditionally, analogue and digital telephones were interfacing switched-circuit 64 kbit/s PCM networks. With the fast growth of IP networks, terminals directly interfacing packet-switched networks (VoIP) are being rapidly introduced. Such IP network edge devices may include specifically designed IP phones, soft phones or other devices connected to the IP based networks, providing telephony service. Since the IP networks will be in many cases interworking with the traditional PSTN and private networks, many of the basic transmission requirements have to be harmonised with specifications for traditional digital terminals. However, due to the unique characteristics of the IP networks including packet loss, delay, etc. new performance specification, as well as appropriate measurement methods, will have to be developed. Terminals are getting increasingly complex. Advanced signal processing is used to address the IP specific issues. Also, the VoIP terminals may use other than 64 kbit/s PCM (Recommendation ITU-T G.711 [7]) speech coding algorithms.

The advanced signal processing of terminals is targeted to speech signals. Therefore, wherever possible speech signals are used for testing in order to achieve mostly realistic test conditions and meaningful results.

The present document provides speech transmission performance requirements for narrowband VoIP loudspeaking and hands-free terminals.

NOTE: Requirement limits are given in tables, the associated curve when provided is given for illustration.
1 Scope

The present document provides speech transmission performance requirements for narrowband VoIP loudspeaking and hands-free terminals; it addresses all types of IP based terminals, including wireless, softphones and group audio terminals.

DECT terminals are covered in ETSI EN 300 175-8 [i.6] and ETSI EN 300 176-2 [i.7].

In contrast to other standards which define minimum performance requirements it is the intention of the present document to specify terminal equipment requirements which enable manufacturers and service providers to enable good quality end-to-end speech performance as perceived by the user.

In addition to basic testing procedures, the present document describes advanced testing procedures taking into account further quality parameters as perceived by the user.

NOTE: The present document does not concern headset terminals.

2 References

2.1 Normative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at https://docbox.etsi.org/Reference.

NOTE: While any hyperlinks included in this clause were valid at the time of publication ETSI cannot guarantee their long term validity.

The following referenced documents are necessary for the application of the present document.

3 Definition of terms, symbols and abbreviations

3.1 Terms

For the purposes of the present document, the following terms apply:

**artificial ear:** device for the calibration of earphones incorporating an acoustic coupler and a calibrated microphone for the measurement of the sound pressure and having an overall acoustic impedance similar to that of the median adult human ear over a given frequency band

**codec:** combination of an analogue-to-digital encoder and a digital-to-analogue decoder operating in opposite directions of transmission in the same equipment

**ear-Drum Reference Point (DRP):** point located at the end of the ear canal, corresponding to the ear-drum position

**freefield equalization:** artificial head is equalized in such a way that for frontal sound incidence in anechoic conditions the frequency response of the artificial head is flat

**freefield reference point:** point located in the free sound field, at least in 1.5 m distance from a sound source radiating in free air

NOTE: In case of a head and torso simulator (HATS) in the centre of the artificial head with no artificial head present.

**group audio terminal:** handsfree terminal primarily designed for use by several users which will not be equipped with a handset

**handsfree telephony terminal:** telephony terminal using a loudspeaker associated with an amplifier as a telephone receiver and which can be used without a handset

**HATS Hands-Free Reference Point (HATS HFRP):** corresponds to a reference point "n" from Recommendation ITU-T P.58 [15]: "n" is one of the points numbered from 11 to 17 and defined in table 6a of Recommendation ITU-T P.58 [15] (coordinates of far field front point)

NOTE: The HATS HFRP depends on the location(s) of the microphones of the terminal under test: the appropriate axis lip-ring/HATS HFRP is to be as close as possible to the axis lip-ring/HFT microphone under test.
**Head And Torso Simulator (HATS) for telephonometry:** manikin extending downward from the top of the head to the waist, designed to simulate the sound pick-up characteristics and the acoustic diffraction produced by a median human adult and to reproduce the acoustic field generated by the human mouth.

**loudspeaking function:** function of a handset telephone using a loudspeaker associated with an amplifier as a telephone receiver.

**Mouth Reference Point (MRP):** point located on axis and 25 mm in front of the lip plane of a mouth simulator.

**nominal setting of the volume control:** setting which is closest to the nominal RLR.

**reordering:** packet order changes during transfer over the network \([i.5]\), packets arrive out of order at the receiver (i.e. RTP packets).

**softphone:** speech communication system based upon a computer.

**NOTE:** \(y\) being N for narrowband, M for mixed, S for super-wideband and F for fullband. See Recommendation ITU-T P.800.1 [24].
4 General considerations

4.1 Default Coding Algorithm

VoIP terminals shall support the coding algorithm according to Recommendation ITU-T G.711 [7] (both µ-law and A-law). VoIP terminals may support other coding algorithms.

NOTE: Packet Loss Concealment as defined in e.g. appendix I of Recommendation ITU-T G.711 [7] should be used.

4.2 End-to-end considerations

In order to achieve a desired end-to-end speech transmission performance (mouth-to-ear) it is recommended that general rules of transmission planning tasks are carried out with the E-model taking into account that E-model does not directly address handsfree or loudspeaking terminals; this includes the a-priori determination of the desired category of speech transmission quality as defined in Recommendation ITU-T G.109 [5].

While, in general, the transmission characteristics of single circuit-oriented network elements, such as switches or terminals can be assumed to have a single input value for the planning tasks of Recommendation ITU-T G.108 [4] this approach is not applicable in packet based systems and thus there is a need for the transmission planner's specific attention.

In particular the decision as to which delay measured according to the present document is acceptable or representative for the specific configuration is the responsibility of the individual transmission planner.

The following optimum terminal parameters from a user's perspective need to be considered:

- Minimized delay in send and receive direction.
- Optimum loudness rating (RLR, SLR).
- Compensation for network delay variation.
- Packet loss recovery performance.
- Maximized terminal coupling loss.
- Some more basic (ETSI I-ETS 300 245-3 [1]) parameters are applicable, if Recommendation ITU-T G.711 [7] is used.
5 Test equipment

5.1 IP half channel measurement adaptor

The IP half channel measurement adaptor is described in ETSI EG 202 425 [i.1].

5.2 Environmental conditions for tests

The following conditions shall apply for the testing environment:

a) Ambient temperature: 15 °C to 35 °C.

b) Relative humidity: 5 % to 85 %.

c) Air pressure: 86 kPa to 106 kPa (860 mbar to 1 060 mbar).

5.3 Accuracy of measurements and test signal generation

Unless specified otherwise, the accuracy of measurements made by test equipment shall be equal to or better than:

<table>
<thead>
<tr>
<th>Item</th>
<th>Accuracy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electrical signal level</td>
<td>±0,2 dB for levels ≥ -50 dBV</td>
</tr>
<tr>
<td></td>
<td>±0,4 dB for levels &lt; -50 dBV</td>
</tr>
<tr>
<td>Sound pressure</td>
<td>±0,7 dB</td>
</tr>
<tr>
<td>Frequency</td>
<td>±0,2 %</td>
</tr>
<tr>
<td>Time</td>
<td>±0,2 %</td>
</tr>
<tr>
<td>Application force</td>
<td>±2 N</td>
</tr>
<tr>
<td>Measured maximum frequency</td>
<td>20 kHz</td>
</tr>
<tr>
<td>NOTE: The measured maximum frequency is</td>
<td>due to P.58 limitations [15].</td>
</tr>
<tr>
<td>due to P.58 limitations [15].</td>
<td></td>
</tr>
</tbody>
</table>

Unless specified otherwise, the accuracy of the signals generated by the test equipment shall be better than:

<table>
<thead>
<tr>
<th>Quantity</th>
<th>Accuracy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sound pressure level at Mouth Reference Point (MRP)</td>
<td>±3 dB for frequencies from 100 Hz to 200 Hz</td>
</tr>
<tr>
<td></td>
<td>±1 dB for frequencies from 200 Hz to 4 000 Hz</td>
</tr>
<tr>
<td></td>
<td>±3 dB for frequencies from 4 000 Hz to 8 000 Hz</td>
</tr>
<tr>
<td>Electrical excitation levels</td>
<td>±0,4 dB across the whole frequency range</td>
</tr>
<tr>
<td>Frequency generation</td>
<td>±2 % (see note)</td>
</tr>
<tr>
<td>Time</td>
<td>±0,2 %</td>
</tr>
<tr>
<td>Specified component values</td>
<td>±1 %</td>

<td>measurements at critical frequencies, e.g.</td>
</tr>
<tr>
<td>measurements at critical frequencies, e.g.</td>
<td>those due to sampling operations within the</td>
</tr>
<tr>
<td>due to sampling operations within the</td>
<td>terminal under test.</td>
</tr>
<tr>
<td>terminal under test.</td>
<td></td>
</tr>
</tbody>
</table>

For terminal equipment which is directly powered from the mains supply, all tests shall be carried out within ±5 % of the rated voltage of that supply. If the equipment is powered by other means and those means are not supplied as part of the apparatus, all tests shall be carried out within the power supply limit declared by the supplier. If the power supply is a.c., the test shall be conducted within ±4 % of the rated frequency.
5.4 Network impairment simulation

At least one set of requirements is based on the assumption of an error free packet network, and at least one other set of requirements is based on a defined simulated loss of performance of the packet network.

An appropriate network simulator has to be used, for example Netem™ [i.3].

The key points of Netem™ can be summarized as follows:

- Netem™ is part of the networking function of Linux™. With Netem™, there can be generated loss, duplication, delay, jitter and reordering (and the distribution of jitter can be chosen during runtime). Netem™ can be run on a Linux™-PC running as a bridge or a router.

- It is not advised to define specific distortion patterns for testing in standards, because it will be easy to adapt devices to these patterns (as it is already done for test signals). But if a pattern is unknown to a manufacturer, the same pattern can be used by a test lab for different devices and gives comparable results.

NOTE: Netem™ and Linux™ are examples of suitable products available commercially. This information is given for the convenience of users of the present document and does not constitute an endorsement by ETSI of these product(s).

Requirements for the network impairment simulation can be found in annex D of ETSI ES 202 737 [28].

5.5 Acoustic environment

Unless stated otherwise measurements shall be conducted under quiet and "anechoic" conditions. Depending on the distance of the transducers from mouth and ear a quiet office room may be sufficient e.g. for handsets where artificial mouth and artificial ear are located close to the acoustical transducers. But this is not applicable for handsfree and loudspeaking terminals.

In cases where real or simulated background noise is used as part of the testing environment, the original background noise shall not be noticeably influenced by the acoustical properties of the room.

In all cases where the performance of acoustic echo cancellers shall be tested, a realistic room, which represents the typical user environment for the terminal shall be used.

In case where an anechoic room is not available the test room has to be an acoustically treated room with few reflections and a low noise level.

Considering this, the test laboratory, in the case where its test room does not conform to anechoic conditions as given in Recommendation ITU-T P.342 [19], has to present difference in results for measurements due to its test room.

Standardized measurement methods for measurements with variable echo paths are for further study.

5.6 Influence of terminal delay on measurements

As delay is introduced by the terminal, care shall be taken for all measurements where exact position of the analysis window is required. It shall be checked that the test is performed on the test signal and not on any other signal.
6 Requirements and associated measurement methodologies

6.1 Notes

NOTE 1: In general the test methods as described in the present document apply. If alternative methods exist they may be used if they have been proven to give the same result as the method described in the standard. This will be indicated in the test report.

NOTE 2: Due to time variant nature of IP connection, delay variation may impair the measurement. In such case, the measurement has to be repeated until a valid measurement can be achieved.

6.2 Test setup

6.2.1 General

In order to use a compatible test system for all types of speech terminals a HATS (Head and Torso Simulator) will be used instead of freefield microphone (for receive measurement) and artificial mouth (for Send measurement). HATS is described in Recommendation ITU-T P.58 [15].

The preferred way of testing a terminal is to connect it to a network simulator with exact defined settings and access points. The test sequences are fed in either electrically, using a reference codec or using the direct signal processing approach or acoustically using ITU-T specified devices.

When a coder with variable bit rate is used for testing terminal electro acoustical parameters, the bit rate recognized giving the best characteristics should be selected, e.g.:

- AMR-NB (ETSI TS 126 171 [3]): 12.2 kbit/s.

![Figure 1: Half channel terminal measurement](image-url)
6.2.2 Setup for terminal

6.2.2.1 Hands-free measurements
The ear used for measurement shall be indicated in the test report.

Desktop operated hands-free terminal
For HATS test equipment, the definition of hands-free terminals and setups for hands-free terminal can be found in Recommendation ITU-T P.581 [22].

Handheld hands-free terminal
It should be placed in accordance to Figure 4. The HATS should be positioned so that the HATS Reference Point is at a distance $d_{HF}$ from the centre point of the visual display of the Mobile Station. The distance $d_{HF}$ is specified by the manufacturer. A vertical angle $\theta_{HF}$ may be specified by the manufacturer.
Figure 4: Configuration of Hand-Held loudspeaker relative to the HATS side view

\[ d_{HF} = d_{HF}, \quad d_{HFS} = d_{HF} - d_{EM}, \]
where \( d_{HFR} \) is the distance for receive measurement, \( d_{HFS} \) is the distance for Send measurement, and \( d_{EM} \) is the distance from ERP to MRP.

When no operating distance is specified by manufacturer, value for \( d_{HFS} \) will be 30 cm. A calculation of \( d_{EM} \) for HATS gives 12 cm.

A value of 42 cm will be taken for \( d_{HF} \).

**Softphone (computer-based terminals)**

Two types of softphones are to be considered:

- Type 1 is to be used as a desktop type (e.g. notebook).
- Type 2 is to be used as a handheld type (e.g. PDA).

When manufacturer gives conditions of use, they will apply for test.

If no other requirement is given by manufacturer softphone will be positioned according to the following conditions.

**Softphone including speakers and microphone**
Figure 6: Configuration of softphone relative to the HATS top sight

Softphone with separate speakers

When separate loudspeakers are used, system will be positioned as in Figure 7.

Figure 7: Configuration of softphone using external speakers relative to the HATS top sight
When external microphone and speakers are used, system will be positioned as in Figure 8.

**Figure 8: Configuration of softphone using external speakers and microphone relative to the HATS top sight**

**Group audio terminal**

When manufacturer gives conditions of use, they will apply for test.

When no requirement from manufacturer is given, the following conditions will be used by test laboratory.

Measurement will be conducted by using a HATS test equipment.

The following test position will be used.

**Figure 9: Configuration of group audio terminal relative to the HATS side view**
Figure 10: Configuration of group audio terminal relative to the HATS top sight

NOTE: In case of special casing where those conditions are not realistic, test laboratory can use a different position more representative of real use. The conditions of test will be given in the test report.

6.2.2.2 Measurements in loudspeaking mode

For those measurements HATS will be used.

It will be positioned as defined in clause 6.2.2. Measurement will be performed on one ear and handset will be placed on the other ear. The ear used for measurement will be specified in test report. For the handset 8N application force shall be used.

NOTE: Only desktop terminals are concerned by loudspeaking measurement.

6.2.3 Test signal levels

6.2.3.1 Send

Unless specified otherwise, the test signal level shall be -4,7 dBPa at the MRP.

The various steps for calibration of the artificial mouth of the HATS are described in Recommendation ITU-T P.581 [22].

The test setup shall be in conformance with Figure 11 but, depending on the type of terminal, the appropriate distance and level will be used. When using this calibration method, send sensitivity shall be calculated as follows:

\[ S_{\text{bl}} = 20 \log V_s - 20 \log P_{\text{MRP}} + \text{Corr} - D_{\text{corr}} \]

where:

- \( V_s \) is the measured voltage across the appropriate termination (unless stated otherwise, a 600 \( \Omega \) termination).
- \( P_{\text{MRP}} \) is the applied sound pressure at the MRP.
- \( \text{Corr} \) is 20 log (PMRP/PHFRP) of the artificial mouth used.

The value of Corr is the value required to calibrate the artificial mouth to the exact value of Dcorr (e.g. 24,0 dB for 50 cm distance).
• Dcorr is the correction to achieve the target sound pressure level at the intended distance (see below).

NOTE: Reason for this procedure of calibration in two steps is to take into account the different variation of signal with distance by using different implementations of HATS.

Figure 11: Calibration at HFRP

The distance used for level calibration corresponds to the following values:

- Desktop terminal: 50 cm and level to adjust -28,7 dBPa, Dcorr = 24 dB.
- Handheld terminal: 30 cm with -24,3 dBPa, Dcorr = 19.6 dB.
- Softphone: 36 cm with -25,8 dBPa, Dcorr = 21.1 dB.
- Group audio terminal: 85 cm with -33,3 dBPa, Dcorr = 28.6 dB.

6.2.3.2 Receive

Unless specified otherwise, the test signal level at the digital input shall be -16 dBm0.

All measurement values produced by HATS are intended to be freefield equalized.

6.2.4 Setup of background noise simulation

A setup for simulating realistic background noises in a lab-type environment is described in ETSI TS 103 224 [25].

If not stated otherwise this setup is used in all measurements where background noise simulation is required. The following noises of ETSI TS 103 224 [25] shall be used.

<table>
<thead>
<tr>
<th>Pub Noise (Pub)</th>
<th>HATS and microphone array in a pub</th>

</tr>
</tbody>
</table>
6.2.5 Setup for variable echo path

Test setup for desktop hands free terminals: A notebook is positioned at least 20 cm in front of the device (or devices) with the transducers, as shown in Figure 12. The notebook lid is moved during the measurement.

![Figure 12: Positioning of DUT](image1)

Test setup for softphone: The test setup is described in clause 6.2. The notebook lid is moved during the measurement, as shown in Figure 13. This setup is valid for all combinations of notebook with or without external speakers or microphone.

![Figure 13: Positioning of DUT](image2)

Test setup for other handsfree devices: for further study.

NOTE: Care should be taken to not generate noise during the movement of the notebook lid. Because of this, this measurement is not applicable for a softphone without external microphone.

6.3 Coding independent parameters

6.3.1 Send frequency response

Requirement

The Send sensitivity/frequency response shall be within the limits given in Table 4.
<table>

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

**Figure 14: Send frequency response mask for HFT**

**Measurement method**

The terminal will be positioned as described in clause 6.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20]. The spectrum of acoustic signal produced by the artificial mouth is calibrated under freefield conditions at the MRP. The signal level is adjusted according to clause 6.2.3.1.

Measurements shall be made at one third-octave bands as given by IEC 61260-1 [23] for frequencies from 100 Hz to 4 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBV/Pa.

**6.3.2 Send Loudness Rating (SLR)**

**Requirement**

The value of SLR shall be $+13 \text{ dB} \pm 3 \text{ dB}$.

This value is derived from Recommendation ITU-T P.310 [17]. According to Recommendation ITU-T P.340 [18] the SLR of a hands-free telephone should be about 5 dB higher than the SLR of the corresponding handset telephone.
This value will be identical for all type of terminal (desktop, handheld, etc.). Difference in efficiency will be given by conditions for measurement (see clause 6.2).

**Measurement method**

The terminal will be positioned as described in clause 6.2.

For a correct activation of the system, the test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20]. The spectrum of the acoustic signal produced by the artificial mouth is calibrated under freefield conditions at the MRP. The test signal level shall be -4.7 dBPa, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

Calibration is realized as explained in clause 6.2.3.1.

The send sensitivity shall be calculated from each band of the 14 frequencies given in table 1 of Recommendation ITU-T P.79 [16], bands 4 to 17. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band at the MRP.

SLR shall be calculated according Recommendation ITU-T P.79 [16].

### 6.3.3 Mic mute

**Requirement**

The Send Loudness Rating (SLR) with mic mute on shall be at least 50 dB higher than with mic mute off.

**Measurement method**

The terminal will be positioned as described in clause 6.2.

For a correct activation of the system, the test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20]. The spectrum of the acoustic signal produced by the artificial mouth is calibrated under freefield conditions at the MRP. The test signal level shall be -4.7 dBPa, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

Calibration is realized as explained in clause 6.2.3.1.

The send sensitivity shall be calculated from each band of the 14 frequencies given in table 1 of Recommendation ITU-T P.79 [16], bands 4 to 17. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band at the MRP.

The sensitivity is expressed in terms of dBV/Pa and the SLR shall be calculated according to Recommendation ITU-T P.79 [16], annex A.

### 6.3.4 Send distortion

**Requirement**

The terminal will be positioned as described in clause 6.2.

The ratio of signal to harmonic distortion shall be above the following mask.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>315 Hz</td>
<td>26 dB</td>
</tr>
<tr>
<td>400 Hz</td>
<td>30 dB</td>
</tr>
<tr>
<td>1 kHz</td>
<td>30 dB</td>
</tr>
</tbody>
</table>

**Note:** Limits at intermediate frequencies lie on a straight line drawn between the given values on a linear (dB ratio) - logarithmic (frequency) scale.
Measurement method

The terminal will be positioned as described in clause 6.2.

The signal used is an activation signal followed by a sine wave signal with a frequency at 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz and 1 000 Hz. The duration of the sine-wave shall be of less than 1 s. The sinusoidal signal level shall be calibrated to -4,7 dBPa at the MRP.

The signal to harmonic distortion ratio is measured selectively up to 3,15 kHz.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. The level of this activation signal shall be -4,7 dBPa at the MRP.

NOTE: Depending on the type of codec the test signal used may need to be adapted.

6.3.5 Out-of-band signals in send direction

Requirement

With any signal above 4,6 kHz and up to 8 kHz applied at the MRP at a level of -4,7 dBPa, the level of any image frequency shall be below the level obtained for the reference signal by at least the amount (in dB) specified in Table 6.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>4,6 kHz</td>
<td>30 dB</td>
</tr>
<tr>
<td>8 kHz</td>
<td>40 dB</td>
</tr>
</tbody>
</table>

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Measurement method

The terminal will be positioned as described in clause 6.2.

The female speaker of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. The level of this activation signal shall be -4,7 dBPa at the MRP.

For the test, an out-of-band signal shall be provided as a frequency band signal centred on 4,65 kHz, 5 kHz, 6 kHz, 6,5 kHz, 7 kHz and 7,5 kHz respectively. The level of any image frequencies at the digital interface shall be measured.

The levels of these signals shall be -4,7 dBPa at the MRP.

The complete test signal is constituted by t1 ms of in-band signal (reference signal), t2 ms of out-of-band signal and another time t1 ms of in-band signal (reference signal).

The observation of the output signal on the first and second in-band signals permits control if the set is correctly activated during the out-of-band measurement. This measurement shall be performed during t2 period:

- a value of 250 ms is suggested for t1;
- t2 depends on the integration time of the analyser, typically less than 150 ms.

6.3.6 Send noise

Requirement

The limit for the Send noise is the following:

- send noise level maximum -64 dBm0p.

No peaks in the frequency domain higher than 10 dB above the average noise spectrum shall occur.
Requirement as for other tests is identical for all types of terminals.

NOTE: Softphones with cooling devices (fans) can produce a rather high level of noise, furthermore largely dependent of activity of system.

Measurement method

The terminal will be positioned as described in clause 6.2.

The female speaker of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. The level of this activation signal shall be -4,7 dBPa at the MRP.

The psophometric noise level at the output of the test setup is measured. The psophometric filter is described in Recommendation ITU-T O.41 [12].

Spectral peaks are measured in the frequency domain in the frequency range from 100 Hz to 3,4 kHz. The frequency spectrum of the idle channel noise is measured by a spectral analysis having a noise bandwidth of 8,79 Hz (determined using FFT 8 k samples/48 kHz sampling rate with Hanning window or equivalent). The idle channel noise spectrum is stated in dB. A smoothed average idle channel noise spectrum is calculated by a moving average (arithmetic mean) 1/3rd octave wide across the idle noise channel spectrum stated in dB (linear average in dB of all FFT bins in the range from $2^{-1/6}f$ to $2^{+1/6}f$). Peaks in the idle channel noise spectrum are compared against a smoothed average idle channel noise spectrum.

6.3.7 Terminal Coupling Loss weighted (TCLw)

Requirement

The TCLw shall be $\geq 46$ dB for all settings of the volume control (if supplied).

NOTE: A TCLw $\geq 50$ dB is recommended as a performance objective. Depending on the idle channel noise in the sending direction, it may not always be possible to measure an echo loss $\geq 50$ dB.

Measurement method

The setup for terminal is described in clause 6.2.

For hands-free measurement, the HATS is positioned but not used.

For loudspeaking measurement, the handset is positioned on HATS (right ear).

The test signal is the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [20].

The TCLw is calculated according to Recommendation ITU-T G.122 [6], clause B.4 (trapezoidal rule). For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band.

6.3.8 Stability loss

Requirement

For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band. It shall exceed 6 dB for all frequencies and for all settings of volume control.

Measurement method

For handsfree mode the test set-up is identical as for TCLw.

For loudspeaking mode handset is placed at 50 cm beside terminal with transducers facing the table as in Figure 15.
Before the actual test a training sequence consisting of the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20] shall be applied. The training sequence level shall be -16 dBm0 in order not to overload the codec.

The test signal is a PN sequence complying with Recommendation ITU-T P.501 [20] with a length of 4 096 points (for the 48 kHz sampling rate) and a crest factor of 6 dB. The duration of the test signal is 250 ms. With an input signal of -3 dBm0, the attenuation from digital input to digital output shall be measured for frequencies from 200 Hz to 4 kHz.

6.3.9 Receive frequency response

**Requirement**

The following masks are required for handsfree and loudspeaking terminals.

**Desktop operated loudspeaker**

**Table 7: Receive frequency response mask-desktop**

<table>
<thead>

<tr>
<td>4000 Hz</td>
<td>6 dB</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Figure 17: Receive frequency response mask for Hand-held HFTs
Softphone (computer-based terminals)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Group audio terminal

Same requirement as desktop terminals.

**Measurement method**

Test setup is described in clause 6.2.

Measurement is operated at nominal value of volume control.

Receive frequency response is the ratio of the measured sound pressure and the input level. (dB relative Pa/V).

\[ S_{\text{eff}} = 20 \log \left( \frac{p_{\text{eff}}}{v_{\text{RCV}}} \right) \text{ dB rel 1 Pa/V} \] (1)

Where:

- \( S_{\text{eff}} \) Receive Sensitivity; Junction to HATS Ear with freefield correction.
- \( p_{\text{eff}} \) DRP Sound pressure measured by ear simulator Measurement data are converted from the Drum Reference Point to freefield.
- \( v_{\text{RCV}} \) Equivalent RMS input voltage.

The test signal to be used for the measurements shall be British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20]. The test signal level shall be -20 dBm0, measured according to Recommendation ITU-T P.56 [14] at the digital reference point or the equivalent analogue point.

The HATS is freefield equalized as described in Recommendation ITU-T P.581 [22]. The equalized output signal is power-averaged on the total time of analysis. The 1/3 octave band data are considered as the input signal to be used for calculations or measurements.

Measurements shall be made at one third-octave bands as given by the IEC 61260-1 [23] for frequencies from 100 Hz to 4 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBPa/V.

### 6.3.10 Receive Loudness Rating (RLR)

**Requirement**

**Desktop operated loudspeaker**

Nominal value of RLR will be 5 ± 3 dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range shall be less than (louder) or equal to -2 dB: RLR max ≤ -2 dB.

Range of volume control shall be equal or exceed 15 dB.

**Handheld terminal**

Nominal value of RLR will be 9 ± 3 dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range shall be less than (louder) or equal to 5 dB: RLR max ≤ 5 dB.

Range of volume control shall be equal or exceed 15 dB.
Softphone (computer-based terminal)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Group audio terminal

Nominal value of RLR will be $5 \pm 3$ dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range shall be less than (louder) or equal to -6 dB: $RLR_{\text{max}} \leq -6$ dB.

Range of volume control shall be equal or exceed 19 dB.

**Measurement method**

Test setup is described in clause 6.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20]. The test signal level shall be -20 dBm0, measured according to Recommendation ITU-T P.56 [14] at the digital reference point or the equivalent analogue point.

The receive sensitivity shall be calculated from each band of the 14 frequencies given in table 1 of Recommendation ITU-T P.79 [16], bands 4 to 17. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dB Pa/V and the RLR shall be calculated according to the formula 5-1 of Recommendation ITU-T P.79 [16], using the receive weighting factors from table 1 and according to clause 6, of Recommendation ITU-T P.79 [16]. The RLR shall then be corrected as $RLR - 14$ dB according to Recommendation ITU-T P.340 [18], and without the LE factor.

### 6.3.11 Receive Distortion

**Requirement**

Desktop operated loudspeaker

The ratio of signal to harmonic distortion shall be above the following mask.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Signal to distortion ratio limit, receive for desktop terminal at nominal volume</th>
<th>Signal to distortion ratio limit, receive for handheld terminal at nominal volume</th>
<th>Signal to distortion ratio limit, receive for all terminals at maximum volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>315 Hz</td>
<td>26 dB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>400 Hz</td>
<td>30 dB</td>
<td></td>
<td></td>
</tr>
<tr>
<td>500 Hz</td>
<td>30 dB</td>
<td>20 dB</td>
<td></td>
</tr>
<tr>
<td>800 Hz</td>
<td>30 dB</td>
<td>30 dB</td>
<td>20 dB</td>
</tr>
<tr>
<td>1 kHz</td>
<td>30 dB</td>
<td>30 dB</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:** The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Handheld terminal

The terminal will be positioned as described in clause 6.2.

The ratio of signal to harmonic distortion is given in Table 9.

Softphone (computer-based terminal)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.
Group audio terminal

Same requirement as for desktop terminal.

**Measurement method**

Test setup is described in clause 6.2.

The signal used is an activation signal followed by a sine wave signal with a frequency at 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz and 1 000 Hz. The duration of the sine-wave shall be of less than 1 s. Appropriate signals for activation and signal combinations can be found in Recommendation ITU-T P.501 [20]. The sinusoidal signal level shall be calibrated to -16 dBm0.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. Level of this activation signal shall be -16 dBm0.

The signal to harmonic distortion ratio is measured selectively up to 10 kHz.

*NOTE:* Depending on the type of codec the test signal used may need to be adapted.

### 6.3.12 Out-of-band signals in receive direction

**Requirement**

Any spurious out-of-band image signals in the frequency range from 4,6 kHz to 8 kHz measured selectively shall be lower than the in-band level measured with a reference signal. The minimum level difference between the reference signal level and the out-of-band image signal level shall be as given in Table 10.

<table>
<thead>
<tr>
<th>Frequency</th>
<th>Signal limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>4,6 kHz</td>
<td>35 dB</td>
</tr>
<tr>
<td>8 kHz</td>
<td>45 dB</td>
</tr>
</tbody>
</table>

*NOTE:* The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

**Measurement method**

Test setup is described in clause 6.2.

Measurement is operated at nominal value of volume control.

The signal used is an activation signal followed by a sine wave signal. For input signals at the frequencies 500 Hz, 1 000 Hz, 2 000 Hz and 3 150 Hz applied at the level of -16 dBm0, the level of spurious out-of-band image signals at frequencies up to 8 kHz is measured selectively at measurement point.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. Level of this activation signal shall be -16 dBm0.

### 6.3.13 Receive noise

**Requirement**

The noise level measured until 10 kHz shall not exceed -54 dBPa(A) at nominal setting of the volume control.

No peaks in the frequency domain higher than 10 dB above the average noise spectrum shall occur.

*NOTE:* For softphone fan noise should be avoided in order to fulfil this condition.

**Measurement method**

The test setup is described in clause 6.2.
The A-weighted noise level shall be measured at DRP of the artificial ear with the freefield equalization active. The noise level is measured until 10 kHz.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for activation. Level of this activation signal shall be -16 dBm0.

The noise shall be measured just after interrupting the activation signal.

Spectral peaks are measured in the frequency domain in the frequency range from 100 Hz to 3.4 kHz. The frequency spectrum of the idle channel noise is measured by a spectral analysis having a noise bandwidth of 8.79 Hz (determined using FFT 8k samples/48 kHz sampling rate with Hanning window or equivalent). The idle channel noise spectrum is stated in dB. A smoothed average idle channel noise spectrum is calculated by a moving average (arithmetic mean) 1/3rd octave wide across the idle noise channel spectrum stated in dB (linear average in dB of all FFT bins in the range from $2^{-\frac{1}{6}}f$ to $2^{\frac{1}{6}}f$). Peaks in the idle channel noise spectrum are compared against a smoothed average idle channel noise spectrum.

6.3.14 Double talk performance

6.3.14.1 General

During double talk the speech is mainly determined by 2 parameters: impairment caused by echo during double talk and level variation between single and double talk (attenuation range).

In order to guarantee sufficient quality under double talk conditions the Talker Echo Loudness Rating should be high and the attenuation inserted should be as low as possible. Terminals which do not allow double talk in any case should provide a good echo attenuation which is realized by a high attenuation range in this case.

The most important parameters determining the speech quality during double talk are (see Recommendations ITU-T P.340 [18] and P.502 [21]):

- Attenuation range in Send direction during double talk $A_{H,S,dt}$.
- Attenuation range in receive direction during double talk $A_{H,R,dt}$.
- Echo attenuation during double talk.

6.3.14.2 Attenuation range in send direction during double talk $A_{H,S,dt}$

Requirement

Based on the level variation in Send direction during double talk $A_{H,S,dt}$ the behaviour of the terminal can be classified according to Table 11.

<table>
<thead>
<tr>
<th>Category (according to Recommendation ITU-T P.340 [18])</th>
<th>1</th>
<th>2a</th>
<th>2b</th>
<th>2c</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_{H,S,dt}$ [dB]</td>
<td>≤ 3</td>
<td>≤ 6</td>
<td>≤ 9</td>
<td>≤ 12</td>
<td>&gt; 12</td>
</tr>
</tbody>
</table>

The terminal shall have full duplex capability (category 1).

The requirement applies with nominal setting of the volume control for nominal signal levels in send and receive directions as well as for the level combinations +6 dB (re. nominal level) in send/-6 dB (re. nominal level) in receive and +6 dB (re. nominal level) in receive/-6 dB (re. nominal level) in send. The requirement also applies for maximum setting of the volume control with nominal signal levels in send and receive directions.

In general Table 11 provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.
This measurement shall be done for the desktop hands free terminals and soft phones also with variable echo path.

**Measurement method**

Test setup is described in clause 6.2.

The long conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for conditioning the terminal, with the female speaker in the receive direction. The test signal to determine the attenuation range during double talk is the double talk speech sequence as defined in clause 7.3.5 of Recommendation ITU-T P.501 [20] as shown in Figure 18. The competing speaker is always inserted as the double talk sequence sdt(t) either in send or receive and is used for analysis.

![Double talk test sequence with overlapping speech sequences in send and receive direction](image)

**Figure 18: Double talk test sequence with overlapping speech sequences in send and receive direction**

The attenuation range during double talk is determined as described in Appendix III of Recommendation ITU-T P.502 [21]. The double talk performance is analysed for each word and sentence produced by the competing speaker. The requirement has to be met for each word and sentence produced by the competing speaker.

6.3.14.3 Attenuation range in receive direction during double talk $A_{H,R,dt}$

**Requirement**

Based on the level variation in receive direction during double talk $A_{H,R,dt}$ the behaviour of the terminal can be classified according to Table 12.

**Table 12**

<table>
<thead>
<tr>
<th>Category (according to Recommendation ITU-T P.340 [18])</th>
<th>1</th>
<th>2a</th>
<th>2b</th>
<th>2c</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td>$A_{H,R,dt}$ (dB)</td>
<td>≤ 3</td>
<td>≤ 5</td>
<td>≤ 8</td>
<td>≤ 10</td>
<td>&gt; 10</td>
</tr>
</tbody>
</table>

The terminal shall have full duplex capability (category 1).
The requirement applies with nominal setting of the volume control for nominal signal levels in send and receive directions as well as for the level combinations +6 dB (re. nominal level) in send/-6 dB (re. nominal level) in receive and +6 dB (re. nominal level) in receive/-6 dB (re. nominal level) in send. The requirement also applies for maximum setting of the volume control with nominal signal levels in send and receive directions.

In general Table 12 provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.

This measurement shall be done for the desktop hands free terminals and soft phones also with variable echo path.

**Measurement method**

Test setup is described in clause 6.2.

The long conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] shall be used for conditioning the terminal, with the female speaker in the receive direction. The test signal to determine the attenuation range during double talk is shown in Figure 18. A sequence of speech signals is used which is inserted in parallel in Send and receive direction. The test signals are synchronized in time at the acoustical interface. The delay of the test arrangement should be constant during the measurement.

The attenuation range during double talk is determined as described in Appendix III of Recommendation ITU-T P.502 [21]. The double talk performance is analysed for each word and sentence produced by the competing speaker. The requirement has to be met for each word and sentence produced by the competing speaker.

### 6.3.14.4 Detection of echo components during double talk

**Requirement**

"Echo Loss" (EL) is the echo suppression provided by the terminal measured at the electrical reference point. Under these conditions the requirements given in Table 13 are applicable (more information can be found in annex A of the Recommendation ITU-T P.340 [18]).

<table>
<thead>
<tr>
<th>Category (according to Recommendation ITU-T P.340 [18])</th>
<th>1</th>
<th>2a</th>
<th>2b</th>
<th>2c</th>
<th>3</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Full Duplex Capability</td>
<td>Partial Duplex Capability</td>
<td>No Duplex Capability</td>
<td></td>
<td></td>
</tr>
<tr>
<td><strong>Echo Loss [dB]</strong></td>
<td>≥ 27</td>
<td>≥ 23</td>
<td>≥ 17</td>
<td>≥ 11</td>
<td>&lt; 11</td>
</tr>
</tbody>
</table>

**NOTE:** The echo attenuation during double talk is based on the parameter Talker Echo Loudness Rating (TELRLR). It is assumed that the terminal at the opposite end of the connection provides nominal Loudness Rating (SLR + RLR = 10 dB).

This measurement shall be done for the desktop hands free terminals and soft phones also with variable echo path.

The terminal shall have full duplex capability (category 1).

The requirement applies with nominal setting of the volume control for nominal signal levels in send and receive directions as well as for the level combinations +6 dB (re. nominal level) in send/-6 dB (re. nominal level) in receive and +6 dB (re. nominal level) in receive/-6 dB (re. nominal level) in send. The requirement also applies for maximum setting of the volume control with nominal signal levels in send and receive directions.

**Measurement method**

Test setup is described in clause 6.2.

The double talk signal consists of a sequence of orthogonal signals which are realized by voice-like modulated sine waves spectrally shaped similar to speech. A detailed description can be found in Recommendation ITU-T P.501 [20].

The signals are fed simultaneously in Send and receive direction. The level in Send direction shall be -4.7 dBPa at the MRP (nominal level), the level in receive direction is -16 dBm0 at the electrical reference point (nominal level).
The settings for the signals are as follows.

### Table 14: Parameters of the two Test Signals for Double Talk Measurement based on AM-FM modulated sine waves

<table>

**NOTE:** Parameters of the Shaping Filter:

\( f \geq 250 \text{ Hz}: \text{Low Pass Filter, 5 dB/oct}. \)

The test signal is measured at the electrical reference point (Send direction). The measured signal consists of the double talk signal which was fed in by the artificial mouth and the echo signal. The echo signal is filtered by comb filter using mid-frequencies and bandwidth according to the signal components of the signal in receive direction (see Recommendation ITU-T P.501 [20]). The filter will suppress frequency components of the double talk signal.

In each frequency band which is used in receive direction the echo attenuation can be measured separately. The requirement for category 1 is fulfilled if in any frequency band the echo signal is either below the signal noise or below the required limit. If echo components are detectable, the classification is based on Table 13. The echo attenuation is to be achieved for each individual frequency band according to the different categories.

#### 6.3.14.5 Minimum activation level and sensitivity of double talk detection

For further study.

#### 6.3.15 Switching characteristics

##### 6.3.15.1 Note

**NOTE:** Additional requirements may be needed in order to further investigate the effect of NLP implementations on the users’ perception of speech quality.

##### 6.3.15.2 Activation in send direction

The activation in send direction is mainly determined by the built-up time \( T_{r,S,\text{min}} \) and the minimum activation level \( (L_{S,\text{min}}) \). The minimum activation level is the level required to remove the inserted attenuation in send direction during idle mode. The built-up time is determined for the test signal burst which is applied with the minimum activation level.

The activation level described in the following is always referred to the test signal level at the Mouth Reference Point (MRP).

**Requirements**

The minimum activation level \( L_{S,\text{min}} \) shall be \( \leq -20 \text{ dBPa} \).
The built-up time $T_{r,S,min}$ (measured with minimum activation level) should be $\leq 15$ ms.

**Measurement method**

Test setup is described in clause 6.2.

The test signal is the "short words for activation" sequence described in clause 7.3.4 of Recommendation ITU-T P.501 [20] with increasing level for each single word.

The settings of the test signal are as follows.

<table>
<thead>
<tr>
<th>Table 15</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Single word/ Pause Duration</strong></td>
</tr>
<tr>
<td>Single word to Determine Switching Characteristic in Send Direction</td>
</tr>
</tbody>
</table>

NOTE: The signal level is determined for each utterance individually according to Recommendation ITU-T P.56 [14].

It is assumed that the pause length of about 400 ms is longer than the hang-over time so that the test object is back to idle mode after each single word.

The level of the transmitted signal is measured at the electrical reference point. The test signal is filtered by the transfer function of the test object. The measured signal level is referred to the filtered test signal level and displayed vs. time. The levels are calculated from the time domain using an integration time of 5 ms.

The minimum activation level is determined from the single word which indicates the first activation of the test object. The time between the beginning of the single word and the complete activation of the test object is measured.

6.3.15.3 Silence suppression and comfort noise generation

For further study.

6.3.16 Background noise performance

6.3.16.1 Performance in send direction in the presence of background noise

**Requirement**

The level of comfort noise, if implemented, shall be within in a range of +2 dB and -5 dB compared to the original (transmitted) background noise. The noise level is calculated with psophometric weighting.

NOTE 1: It is advisable that the comfort noise matches the original signal as good as possible (from a perceptual point of view).

NOTE 2: Input for further specification necessary (e.g. on temporal matching).

The spectral difference between comfort noise and original (transmitted) background noise shall be within the mask given through straight lines between the breaking points on a logarithmic (frequency) - linear (dB sensitivity) scale as given in Table 16.
Table 16: Requirements for spectral adjustment of comfort noise (Mask)

</tr>
<tr>
<td>4 000 Hz</td>
<td>6 dB</td>
<td>-6 dB</td>
</tr>
</tbody>
</table>

NOTE: All sensitivity values are expressed in dB on an arbitrary scale.

**Measurement method**

Test setup is described in clause 6.2.

The background noise simulation as described in clause 6.2 is used.

First the background noise transmitted in send is recorded at the POI for a period of at least 20 s.

In a second step a test signal is applied in receive direction consisting of an initial pause of 10 s and a periodical repetition of the female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] in receive direction (duration 10 s) with nominal level to enable comfort noise injection simultaneously with the background noise. For the measurement the background noise sequence has to be started at the same point as it was started in the previous measurement.

The transmitted signal is recorded in Send direction at the POI.

The power density spectra measured in Send direction without far end speech simulation averaged between 10 s and 20 s is referred to the power density spectrum measured in Send direction determined during the period with far end speech simulation in receive direction averaged between 10 s and 20 s. Level and spectral differences between both power density spectra are analysed and compared to the requirements.

**6.3.16.2 Speech quality in the presence of background noise**

**Requirement**

Speech Quality for wideband systems can be tested based on ETSI EG 202 396-3 [i.2]. The test method is applicable for narrowband (100 Hz to 4 kHz) and wideband (100 Hz to 8 kHz) transmission systems. LQOn is used for narrowband systems.

For the background noises defined in clause 6.3, the following requirements apply:

- N-MOS-LQOn \( \geq 3,0 \).
- S-MOS-LQOn \( \geq 3,0 \).
- G-MOS-LQOn \( \geq 3,0 \).

NOTE: It is recommended to test the terminal performance with other types of background noises if the terminal is likely to be exposed to other noises than specified in clause 6.2.

**Measurement method**

The background noise simulation as described in clause 6.2 is used. The terminal is set-up as described in clause 6.2.

The background noise should be applied for at least 5 s in order to adapt noise reduction algorithms in advance the test.

The near end speech signal consists of 8 sentences of speech (2 male and 2 female talkers, 2 sentences each). Appropriate speech samples can be found in Recommendation ITU-T P.501 [20]. The preferred language is English since the objective method was validated with English language in narrowband. The test signal level is +1,3 dBPa at the MRP.

Three signals are required for the tests:

1) The clean speech signal is used as the undisturbed reference (see ETSI EG 202 396-3 [i.2]).
2) The speech plus undisturbed background noise signal is recorded at the terminal's microphone position using an omni directional measurement microphone with a linear frequency response between 50 Hz and 6 kHz.

3) The Send signal is recorded at the electrical reference point.

N-MOS-LQOn, S-MOS LQOn and G-MOS LQOn are calculated per sentence as described in ETSI EG 202 396-3 [i.2]. The resulting N-MOS-LQOn-, S-MOS-LQOn- and G-MOS-LQOn-values are averaged over all 8 sentences.

6.3.16.3 Quality of background noise transmission (with far end speech)

Requirements

The test is carried out applying a speech signal in receive direction. During and after the end of the speech signal the signal level in Send direction should not vary more than 10 dB (during transition to transmission of background noise without far end speech). The measurement is conducted for all types of background noise as defined in clause 6.2.

NOTE: The intention of this measurement is to detect impairments (modulations, switching and others) influencing the background noise transmitted from the terminal under test when a signal from the distant end (receiving side of the terminal under test) is present. Under these test conditions no modulation of the transmitted signal should occur. Modulation, switching or other type of impairments might be caused by an improper behaviour of a nonlinear processor working in conjunction with the echo canceller and erroneously switching or modulating the transmitted background noise.

Measurement method

Test setup is described in clause 6.2.

The background noises are generated as described in clause 6.2.

First the measurement is conducted without inserting the signal at the far end. At least 10 s of noise are analysed. The background signal level versus time is calculated using a time constant of 35 ms. This is the reference signal.

In a second step the same measurement is conducted but with inserting the speech signal at the far end. The exactly identical background noise signal is applied. The background noise signal shall start at the same point in time which was used for the measurement without far end signal. The background noise should be applied for at least 5 s in order to allow adaptation of the noise reduction algorithms. After at least 5 s a series of the female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [20] is applied in receive direction with duration of at least 10 s. The test signal level is -16 dBm0 at the electrical reference point.

The Send signal is recorded at the electrical reference point. The test signal level versus time is calculated using a time constant of 35 ms.

The level variation in Send direction is determined during the time interval when the speech signal is applied and after it stops. The level difference is determined from the difference of the recorded signal levels vs. time between reference signal and the signal measured with far end signal.

6.3.17 Quality of echo cancellation

6.3.17.1 Temporal echo effects

Requirement

This test is intended to verify that the system will maintain sufficient echo attenuation during single talk. The measured echo attenuation during single talk should not decrease by more than 6 dB from the maximum measured echo attenuation.

Measurement method

Test setup is described in clause 6.2.
The test signal consists of periodically repeated Composite Source Signal according to Recommendation ITU-T P.501 [20] with an average level of -5 dBm0 as well as an average level of -25 dBm0. The echo signal is analysed during a period of at least 2.8 s which represents 8 periods of the CS signal. The integration time for the level analysis shall be 35 ms, the analysis is referred to the level analysis of the reference signal.

The measurement result is displayed as attenuation vs. time. The exact synchronization between input and output signal has to be guaranteed.

The difference between the maximum attenuation and the minimum attenuation is measured.

NOTE 1: In addition tests with more speech like signals should be made, e.g. Recommendation ITU-T P.50 [13] to see time variant behaviour of EC. However for such tests the simple broadband attenuation based test principle as described above cannot be applied due to the time varying spectral content of the speech like signals.

NOTE 2: The analysis is conducted only during the active signal part, the pauses between the Composite Source Signals are not analysed. The analysis time is reduced by the integration time (35 ms) of the level analysis taking into account the exponential character of the integration time in any tolerance scheme.

NOTE 3: Care should be taken not to confuse noise or comfort noise with residual echo. In cases of doubt the measured echo signal should be compared to the residual noise signal measured under the same conditions without inserting the receive signal. If the level vs. time analysis leads to the identical result it can be assumed that no echo but just comfort noise is present.

6.3.17.2 Spectral echo attenuation

Requirement

The echo attenuation vs. frequency shall be below the tolerance mask given in Table 17.

<table>
<thead>
<tr>
<th>Frequency (Hz)</th>
<th>Limit (dB)</th>
</tr>
</thead>
<tbody>
<tr>
<td>100</td>
<td>-20</td>
</tr>
<tr>
<td>200</td>
<td>-30</td>
</tr>
<tr>
<td>300</td>
<td>-38</td>
</tr>
<tr>
<td>800</td>
<td>-34</td>
</tr>
<tr>
<td>1 500</td>
<td>-33</td>
</tr>
<tr>
<td>2 600</td>
<td>-24</td>
</tr>
<tr>
<td>4 000</td>
<td>-24</td>
</tr>
</tbody>
</table>

NOTE 1: All sensitivity values are expressed in dB on an arbitrary scale.

NOTE 2: The limit at intermediate frequencies lies on a straight line drawn between the given values on a log (frequency) - linear (dB) scale.

During the measurement it should be ensured that the measured signal is really the echo signal and not the Comfort Noise which possibly may be inserted in Send direction in order to mask the echo signal.

Measurement method

Test setup is described in clause 6.2.

Before the actual measurement a training sequence is fed in consisting of the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [20] is applied. The level of the training sequence shall be -16 dBm0.

The test signal is the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [20]. The measurement is carried out under steady-state conditions. The average test signal level shall be -16 dBm0, averaged over the complete test signal. The power density spectrum of the measured echo signal is referred to the power density spectrum of the original test signal. The analysis is conducted using FFT analysis with 8 k points (48 kHz sampling rate, Hanning window).

The spectral echo attenuation is analysed in the frequency domain in dB.
6.3.17.3 Occurrence of artefacts

For further study.

6.3.17.4 Variable echo path

Requirement

This test is intended to verify that the system will maintain sufficient echo attenuation during single talk with dynamic changing echo paths. The measured echo level over time during single talk should not be more than 10 dB above the minimum noise level during the measurement.

Measurement method

Test setup is described in clause 6.2.

As test signal the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [20] is used. The signal level shall be -10 dBm0. The terminal volume control is set to nominal RLR. The first 4 sentences of the test signal are used to allow full convergence of the echo canceller. The next 4 sentences (from 10,75 s to 22,5 s) are used for the analysis. The echo signal level is analysed over time The echo signal level is analysed for 11,75 s, using a time constant of 35 ms.

The measurement result is displayed as echo level versus time.

No level peak should be more than 10 dB above the minimum noise level during the measurement.

6.3.18 Variant impairments

6.3.18.1 Clock accuracy send

Requirement

The clock accuracy in send direction between the VoIP Terminal and the IP reference interface shall be less than 150 ppm under ideal network conditions.

NOTE: The clock accuracy does not cover all possible network configurations. Especially it is not sufficient for data transmission or distributed TDM PBX where synchronization is required.

Measurement method

A sequence of CS signals (active signal length = 250 ms) is repeated for 120 s in order to analyse clock accuracy and any other time-variant delay. The pause length between two CS bursts is 100 ms and 1,2 s after every fourth burst in order to simulate a speech pause, which may lead to buffer adjustments. The test signal level shall be -4,7 dBPa at the MRP.

A cross correlation analysis versus time is carried out over the whole 120 s sequence between the received and the original test signal. The duration of the measurement (120 s) is indicated on the x-axis, the result of the cross correlation analysis (delay) is plotted on the y-axis.

The resulting clock accuracy within an analysis time range of at least 60 s is calculated as follows:

\[
\text{clock accuracy [ppm]} = \frac{\text{delay change [s]}}{\text{analysis duration [s]}} \times 10^6
\]  

6.3.18.2 Clock accuracy receive

Requirement

The clock accuracy in receive direction between the IP reference interface and the VoIP Terminal shall be less than 150 ppm under ideal network conditions.
Measurement method
A sequence of CS signals (active signal length = 250 ms) is repeated for 120 s in order to analyse clock accuracy and any other time-variant delay. The pause length between two CS bursts is 100 ms and 1,2 s after every fourth burst in order to simulate a speech pause, which may lead to buffer adjustments. The test signal level at the IP reference interface shall be -16 dBm0.

A cross correlation analysis versus time is carried out over the whole 120 s sequence between the received and the original test signal. The duration of the measurement (120 s) is indicated on the x-axis, the result of the cross correlation analysis (delay) is plotted on the y-axis.

The resulting clock accuracy within an analysis time range of at least 60 s is calculated as follows:

\[
\text{clock accuracy [ppm]} = \frac{\text{delay change [s]}}{\text{analysis duration [s]}} \cdot 10^6
\]

6.3.18.3 Send packet delay variation

Requirement
The measured maximum delay variation of RTP packets in send direction of the VoIP terminal under test should be less than 1 ms.

NOTE: Any delay variation of RTP packets introduced in send direction will lead to potentially increased delay due to increased de-jitter buffer at the far end terminal.

Measurement method
The RTP data stream in send direction should be monitored with a tap or a switch providing a monitoring port, positioned at the location of the network impairment simulator (see clause 6.2). The test arrangement is according to clause 6.2.

The monitoring time should be 60 s. A signal like the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [20] is played back in send direction using a nominal level of -4,7 dBPa at the MRP. This speech signal is only necessary to make sure, RTP is played out, even in the case VAD is active.

The delay variation for each packet D(i) is evaluated according to IETF RFC 3550 [30]:

\[
d(i) = \Delta_{\text{eff}(i)} - \Delta_{\text{exp}(i)}
\]

\[
D(i) = (15 \times D(i-1) + |d(i)|)/16
\]

With:
- \(\Delta_{\text{exp}(i)}\) = the expected time between packet i and packet i-1; and
- \(\Delta_{\text{eff}(i)}\) = the effective time between packet i and packet i-1.

Maximum delay variation = MAX(D(i)).

6.3.19 Send and receive delay - round trip delay

The roundtrip delay of a VoIP terminal is defined as the sum of send and receive delays. In the following clauses the calculation of the requirements for send and receive delay are explained. For a telecommunication connection, only the roundtrip delay can be experienced. For this reason, also the requirement for VoIP terminals is given only for the roundtrip delay. As long as the measured roundtrip delay fulfils the requirements, send or receive delays may be above the theoretical requirements.

Requirement
It is recognized that the end to end delay should be as small as possible in order to ensure high quality of the communication.
The roundtrip delay of the VoIP terminal $T_{rd}$ (sum of receive and send delay) shall be less than 100 ms. (category B in Recommendation ITU-T P-1010 [29]). From the users’ perspective, a value less than 50 ms (category A in Recommendation ITU-T P-1010 [29]) is preferred.

NOTE 1: The limit for the roundtrip delay $T_{rd}$ of the VoIP terminal is derived from the sum of the send and receive delay limits.

NOTE 2: This requirement is based on the lowest possible delay values which can be expected under ideal network conditions. Caution should be exercised to ensure that the terminal is operated under optimum conditions in order to avoid adverse effects, e.g. network conditions, settings and memory effects of the terminal jitter buffer.

**Measurement method**

**Send direction**

The delay in send direction is measured from the MRP to POI. The delay measured in send direction is:

$$T_s + t_{system}.$$  \hspace{1cm} (5)

**Figure 19: Different blocks contributing to the delay in send direction**

The system delay $t_{system}$ is depending on the transmission method used and the network simulator. The delay $t_{system}$ shall be known.

1) For the measurements a Composite Source Signal (CSS) according to Recommendation ITU-T P.501 [20] is used. The pseudo random noise (pn)-part of the CSS has to be longer than the maximum expected delay. It is recommended to use a pn sequence of 16 k samples (with 48 kHz sampling rate). The test signal level is -4,7 dBPa at the MRP:

- The reference signal is the original signal (test signal).
- The setup of the loudspeaking/handsfree terminal is in correspondence to clause 6.2.

2) The delay is determined by cross-correlation analysis between the measured signal at the electrical access point and the original signal. The measurement is corrected by delays which are caused by the test equipment.

3) The delay is measured in ms and the maximum of the cross-correlation function is used for the determination.

**Receive direction**

The delay in receive direction is measured from POI to the Drum Reference Point (DRP). The delay measured in receive direction is:

$$T_r + t_{system}.$$  \hspace{1cm} (6)
The system delay $t_{system}$ is depending on the transmission system and on the network simulator used. The delay $t_{System}$ shall be known:

1) For the measurements a Composite Source Signal (CSS) according to Recommendation ITU-T P.501 [20] is used. The pseudo random noise (pn)-part of the CSS has to be longer than the maximum expected delay. It is recommended to use a pn sequence of 16 k samples (with 48 kHz sampling rate). The test signal level is -16 dBm0 at the electrical interface (POI):
   - The reference signal is the original signal (test signal).

2) The test arrangement is according to clause 6.2.

3) The delay is determined by cross-correlation analysis between the measured signal at the DRP and the original signal. The measurement is corrected by delays which are caused by the test equipment.

4) The delay is measured in ms and the maximum of the cross-correlation function is used for the determination.

NOTE 3: It is not necessary to know the delays $T_s$, $T_r$ and $t_{system}$ per direction. The roundtrip delay of the terminal is the sum of send and receive delays minus the roundtrip delay of the measurement equipment and (if applicable) the network.

6.4 Codec specific requirements

6.4.1 Objective listening speech quality MOS-LQO in send direction

The listening speech quality tests are conducted under clean network conditions.

Requirements

The requirements for the listening speech quality are as follows.

<table>
<thead>
<tr>
<th>Speech coder</th>
<th>MOS-LQON (P.863 or TOSQA 2001)</th>
<th>MOS-LQOM (TOSQA 2001)</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>GSM EFR [2] and AMR @ 12.2 kbit/s [3]</td>
<td>(ffs)</td>
<td>(ffs)</td>
</tr>
<tr>
<td>Recommendation ITU-T G.729.1 @ 8 kbit/s [11]</td>
<td>(ffs)</td>
<td>(ffs)</td>
</tr>
</tbody>
</table>

NOTE 1: In narrowband acoustics, Recommendation ITU-T P.863 [27] is recommending using the fullband mode with a narrowband reference signal, resulting in a prediction on the narrowband scale.
NOTE 2: Not sufficient experience is available so far with Recommendation ITU-T P.863 [27] and TOSQA 2001 (ETSI EG 201 377-1 [i.4]) for measuring handsfree terminals. Therefore the numbers for MOS-LQOM and MOS-LQON are for further study.

Measurement method

Objective listening speech quality is measured using Recommendation ITU-T P.863 [27] in fullband mode.

The test signal to be used for the measurements shall be 4 sentence pairs (male/female) fulfilling the requirements of Recommendation ITU-T P.863.1 [26]. The 4 sentence pairs are taken from Recommendation ITU-T P.501 [20]. It shall be stated, which sentence pairs were used. The test signal level is averaged over all sentence pairs (4 sentence pairs). The measurement is done 4 times, every time using another pair of the speech sentences. The result of the measurement is the averaged value of all 4 measurements.

NOTE 4: An alternative test method is TOSQA 2001 (ETSI EG 201 377-1 [i.4]). With TOSQA, terminals used in narrowband mode only should be measured based on MOS-LQON. Terminals used in narrowband and wideband mode should be measured based on MOS-LQOM.

6.4.2 Objective listening speech quality MOS-LQO in receive direction

The listening speech quality tests are conducted under clean network conditions as well as with network impairments simulated. In addition to the listening speech quality tests the delay is measured.

Requirements

The requirements for the listening speech quality and the delay under clean network conditions are as follows.

<table>
<thead>
<tr>
<th>Speech coder</th>
<th>MOS-LQON (P.863 or TOSQA 2001)</th>
<th>MOS-LQOM (TOSQA 2001)</th>

<td>(ffs)</td>
<td>(ffs)</td>
</tr>
</tbody>
</table>

NOTE 1: In narrowband acoustics, Recommendation ITU-T P.863 [27] is recommending using the fullband mode with a narrowband reference signal, resulting in a prediction on the narrowband scale.

NOTE 2: Not sufficient experience is available so far with Recommendation ITU-T P.863 [27] and TOSQA 2001 (ETSI EG 201 377-1 [i.4]) for measuring handsfree terminals. Therefore the numbers for MOS-LQOM and MOS-LQON are for further study.

The requirements for the listening speech quality and the delay under impaired network conditions are as follows.

The roundtrip delay of the VoIP terminal $T_{rd}$ (sum of receive and send delay) shall be less than delay category B. From the users’ perspective, a value less than delay category A is preferred (for this, $T_{rd, clean}$ needs to fulfil the requirement for delay category A in clause 6.3.19).

NOTE 4: The delay requirements for conditions with network impairments for delay category A are based on the measured roundtrip delay of the terminal in the absence of network impairments $T_{rd clean}$ (see clause 6.3.19). A small additional tolerance takes into account the variable behaviour of the delay.

**Measurement method**

Objective listening speech quality is measured using Recommendation ITU-T P.863 [27] in fullband mode.

The test signal to be used for the measurements shall be 4 sentence pairs (male/female) fulfilling the requirements of Recommendation ITU-T P.863.1 [26]. The 4 sentence pairs are taken from Recommendation ITU-T P.501 [20]. It shall be stated, which sentence pairs were used. The test signal level is averaged over all sentence pairs (4 sentence pairs). The measurement is done 4 times, every time using another pair of the speech sentences. The result of the measurement is the averaged value of all 4 measurements.

NOTE 5: An alternative test method is TOSQA 2001 (ETSI EG 201 377-1 [i.4]). With TOSQA, terminals used in narrowband mode only should be measured based on MOS-LQON. Terminals used in narrowband and wideband mode should be measured based on MOS-LQOM.

For the performance tests with network impairments the following settings are used.

</tr>
</tbody>
</table>

**NOTE 1:** See annex D of ETSI ES 202 737 [28].

**NOTE 2:** VAD on, all other conditions (1 to 5) tested with VAD off.

**NOTE 3:** For some network emulation tools, it is necessary to introduce a constant delay to offer the possibility to generate a delay variation distribution. This delay has to be subtracted from the measured delay before interpreting the results.

**NOTE 4:** The settings are derived from the ones used in the ETSI Plugtest VoIP speech quality test events.

**NOTE 5:** When running tests with the conditions in row, it may be necessary to make one call per condition to avoid the influence of the order of the conditions to the results.

### 6.4.3 Quality of jitter buffer adjustment

#### Requirements

The speech quality during and after inserted IP delay variation shall be as follows.

#### Table 24: Requirements for variant network impairments

<table>
<thead>
<tr>
<th>Codec</th>
<th>MOS-LQON</th>
</tr>
</thead>
<tbody>
<tr>
<td>G.711</td>
<td>&gt; 3.9</td>
</tr>
<tr>
<td>G.729</td>
<td>&gt; 3.4</td>
</tr>
<tr>
<td>G.723.1</td>
<td>&gt; 3.1</td>
</tr>
</tbody>
</table>

The delay measured 20 s after ending of the IP delay variation shall be maximum 10 ms higher than the delay measured before the IP delay variation.

#### Measurement method

The test signal consists of a CSS-signal, followed by 5 times the same speech sentence, fulfilling the requirements of Recommendation ITU-T P.863.1 [26], then again a CSS signal (20 s after the IP delay variation stops). This test is done 8 times with 8 single sentences taken from 4 sentence pairs from Recommendation ITU-T P.501 [20]. The speech signal level is averaged over all (original) sentences (8 sentences) used.

**NOTE 1:** The 8 sentences used consist of the 8 single sentences taken from the 4 sentence pairs used in clauses 6.4.1 and 6.4.2.

**NOTE 2:** For every new measurement a new call has to be setup to start with an initial delay. Depending on the algorithm used in the variable jitter buffer (e.g. jitter buffer starting with a high fill size), it may be necessary to let some time pass under clean conditions until the measurement is started.

The first CSS signal is used to measure the delay prior to the IP impairment (in clean network conditions). The second CSS signal is used to measure the delay 20 s after the IP impairment stops. The difference of the two delays is the measurement result for the variation of the jitter buffer per measurement. The overall result is the average of all 8 measurements.

The first sentence (during which IPDV of 50 ms is applied) is used to measure the speech quality during jitter buffer adaptation (low to high). MOS-LQON of the first sentence is measured using Recommendation ITU-T P.863 [27] in fullband mode with a narrowband reference signal. The overall result is the average MOS-LQON of the 8 measurements.
The second to the fifth sentence (every 5 s a sentence) are used to measure the speech quality during jitter buffer adaption (high to low). MOS-LQON is measured using Recommendation ITU-T P.863 [27] in fullband mode with a narrowband reference signal for each of these four sentences. The minimum MOS-LQON of these four sentences is used for the averaging over all 8 measurements. The overall result for the speech quality during jitter buffer adaption (high to low) is the average of the minimum MOS-LQON-value of the 8 measurements.

**Figure 21: Test Sequence to measure quality of Jitter buffer adjustment (with 1 of 10 sentences)**

The IP impairment consists of additional packet delay (IPDV) up to 50 ms, during maximum 1 s. The impairment can be in form of jitter, but also with only some single packets delayed. An example for the impairment can be found in annex B of ETSI ES 202 737 [28].
Annex A (informative): Processing delays in VoIP terminals

This annex gives some elements about delays generated in VoIP terminals. At first, only wired terminals are considered. These terminals could be schematized as shown in Figure A.1.

![Figure A.1: Synoptic of the different functions implemented in a VoIP terminal](image)

The implemented functions in the Send part of the terminal are:

- The analogue-digital conversion.
- The encoding.
- The packetization.
- The interfacing with the network.

The implemented functions in the receive part of the terminal are:

- The interfacing with the network.
- The depacketization.
- The buffering.
- The decoding.
- The digital-analogue conversion.

Each function's contribution to the processing delay characterizing VoIP terminals is examined.

On the Send part of the terminal, the network interface operates the transfer of digital data from IP stack to IP network. At the reception, the network interface operates the transfer of digital data from IP network to IP stack. The network interface has a low contribution to the delay. The contribution is estimated at less than 2 ms per transmission way (Send and receive direction).

The packetization represents the transfer of the audio frames through the IP stack, from the telephony applicative part of the terminal to the transmission network. The packetization consists in adding specific headers (associated to different protocols) to audio frames. The delay associated to the packetization is considered as no significant and included into encoding time.

Encoding corresponds to the compression of the speech signal. The delay associated to the encoding process depends on the implemented codec and the payload's length (number of audio frames) inserted into each IP packet. On the Send part of the terminal, encoding is the main contribution to the processing delay. The delay can strongly change according to the codec and the payload's length.

Analogue to digital conversion consists in transforming speech signal from analogue to digital format. The processing delay associated to the conversion is considered as no significant.

Digital to analogue conversion consists in transforming speech signal from digital to analogue format. As analogue to digital conversion, the processing delay associated to digital to analogue conversion is considered as not significant.
The depacketization represents the transfer of the audio frames through the IP stack, from transmission network to the telephony applicative part of the terminal. The depacketization consists in tacking off the headers associated to protocols to get back audio frames after transmission. The delay associated to the depacketization is considered as no significant and included into the decoding processing time.

The first role of the jitter buffer is to ensure synchronization between Send and receive terminals. This synchronization is carried out by buffering the audio frames received from the IP stack before sending them to the decoder. The second role of the jitter buffer is to smooth a possible variation of the transmission time. If synchronization of Send and receive terminals requires a minimum size of buffer, smoothing transmission delay variation requires a buffer size depending on jitter produced by the network. High variations of transmission time involve an important size of the buffer to smooth jitter. Jitter buffers can be implemented either as buffer with static size(s) (several sizes are possible) or as dynamic buffer. In the last case, size management is carried out according to QoS present on the network interface. Jitter buffer is the main contribution to the processing time on the reception part of VoIP terminal.

Decoding corresponds to the rebuilding of speech signal from receive audio frames. The delay associated to decoding depends on the codec implemented. Decoding contributes in a significant way to the processing time on the reception part of VoIP terminal.

Table A.1 presents the processing times of VoIP terminals for different codecs and IP packet payload's lengths.

In this table, x1, x2, x3, x4, y5, x6 and x7 represent the encoding delays according to selected codec. In the same way, y1, y2, y3, y4, y5, y6 and y7 represent the decoding delays according to selected codec.

According to selected codec and payload's length, columns 5 and 6 show overall encoding and decoding delays respectively. Overall encoding time takes into account algorithm, encoding and packetization delays. Overall decoding time takes into account algorithm, decoding and depacketization delays.

Column 7 shows for each codec and payload's length the real time condition. It stands for the maximum duration to encode and decode at the same time. IP terminals have to meet this requirement.

Column 10 shows the minimum delay induced by the jitter buffer. To ensure a correct running of the VoIP terminal, the minimal size of jitter buffer has to correspond to the IP packet payload's length. Furthermore, a double buffering operation induces 10 additional ms in the overall jitter buffer processing.

Column 12 shows the minimum end-to-end delay induced by two terminals connected to a "perfect" network (i.e. with no jitter, no packet loss and with a null transmission delay), with real time condition at the lower limit (i.e. no significant encoding and decoding times).

Column 13 shows the minimum end-to-end delay induced by two terminals connected to a "perfect" network (i.e. with no jitter, no packet loss and with a null transmission delay), with real time condition at the upper limit (i.e. encoding + decoding times very close to the payload size).
