Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://webapp.etsi.org/IPR/home.asp>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This ETSI Standard (ES) has been produced by ETSI Technical Committee Speech and multimedia Transmission Quality (STQ).

Introduction

Traditionally, the analogue and digital telephones were interfacing switched-circuit 64 kbit/s PCM networks. With the fast growth of IP networks, terminals directly interfacing packet-switched networks (VoIP) are being rapidly introduced. Such IP network edge devices may include specifically designed IP phones, soft phones or other devices connected to the IP based networks and providing telephony service. Since the IP networks will be in many cases interworking with the traditional PSTN and private networks, many of the basic transmission requirements have to be harmonized with specifications for traditional digital terminals. However, due to the unique characteristics of the IP networks including packet loss, delay, etc. new performance specification, as well as appropriate measuring methods, will have to be developed. Terminals are getting increasingly complex. Advanced signal processing is used to address the IP specific issues. Also, the VoIP terminals may use other than 64 kbit/s PCM (ITU-T Recommendation G.711 [7]) speech algorithms.

The present document will provide speech transmission performance requirements for narrowband VoIP loudspeaking and hands-free terminals.

NOTE: Requirement limits are given in tables, the associated curve when provided is given for illustration.

1 Scope

The present document will provide speech transmission performance requirements for narrowband VoIP loudspeaking and hands-free terminals; it addresses all types of IP based terminals, including wireless, softphones and group audio terminals.

In contrast to other standards which define minimum performance requirements it is the intention of the present document to specify terminal equipment requirements which enable manufacturers and service providers to enable good quality end-to-end speech performance as perceived by the user.

In addition to basic testing procedures, the present document describes advanced testing procedures taking into account further quality parameters as perceived by the user.

NOTE: The present document does not concern headset terminals.

2 References

References are either specific (identified by date of publication and/or edition number or version number) or non-specific.

- For a specific reference, subsequent revisions do not apply.
- Non-specific reference may be made only to a complete document or a part thereof and only in the following cases:
 - if it is accepted that it will be possible to use all future changes of the referenced document for the purposes of the referring document;
 - for informative references.

Referenced documents which are not found to be publicly available in the expected location might be found at <http://docbox.etsi.org/Reference>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication ETSI cannot guarantee their long term validity.

2.1 Normative references

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

artificial ear: device for the calibration of earphones incorporating an acoustic coupler and a calibrated microphone for the measurement of the sound pressure and having an overall acoustic impedance similar to that of the median adult human ear over a given frequency band

codec: combination of an analogue-to-digital encoder and a digital-to-analogue decoder operating in opposite directions of transmission in the same equipment

ear-Drum Reference Point (DRP): point located at the end of the ear canal, corresponding to the ear-drum position

freefield equalization: artificial head is equalized in such a way that for frontal sound incidence in anechoic conditions the frequency response of the artificial head is flat

freefield reference point: point located in the free sound field, at least in 1,5 m distance from a sound source radiating in free air (in case of a head and torso simulator [HATS] in the centre of the artificial head with no artificial head present)

group audio terminal: handsfree terminal primarily designed for use by several users which will not be equipped with a handset

handsfree telephony terminal: telephony terminal using a loudspeaker associated with an amplifier as a telephone receiver and which can be used without a handset

HATS Hands-Free Reference Point (HATS HFRP): corresponds to a reference point "n" from ITU-T Recommendation P.58 [14]: "n" is one of the points numbered from 11 to 17 and defined in table 6a of ITU-T Recommendation P.58 [14] (coordinates of far field front point)

NOTE: The HATS HFRP depends on the location(s) of the microphones of the terminal under test: the appropriate axis lip-ring/HATS HFRP is to be as close as possible to the axis lip-ring/HFT microphone under test.

Head And Torso Simulator (HATS) for telephonometry: manikin extending downward from the top of the head to the waist, designed to simulate the sound pick-up characteristics and the acoustic diffraction produced by a median human adult and to reproduce the acoustic field generated by the human mouth

loudspeaking function: function of a handset telephone using a loudspeaker associated with an amplifier as a telephone receiver

Mouth Reference Point (MRP): is located on axis and 25 mm in front of the lip plane of a mouth simulator

nominal setting of the volume control: setting which is closest to the nominal RLR

softphone: speech communication system based upon a computer

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

CSS	Composite Source Signal
DRP	ear Drum Reference Point
EL	Echo Loss
HATS	Head And Torso Simulator
HFRP	Hands Free Reference Point
LAN	Local Area Network
L_E	Earphone coupling Loss

MOS-LQOy Mean Opinion Score - Listening Quality Objective

NOTE: See ITU-T Recommendation P.800.1 [24].

MRP	Mouth Reference Point
NLP	Non Linear Processor
PCM	Pulse Code Modulation
PLC	Packet Loss Concealment
PSTN	Public Switched Telephone Network
QoS	Quality of Service
RLR	Receive Loudness Rating
RLRmax	Receive Loudness Rating corresponding to the maximum setting of the volume control
RLRmin	Receive Loudness Rating corresponding to the minimum setting of the volume control
SLR	Send Loudness Rating
TCLw	Terminal Coupling Loss (weighted)
TCN	Trace Control for Netem

4 General considerations

4.1 Default Coding Algorithm

VoIP terminals shall support the coding algorithm according to ITU-T Recommendation G.711 [7] (both μ -law and A-law). VoIP terminals may support other coding algorithms.

NOTE: Packet Loss Concealment as defined in e.g. appendix I of ITU-T Recommendation G.711 [7] should be used.

4.2 End-to-end considerations

In order to achieve a desired end-to-end speech transmission performance (mouth-to-ear) it is recommended that general rules of transmission planning tasks are carried out with the E-model taking into account that E model does not directly address handsfree or loudspeaking terminals; this includes the a-priori determination of the desired category of speech transmission quality as defined in ITU-T Recommendation G.109 [4].

While, in general, the transmission characteristics of single circuit-oriented network elements, such as switches or terminals can be assumed to have a single input value for the planning tasks of ITU-T Recommendation G.108 [3] this approach is not applicable in packet based systems and thus there is a need for the transmission planner's specific attention.

In particular the decision as to which delay measured according to the present Standard is acceptable or representative for the specific configuration is the responsibility of the individual transmission planner.

ITU-T Recommendation G.108 [3] provides further guidance on this important issue.

The following optimum terminal parameters from a users' perspective need to be considered:

- Minimized delay in send and receive direction.
- Optimum loudness Rating (RLR, SLR).
- Compensation for network delay variation.
- Packet loss recovery performance.
- Maximized terminal coupling loss.
- Some more basic (I-ETS 300 245-3 [1]) parameters are applicable, if ITU-T Recommendation G.711 [7] is used.

4.3 Parameters to be investigated

4.3.1 Basic parameters

The basic parameters are given in ETS 300 245-3 [1], ITU-T Recommendation P.342 [18] and ITU-T Recommendation P.340 [17].

4.3.2 Further Parameters with respect to Speech Processing Devices

For VoIP terminals that contain non-linear speech processing devices, the following parameters require additional attention in the context of the present document.

The measurements for further parameters with respect to speech processing devices which are a novelty to terminal requirement standards, have been successfully used in TR 102 648-1 [i.1].

- Objective evaluation of speech quality for VoIP terminals.
- Minimum activation level and sensitivity in Receive direction.
- Automatic Level Control in Receive.
- Double Talk Performance.
- Minimum activation level and sensitivity of double talk detection.
- Switching characteristics.
- Quality of echo cancellation.
- Variant Impairments; Network dependant.
- Etc.

5 Test equipment

5.1 IP half channel measurement adaptor

The IP half channel measurement adaptor is described in EG 202 425 [i.3].

5.2 Environmental conditions for tests

The following conditions shall apply for the testing environment:

- a) Ambient temperature: 15 °C to 35 °C (inclusive).
- b) Relative humidity: 5 % to 85 %.
- c) Air pressure: 86 kPa to 106 kPa (860 mbar to 1 060 mbar).

5.3 Accuracy of measurements and test signal generation

Unless specified otherwise, the accuracy of measurements made by test equipment shall be equal to or better than:

Table 1: Measurement Accuracy

Item	Accuracy
Electrical signal level	$\pm 0,2$ dB for levels ≥ -50 dBV $\pm 0,4$ dB for levels < -50 dBV
Sound pressure	$\pm 0,7$ dB
Frequency	$\pm 0,2$ %
Time	$\pm 0,2$ %
Application force	± 2 Newton

Unless specified otherwise, the accuracy of the signals generated by the test equipment shall be better than:

Table 2: Accuracy of test signal generation

Quantity	Accuracy
Sound pressure level at Mouth Reference Point (MRP)	± 3 dB for frequencies from 100 Hz to 200 Hz ± 1 dB for frequencies from 200 Hz to 4 000 Hz ± 3 dB for frequencies from 4 000 Hz to 8 000 Hz
Electrical excitation levels	$\pm 0,4$ dB across the whole frequency range
Frequency generation	± 2 % (see note)
Time	$\pm 0,2$ %
Specified component values	± 1 %
NOTE:	This tolerance may be used to avoid measurements at critical frequencies, e.g. those due to sampling operations within the terminal under test.

For terminal equipment which is directly powered from the mains supply, all tests shall be carried out within ± 5 % of the rated voltage of that supply. If the equipment is powered by other means and those means are not supplied as part of the apparatus, all tests shall be carried out within the power supply limit declared by the supplier. If the power supply is a.c., the test shall be conducted within ± 4 % of the rated frequency.

5.4 Network impairment simulation

At least one set of requirements is based on the assumption of an error free packet network, and at least one other set of requirements is based on a defined simulated loss of performance of the packet network.

An appropriate network simulator has to be used, for example NISTnet (<http://snad.ncsl.nist.gov/itg/nistnet/>) or Netem.

Based on the positive experience, STQ have made during the ETSI Speech Quality Test Events with "NIST Net" this will be taken as a basis to express and describe the variations of packet network parameters for the appropriate tests.

Here is a brief blurb about NIST Net:

- The NIST Net network emulator is a general-purpose tool for emulating performance dynamics in IP networks. The tool is designed to allow controlled, reproducible experiments with network performance sensitive/adaptive applications and control protocols in a simple laboratory setting. By operating at the IP level, NIST Net can emulate the critical end-to-end performance characteristics imposed by various wide area network situations (e.g. congestion loss) or by various underlying subnetwork technologies (e.g. asymmetric bandwidth situations of xDSL and cable modems).

- NIST Net is implemented as a kernel module extension to the Linux operating system and an X Window System-based user interface application. In use, the tool allows an inexpensive PC-based router to emulate numerous complex performance scenarios, including: tunable packet delay distributions, congestion and background loss, bandwidth limitation, and packet reordering / duplication. The X interface allows the user to select and monitor specific traffic streams passing through the router and to apply selected performance "effects" to the IP packets of the stream. In addition to the interactive interface, NIST Net can be driven by traces produced from measurements of actual network conditions. NIST Net also provides support for user defined packet handlers to be added to the system. Examples of the use of such packet handlers include: time stamping/data collection, interception and diversion of selected flows, generation of protocol responses from emulated clients.

The key points of Netem can be summarized as follows:

- Netem is nowadays part of most Linux distributions, it only has to be switched on, when compiling a kernel. With Netem, there are the same possibilities as with nistnet, there can be generated loss, duplication, delay and jitter (and the distribution can be chosen during runtime). Netem can be run on a Linux-PC running as a bridge or a router (Nistnet only runs on routers).
- With an amendment of Netem, Trace Control for Netem (TCN) which was developed by ETH Zurich, it is even possible, to control the behaviour of single packets via a trace file. So it is for example possible to generate a single packet loss, or a specific delay pattern. This amendment is planned to be included in new Linux kernels, nowadays it is available as a patch to a specific kernel and to the iproute2 tool (iproute2 contains Netem).
- It is not advised to define specific distortion patterns for testing in standards, because it will be easy to adapt devices to these patterns (as it is already done for test signals). But if a pattern is unknown to a manufacturer, the same pattern can be used by a test lab for different devices and gives comparable results. It is also possible to take a trace of Nistnet distortions, generate a file out of this and playback the exact same distortions with Netem.

5.5 Acoustic environment

In general two possible approaches need to be taken into account: either room noise and background noise are an inherent part of the test environment or room noise and background noise shall be eliminated to such an extent that their influence on the test results can be neglected.

Unless stated otherwise measurements shall be conducted under quiet and "anechoic" conditions. Depending on the distance of the transducers from mouth and ear a quiet office room may be sufficient e.g. for handsets where artificial mouth and artificial ear are located close to the acoustical transducers. But this is not applicable for handsfree and loudspeaking terminals.

In cases where real or simulated background noise is used as part of the testing environment, the original background noise must not be noticeably influenced by the acoustical properties of the room.

In all cases where the performance of acoustic echo cancellers shall be tested, a realistic room, which represents the typical user environment for the terminal shall be used.

In case where an anechoic room is not available the test room has to be an acoustically treated room with few reflections and a low noise level.

Considering this, the test laboratory, in the case where its test room does not conform to anechoic conditions as given in ITU-T Recommendation P.342 [18], has to present difference in results for measurements due to its test room.

6 Test setup

In order to use a compatible test system for all types of speech terminals a HATS (Head and Torso Simulator) will be used instead of free field microphone (for receive measurement) and artificial mouth (for Send measurement). HATS is described in ITU-T Recommendation P.58 [14].

The preferred way of testing a terminal is to connect it to a network simulator with exact defined settings and access points. The test sequences are fed in either electrically, using a reference codec or using the direct signal processing approach or acoustically using ITU-T specified devices.

When, a coder with variable bite rate is used, we should adopt, for testing terminal electroacoustical parameters, the bit rate recognized as giving the best characteristics is selected, e.g.:

- TS 126 171 [2]: 12,2 kbit/s.

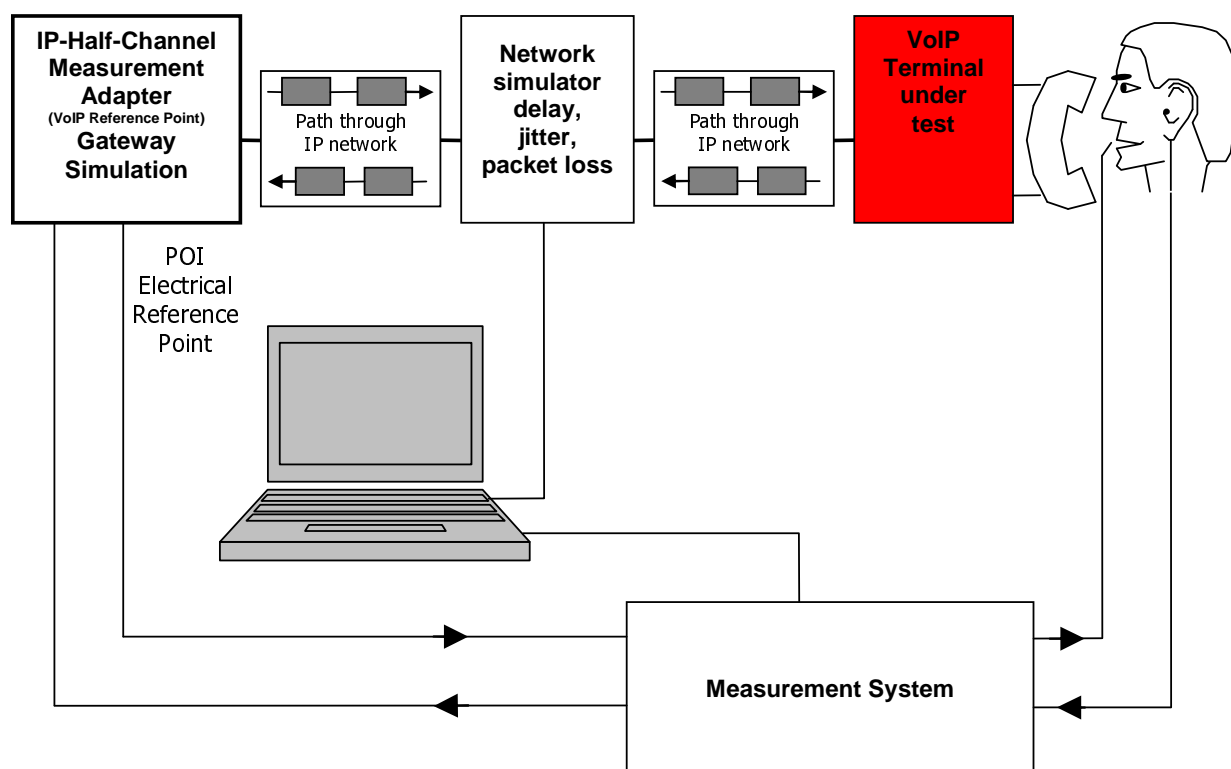

Figure 1: Half channel terminal measurement

6.1 Setup for terminal

6.1.1 Hands-free measurements

The ear used for measurement shall be indicated in the test report.

Desktop operated hands-free terminal

For HATS test equipment, the definition of hands-free terminals and setups for hands-free terminal can be found in ITU-T Recommendation P.581 [21].

Figure 2: Position for test of desktop hands free terminal side view

Figure 3: Position for test of desktop hands free terminal top sight

Handheld hands-free terminal

It should be placed in according to figure 4. The HATS should be positioned so that the HATS Reference Point is at a distance d_{HF} from the centre point of the visual display of the Mobile Station. The distance d_{HF} is specified by the manufacturer. A vertical angle θ_{HF} may be specified by the manufacturer.

Figure 4: Configuration of Hand-Held loudspeaker relative to the HATS side view

The HATS reference point should be located at a distance d_{HF} from the centre of the visual display of the Mobile Station. The distance d_{HF} is specified by the manufacturer, $d_{HFR}=d_{HF}$, $d_{HFS}=d_{HF}-d_{EM}$, where d_{HFR} is the distance for receive measurement, d_{HFS} is the distance for Send measurement, and d_{EM} is the distance from ERP to MRP.

When no operating distance is specified by manufacturer, value for d_{HFR} will be 30 cm. A calculation of d_{EM} for HATS gives 12 cm.

A value of 42 cm will be taken for d_{HF} .

Softphone (computer-based terminals)

Two types of softphones are to be considered:

- Type 1 is to be used as a desktop type (e.g. notebook).
- Type 2 is to be used as a handheld type (e.g. PDA).

When manufacturer gives conditions of use, they will apply for test.

If no other requirement is given by manufacturer softphone will be positioned according to the following conditions:

Softphone including speakers and microphone

Figure 5: Configuration of softphone relative to the HATS side view

Figure 6: Configuration of softphone relative to the HATS top sight

Softphone with separate speakers

When separate loudspeakers are used, system will be positioned as in figure 7.

Figure 7: Configuration of softphone using external speakers relative to the HATS top sight

When external microphone and speakers are used, system will be positioned as in figure 8.

Figure 8: Configuration of softphone using external speakers and microphone relative to the HATS top sight

Group audio terminal

When manufacturer gives conditions of use, they will apply for test.

When no requirement from manufacturer is given, the following conditions will be used by test laboratory.

Measurement will be conducted by using a HATS test equipment.

The following test position will be used.

Figure 9: Configuration of group audio terminal relative to the HATS side view

Figure 10: Configuration of group audio terminal relative to the HATS top sight

NOTE: In case of special casing where those conditions are not realistic, test laboratory can use a different position more representative of real use. The conditions of test will be given in the test report.

6.1.2 Measurements in loudspeaking mode

For those measurements HATS will be used.

It will be positioned as defined in clause 6.1.1 measurement will be performed on one ear and handset will be placed on the other ear. The ear used for measurement will be specified in test report.

NOTE: Only desktop terminals are concerned by loudspeaking measurement.

6.2 Test signal levels

6.2.1 Send

Unless specified otherwise, the test signal level shall be -4,7 dBPa at the MRP.

The following procedure shall be used to perform the calibration of the artificial mouth of the HATS:

- The input signal from the artificial mouth is first calibrated under free-field conditions at the MRP. The total level on the frequency range is set to -4,7 dBPa.
- The spectrum at MRP is recorded.
- Then the level is adjusted to the level given further in this text (depending of type of terminal tested (for example -24,3 dBPa at 30 cm for handheld terminal)).
- The level at MRP (measured in third octave bands) adjusted at the first step (with total level of -4,7 dBPa) is used as the reference for Send characteristics.

The test setup shall be in conformance with, figure 11 but, depending on the type of terminal, the appropriate distance and level will be used. When using this calibration method, send sensitivity must be calculated as follows:

- $S_{mJ} = 20 \log V_s - 20 \log PMRP$

where:

- V_s is the measured voltage across the appropriate termination (unless stated otherwise, a 600 Ω termination).

PMRP is the applied sound pressure at the MRP during the first step of calibration.

NOTE: Reason for this procedure of calibration in two steps is to take into account the different variation of signal with distance by using different implementations of HATS.

Figure 11: Calibration at HFRP

The distance used for level calibration corresponds to the following values:

- Desktop terminal: 50 cm and level to adjust - 28,7 dBPa.
- Handheld terminal: 30 cm with - 24,3 dBPa.
- Softphone: 36 cm with - 25,8 dBPa.
- Group audio terminal: 85 cm with - 33,3 dBPa.

6.2.2 Receive

Unless specified otherwise, the applied test signal level at the digital input shall be -16 dBm0.

All measurement values produced by HATS are intended to be free-field equalized.

6.3 Setup of background noise simulation

A setup for simulating realistic background noises in a lab-type environment is described in EG 202 396-1 [i.2].

The general procedure for setup a background noise simulation arrangement is described in EG 202 396-1 [i.2]. The EG 202 396-1 [i.2] contains a description of the recording arrangement for realistic background noises, a description of the setup for a loudspeaker arrangement suitable to simulate a background noise field in a lab-type environment and a database of realistic background noises, which can be used for testing the terminal performance with a variety of different background noises.

The principle loudspeaker setup for the simulation arrangement is shown in figure 12.

Figure 12: Loudspeaker arrangement for background noise simulation

The equalization and calibration procedure for the setup is described in detail in EG 202 396-1 [i.2]. If not stated otherwise this setup is used in all measurements where background noise simulation is required. The following noises of EG 202 396-1 [i.2] shall be used:

Recording in pub	Pub_Noise_binaural	30 s	L: 77,8 dB(A) R: 78,9 dB(A)	binaural
Recording at sales counter	Cafeteria_Noise_binaural	30 s	L: 68,4 dB(A) R: 67,3 dB(A)	binaural
Recording in business office	Work_Noise_Office_Callcenter_binaural	30 s	L: 56,6 dB(A) R: 57,8 dB(A)	binaural

7 Measurements and Requirements for Basic Parameters

NOTE 1: In general the test methods as described in the present document apply. If alternative methods exist they may be used if they have been proven to give the same result as the method described in the standard. This will be indicated in the test report.

NOTE 2: Due to time variant nature of IP connection, delay variation may impair the measurement. In such case, the measurement has to be repeated until a valid measurement can be achieved.

7.1 Coding independent parameters

7.1.1 Send Frequency Response

7.1.1.1 Requirement

The Send sensitivity/frequency response shall be within the limits given in table 3.

Table 3

Frequency	Upper limit	Lower limit
100 Hz	0 dB	
315 Hz	0 dB	-14 dB
400 Hz	0 dB	-13 dB
500 Hz	0 dB	-12 dB
630 Hz	0 dB	-11 dB
800 Hz	0 dB	-10 dB
1 000 Hz	0 dB	-8 dB
1 300 Hz	2 dB	-8 dB
1 600 Hz	3 dB	-8 dB
2 000 Hz	4 dB	-8 dB
3 100 Hz	4 dB	-8 dB
4 000 Hz	0 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Figure 13: Send frequency response mask for HFT

7.1.1.2 Measurement method

The terminal will be positioned as described in clause 6.1.

An artificial voice according to ITU-T Recommendation P.50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] can be used for test. The type of test signal used shall be stated in the test report. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The signal level is adjusted according to clause 6.2.1.

The spectrum at the MRP and the actual level at the MRP (measured in third octaves) is used as reference to determine the Send sensitivity SmJ .

Measurements shall be made at one twelfth-octave intervals as given by the R.40 series of preferred numbers in ISO 3 [23] for frequencies from 100 Hz to 4 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBV/Pa.

7.1.2 Send Loudness Rating

7.1.2.1 Requirement

The value of SLR shall be $+13 \text{ dB} \pm 3 \text{ dB}$.

This value is derived from ITU-T Recommendation P.310 [16]. According to ITU-T Recommendation P.340 [17] the SLR of a hands-free telephone should be about 5 dB higher than the SLR of the corresponding handset telephone.

This value will be identical for all type of terminal (desktop, handheld, etc.) difference in efficiency will be given by conditions for measurement (see clause 6.1).

7.1.2.2 Measurement method

The terminal will be positioned as described in clause 6.1.

An artificial voice according to ITU-T Recommendation P.50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] can be used to test. The type of test signal used shall be stated in the test report. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The test signal level shall be $-4,7 \text{ dBPa}$, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

Calibration is realized as explained in clause 6.2.1.

SLR shall be calculated according ITU-T Recommendation P.79 [15].

7.1.3 Send Distortion

7.1.3.1 Requirement

The terminal will be positioned as described in clause 6.1.

The ratio of signal to harmonic distortion shall be above the following mask.

Table 3a

Frequency	Ratio
315 Hz	26 dB
400 Hz	30 dB
1 kHz	30 dB
NOTE: Limits at intermediate frequencies lie on a straight line drawn between the given values on a linear (dB ratio) - logarithmic (frequency) scale.	

7.1.3.2 Measurement method

The terminal will be positioned as described in clause 6.1.

The signal used is an activation signal followed by a sine wave signal with a frequency at 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz and 1 000 Hz, the duration of the sine-wave shall be of less than 1 s. The sinusoidal signal level shall be calibrated to $-4,7 \text{ dBPa}$ at the MRP.

The signal to harmonic distortion ratio is measured selectively up to 3,15 kHz.

An artificial voice according to ITU-T Recommendation P.50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] can be used for activation. Level of this activation signal will be $-4,7 \text{ dBPa}$ at the MRP.

NOTE: Depending on the type of codec the test signal used may need to be adapted.

7.1.4 Out-of-band Signals in Send direction

7.1.4.1 Requirement

With any signal above 4,6 kHz and up to 8 kHz applied at the MRP at a level of -4,7 dBPa, the level of any image frequency shall be below the level obtained for the reference signal by at least the amount (in dB) specified in table 4.

Table 4: Out-of-band signal limit, Send

Frequency	Limit
4,6 kHz	30 dB
8 kHz	40 dB
NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.	

7.1.4.2 Measurement method

The terminal will be positioned as described in clause 6.1.

For a correct activation of the system, an artificial voice according to ITU-T Recommendation P.50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] shall be used for activation. Level of this activation signal shall be -4,7 dBPa at the MRP.

For the test, an out-of-band signal shall be provided as a frequency band signal centred on 4,65 kHz, 5 kHz, 6 kHz, 6,5 kHz, 7 kHz and 7,5 kHz respectively. The level of any image frequencies at the digital interface shall be measured.

The levels of these signals shall be -4,7 dBPa at the MRP.

The complete test signal is constituted by t1 ms of in-band signal (reference signal), t2 ms of out-of-band signal and another time t1 ms of in-band signal (reference signal).

The observation of the output signal on the first and second in-band signals permits control if the set is correctly activated during the out-of-band measurement. This measurement shall be performed during t2 period:

- a value of 250 ms is suggested for t1;
- t2 depends on the integration time of the analyser, typically less than 150 ms.

7.1.5 Send Noise

7.1.5.1 Requirement

The limit for the Send noise is the following:

- send noise level maximum -64 dBm0p.

No peaks in the frequency domain higher than 10 dB above the average noise spectrum shall occur.

Requirement as for other tests is identical for all types of terminals.

NOTE: Softphones with cooling devices (fans) can produce a rather high level of noise, furthermore largely dependent of activity of system.

7.1.5.2 Measurement method

The terminal will be positioned as described in clause 6.1.

For a correct activation of the system, an artificial voice according to ITU-T Recommendation P.50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] shall be used for activation. Level of this activation signal shall be -4,7 dBPa at the MRP.

The psophometric noise level at the output of the test setup is measured. The psophometric filter is described in ITU-T Recommendation O.41 [11].

7.1.6 Receive Frequency Response

7.1.6.1 Requirement

The following masks are required for handsfree and loudspeaking terminals.

Desktop operated loudspeaker

Table 5: Receive frequency response mask-desktop

Frequency	Upper limit	Lower limit
100 Hz	6 dB	
315 Hz	6 dB	-9 dB
400 Hz	6 dB	-6 dB
3 100 Hz	6 dB	-6 dB
4 000 Hz	6 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

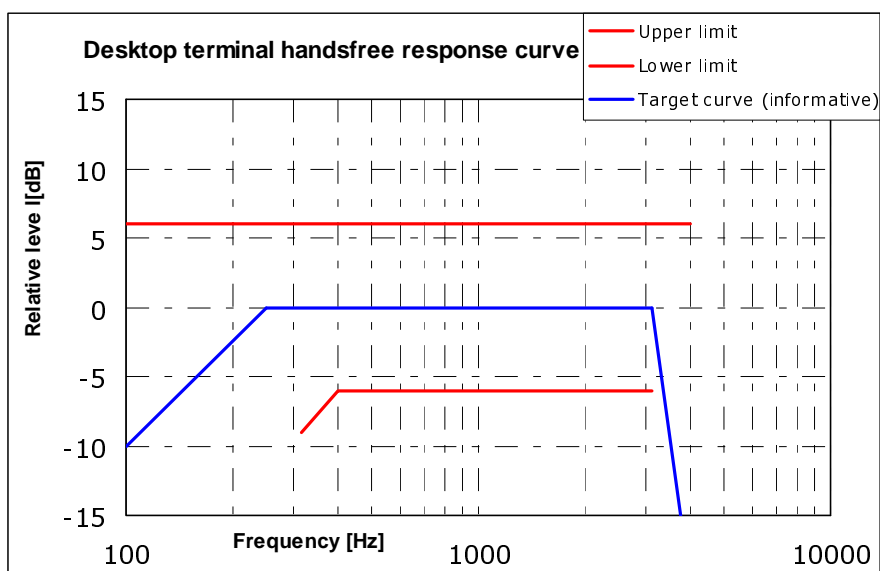

Figure 14: Receive frequency response mask for Desktop hands free terminals

Handheld terminal

Table 6: Receive frequency response mask-handheld

Frequency	Upper limit	Lower limit
100 Hz	6 dB	
500 Hz	6 dB	-9 dB
630 Hz	6 dB	-6 dB
3 100 Hz	6 dB	-6 dB
4 000 Hz	6 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Figure 15: Receive frequency response mask for Hand-held HFTs

Softphone (computer-based terminals)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Group audio terminal

Same requirement as desktop terminals.

7.1.6.2 Measurement method

Test setup is described in clause 6.1.

Measurement is operated at nominal value of volume control.

Receive frequency response is the ratio of the measured sound pressure and the input level. (dB relative Pa/V).

$$S_{\text{Jeff}} = 20 \log (pe_{\text{ff}}/v_{\text{RCV}}) \text{ dB rel 1 Pa/V} \quad (1)$$

Where:

- S_{Jeff} Receive Sensitivity; Junction to HATS Ear with free field correction.
- pe_{ff} DRP Sound pressure measured by ear simulator Measurement data are converted from the Drum Reference Point to free field.
- v_{RCV} Equivalent RMS input voltage.

The test signal to be used for the measurements shall be the artificial voice according to ITU-T Recommendation P.50 [12]. The test signal level shall be -20 dBm0, measured according to ITU-T Recommendation P.56 [13] at the digital reference point or the equivalent analogue point.

The HATS is free field equalized as described in ITU-T Recommendation P.581 [21]. The equalized output signal is power-averaged on the total time of analysis. The 1/12 octave band data are considered as the input signal to be used for calculations or measurements.

Measurements shall be made at one twelfth-octave intervals as given by the R.40 series of preferred numbers in ISO 3 [23] for frequencies from 100 Hz to 4 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBPa/V.

7.1.7 Receive Loudness Rating

7.1.7.1 Requirement

Desktop operated loudspeaker

Nominal value of RLR will be 5 ± 3 dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range must be less than (louder) or equal to -2 dB: $RLR_{max} \leq -2$ dB.

Range of volume control must be equal or exceed 15 dB.

Handheld terminal

Nominal value of RLR will be 9 ± 3 dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range must be less than (louder) or equal to 2 dB: $RLR_{max} \leq 2$ dB.

Range of volume control must be equal or exceed 15 dB.

Softphone (computer-based terminal)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Group audio terminal

Nominal value of RLR will be 5 ± 3 dB. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range must be less than (louder) or equal to -6 dB: $RLR_{max} \leq -6$ dB.

Range of volume control must be equal or exceed 19 dB.

7.1.7.2 Measurement method

Test setup is described in clause 6.1.

The RLR shall be calculated according to ITU-T Recommendation P.79 [15].

The receive sensitivity shall be calculated from each band of the 14 frequencies given in table 1 of ITU-T Recommendation P.79 [15], bands 4 to 17. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dB Pa/V and the RLR(cal) shall be calculated according to the formula 5-1 of ITU-T Recommendation P.79 [15], using the receive weighting factors from table 1 and according to clause 6, of ITU-T Recommendation P.79 [15]; The RLR shall then be computed as RLR(cal) minus 14 dB according to ITU-T Recommendation P.340 [17], and without the LE factor.

7.1.8 Receive Distortion

7.1.8.1 Requirement

Desktop operated loudspeaker

The ratio of signal to harmonic distortion shall be above the following mask.

Table 7

Frequency	Signal to distortion ratio limit, receive for desktop terminal at nominal volume	Signal to distortion ratio limit, receive for handheld terminal at nominal volume	Signal to distortion ratio limit, receive for all terminals at maximum volume
315 Hz	26 dB		
400 Hz	30 dB		
500 Hz	30 dB	20 dB	
800 Hz	30 dB	30 dB	20 dB
1 kHz	30 dB	30 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

Handheld terminal

The terminal will be positioned as described in clause 6.1.

The ratio of signal to harmonic distortion is given in table 7.

Softphone (computer-based terminal)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Group audio terminal

Same requirement as for desktop terminal.

7.1.8.2 Measurement method

Test setup is described in clause 6.1.

The signal used is an activation signal followed by a series sine wave signal with a frequency at 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz and 1 000 Hz, The duration of the sine-wave shall be of less than 1 s. The sinusoidal signal level shall be calibrated to -16 dBm0.

An artificial voice according to ITU-T Recommendation P. 50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] can be used for activation. Level of this activation signal will be -16 dBm0.

The signal to harmonic distortion ratio is measured selectively up to 3,15 kHz.

NOTE: Depending on the type of codec the test signal used may need to be adapted.

7.1.9 Out-of-band Signals in Receive Direction

7.1.9.1 Requirement

Any spurious out-of-band image signals in the frequency range from 4,6 kHz to 8 kHz measured selectively shall be lower than the in-band level measured with a reference signal. The minimum level difference between the reference signal level and the out-of-band image signal level shall be as given in table 8.

Table 8: Out-of-band signal limit, receive

Frequency	Signal limit
4,6 kHz	35 dB
8 kHz	45 dB

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

7.1.9.2 Measurement Method

Test setup is described in clause 6.1.

Measurement is operated at nominal value of volume control.

The signal used is an activation signal followed by a sine wave signal. For input signals at the frequencies 500 Hz, 1 000 Hz, 2 000 Hz and 3 150 Hz applied at the level of -16 dBm0, the level of spurious out-of-band image signals at frequencies up to 8 kHz is measured selectively at measurement point.

An artificial voice according to ITU-Recommendation P 50 [12] or a speech like test signal as described in ITU-T Recommendation P.50 [12] can be used for activation. Level of this activation signal will be -16 dBm0.

7.1.10 Receive Noise

7.1.10.1 Requirement

A-weighted

The noise level shall not exceed -54 dBPa(A) at **nominal setting of the volume control**.

Octave band spectrum

The level in any 1/3-octave band, between 100 Hz and 10 kHz shall not exceed a value of -64 dBPa.

NOTE 1: No peaks in the frequency domain higher than 10 dB above the average noise spectrum should occur.

NOTE 2: For softphone fan noise should be avoided in order to fulfil this condition.

7.1.10.2 Measurement method

Test setup is described in clause 6.1.

A signal is applied to input of test system in order to ensure correct activation of receive state. An artificial voice according to ITU-Recommendation P 50 [12] or a speech like test signal as described in ITU-T Recommendation P.501 [19] can be used for activation. Level of this activation signal will be -16 dBm0.

The noise shall be measured just after interrupting the activation signal.

7.1.11 Terminal Coupling Loss

7.1.11.1 Requirement

In order to meet the ITU-T Recommendation G.131 [6] talker echo objective requirements, the recommended weighted terminal coupling loss during single talk (TCLw) should be greater than 55 dB when measured under free field conditions at nominal setting of volume control.

A TCLw greater than 46 dB is considered as acceptable.

TCLwst shall be not less than 40 dB for any setting of the volume control.

7.1.11.2 Measurement method

The setup for terminal is described in clause 6.1.

For hands-free measurement, the HATS is positioned but not used.

For loudspeaking measurement, the handset is positioned on HATS (right ear).

Before the actual test a training sequence consisting of 10 s male artificial voice followed by 10 s femal artificial voice according to ITU-T Recommendation P.50 [12] is applied. The training sequence level shall be -16 dBm0 in order not to overload the codec.

The test signal following immediately the training sequence is a PN-sequence complying with ITU-T Recommendation P.501 [19] with a length of 4 096 points (for the 48 kHz sampling rate) and a crest factor of 6 dB. The length of the complete test signal composed of at least four sequences of CSS shall be at least one second (1,0 s). The test signal level is -3 dBm0 (from 50 Hz to 4 kHz). The low-crest factor is achieved by random-alternation of the phase between -180° and 180°.

The TCLw is calculated according to ITU-T Recommendation G.122 [5], clause B.4 (trapezoidal rule). For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band. For the measurement a time window (e.g. 200 ms) has to be applied adapted to the duration of the actual pn-sequence of the test signal choosing the pn-sequence of the third CS-Signal.

7.1.12 Stability Loss

7.1.12.1 Requirement

For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band. It must exceed 6 dB for all frequencies and for all settings of volume control.

7.1.12.2 Measurement method

For handsfree mode the test set-up is identical as for TCLw.

For loudspeaking mode handset is placed at 50 cm beside terminal with transducers facing the table as in figure 16.

Figure 16: Stability loss position for loudspeaking function

Before the actual test a training sequence consisting of 10 s male artificial voice followed by 10 s female artificial voice according to ITU-T Recommendation P.50 [12] is applied. The training sequence level shall be -16 dBm0 in order not to overload the codec.

The test signal is a PN sequence complying with ITU-T Recommendation P.501 [19] with a length of 4 096 points (for the 48 kHz sampling rate) and a crest factor of 6 dB. The duration of the test signal is 250 ms. With an input signal of -3 dBm0, the attenuation from digital input to digital output shall be measured for frequencies from 200 Hz to 4 kHz.

7.2 Codec Specific Requirements

7.2.1 Send Delay

For a VoIP terminal, send delay is defined as the one-way delay from the acoustical input (mouthpiece) of this VoIP terminal to its interface to the packet based network. The total send delay is the upper bound on the mean delay and takes into account the delay contributions of all of the elements shown in figure 2 of ITU-T Recommendation G.1020 [10] and in figure A.1 of ITU-T Recommendation G.1020 [10], respectively.

The Send delay $T(s)$ is defined as follows:

$$T(s) = T(ps) + T(la) + T(aif) + T(asp) \quad (\text{formula 1})$$

Where:

- $T(ps)$ = packet size = $N * T(fs)$.
- N = number of frames per packet.
- $T(fs)$ = frame size of encoder.
- $T(la)$ = look-ahead of encoder.
- $T(aif)$ = air interface framing.
- $T(asp)$ = allowance for signal processing.

The additional delay required for IP packet assembly and presentation to the underlying link layer will depend on the link layer. When the link layer is a LAN (e.g. Ethernet), this additional time will usually be quite small. For the purposes of the present document it is assumed that in the test setup this delay can be neglected.

NOTE: The size of $T(aif)$ is for further study.

7.2.1.1 Requirement

The allowance for signal processing shall be $T(asp) < 40$ ms (including processing time for handsfree).

NOTE: With the knowledge of the codec specific values for $T(fs)$ and $T(la)$ the requirements for send delay for any type of coder and any frame size $T(fs)$ can easily be calculated by formula 1. Table 9 provides requirements calculated accordingly for frequently used codecs and packet sizes.

Table 9

Codec	N	T(fs) in ms	T(ps) in ms	T(la) in ms	T(aif) in ms	T(asp) in ms	T(s) Requirement in ms
ITU-T Recommendation G.711 [7]	80	0,125	10	0	0	40	< 50
ITU-T Recommendation G.711 [7]	160	0,125	20	0	0	40	< 60
ITU-T Recommendations G.729, G.729 A and G.729 B [9]	1	10	10	5	0	40	< 55
ITU-T Recommendations G.729, G.729 A and G.729 B [9]	2	10	20	5	0	40	< 65
ITU-T Recommendation G.723.1 [8] (5,3 kbit/s and 6,3 kbit/s)	1	30	30	7,5	0	40	< 77,5

Further information about the different sources of delay for different codecs can be found in annex A.

7.2.1.2 Measurement Method

Test setup is described in clause 6.1.

The test signal to be used for the measurements shall be a Composite Source Signal (CSS) as described in ITU-T Recommendation P.501 [19]. The test signal consists of the voiced part as described in ITU-T Recommendation P.501 [19] followed by a pseudo random noise sequence with a periodicity of minimum 500 ms. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The test signal level shall be -4,7 dBPa, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

NOTE 1: If the expected delay is higher than 500 ms a pseudo random sequence with a higher periodicity should be used.

The delay is calculated using the cross correlation function between the signal at the electrical test point and the signal at the MRP. The cross correlation analysis has to be chosen in such a way that the maximum delay of 500 ms can be analysed. The measurement is corrected by the delay introduced by the test equipment.

The delay is expressed in ms, determined from the maximum of the cross correlation function.

NOTE 2: Delay may be time variant. Therefore constant monitoring of the actual delay may be required when evaluating the range of delay which can be observed in a given connection. The test setup should take into account either real network conditions or the tools needed to simulate typical causes for time variant delay (e.g. packet loss) during the measurement period. Other methods like running cross correlation or delay estimation procedures e.g. used in PESQ (ITU-T Recommendation P.862 [22]) may be used.

7.2.2 Receive delay

For a VoIP terminal, receive delay is defined as the one-way delay from the interface to the packet based network of this VoIP terminal to its acoustical output (ears of HATS) The total receive delay is the upper bound on the mean delay and takes into account the delay contributions of all of the elements shown in figure 3 of ITU-T Recommendation G.1020 [10] and in figure A.2 of ITU-T Recommendation G.1020 [10], respectively.

The receive delay $T(r)$ is defined as follows:

$$T(r) = T(fs) + T(aif) + T(jb) + T(plc) + T(asp) \quad (\text{formula 2})$$

Where:

- $T(fs)$ = frame size of encoder.
- $T(aif)$ = air interface framing.
- $T(jb)$ = jitter buffer size.
- $T(plc)$ = PLC buffer size.
- $T(asp)$ = allowance for signal processing.

The additional delay required for IP packet dis-assembly and presentation from the underlying link layer will depend on the link layer. When the link layer is a LAN (e.g. Ethernet), this additional time will usually be quite small. For the purposes of the present document it is assumed that in the test setup this delay can be neglected.

NOTE: The size of $T(aif)$ is for further study.

7.2.2.1 Requirement

The allowance for signal processing shall be $T(asp) < 10$ ms.

The additional delay introduced by the jitter buffer shall be $T(jb) \leq 10$ ms.

For Coders without integrated PLC the additional PLC buffer size shall be $T(plc) < 10$ ms.

For Coders with integrated PLC the additional PLC buffer size shall be $T(plc) = 0$ ms.

NOTE 1: With the knowledge of the codec specific values for $T(fs)$ and $T(la)$ the requirements for receive delay for any type of coder and any frame size $T(fs)$ can easily be calculated by formula 2. Table 10 provides requirements calculated accordingly for some frequently used codecs and packet sizes as an example.

Table 10

Codec	N	T(fs) in ms	T(aif) in ms	T(jb) in ms	T(plc) in ms	T(asp) in ms	T(r) in ms	T(r) Requirement in ms
ITU-T Recommendation G.711 [7]	80	0,125	0	10	10	10	< 30,125	< 31
ITU-T Recommendation G.711 [7]	160	0,125	0	10	10	10	< 30,125	< 31
ITU-T Recommendations G.729, G.729 A and G.729 B [9]	1	10	0	10	0	10	< 30	< 30
ITU-T Recommendations G.729, G.729 A and G.729 B [9]	2	10	0	10	0	10	< 30	< 30
ITU-T Recommendation G.723.1 [8] (5.3 kbit/s and 6.3 kbit/s)	1	30	0	10	0	10	< 50	< 50
NOTE 1: $T(ps)$ = packet size = N * $T(fs)$.								
NOTE 2: N = number of frames per packet.								

NOTE 2: These requirements are based on the lowest possible delay values which can be expected under ideal network conditions. Caution should be exercised to ensure that the terminal is operated under optimum conditions in order to avoid adverse effects, e.g. network conditions, settings and memory effects of the terminal jitter buffer.

7.2.2.2 Measurement Method

Test setup is described in clause 6.1.

The test signal to be used for the measurements shall be a Composite Source Signal (CSS) as described in ITU-T Recommendation P.501 [19] followed by a pseudo random noise sequence with a periodicity of minimum 500 ms. The test signal level shall be -16 dBm0, measured at the electrical test point. The test signal level is averaged over the complete test signal sequence.

NOTE 1: If the expected delay is higher than 500 ms a pseudo random sequence with a higher periodicity should be used.

The delay is calculated using the cross correlation function between the signal at the electrical test point and the signal at the DRP. The cross correlation analysis has to be chosen in such a way that the maximum delay of 500 ms can be analysed. The measurement is corrected by the delay introduced by the test equipment.

The delay is expressed in ms, determined from the maximum of the cross correlation function.

NOTE 2: Delay may be time variant. Therefore constant monitoring of the actual delay may be required when evaluating the range of delay which can be observed in a given connection. The test setup should take into account either real network conditions or the tools needed to simulate typical causes for time variant delay (e.g. packet loss) during the measurement period. Other methods like running cross correlation or delay estimation procedures e.g. used in PESQ (ITU-T Recommendation P.862 [22]) may be used.

8 Measurements and Requirements for Parameters with respect to Speech Processing Devices

8.1 Objective Listening Speech Quality MOS-LQO in Send direction

For further study.

8.2 Objective Listening Quality MOS-LQO in Receive direction

For further study.

8.3 Minimum activation level and sensitivity in Receive direction

For further study.

8.4 Automatic Level Control in Receive

For further study.

8.5 Double Talk Performance

During double talk the speech is mainly determined by 2 parameters: impairment caused by echo during double talk and level variation between single and double talk (attenuation range).

In order to guarantee sufficient quality under double talk conditions the Talker Echo Loudness Rating should be high and the attenuation inserted should be as low as possible. Terminals which do not allow double talk in any case should provide a good echo attenuation which is realized by a high attenuation range in this case.

The most important parameters determining the speech quality during double talk are (see ITU-T Recommendations P.340 [17] and P.502 [20]):

- Attenuation range in Send direction during double talk $A_{H,S,dt}$.
- Attenuation range in receive direction during double talk $A_{H,R,dt}$.
- Echo attenuation during double talk.

8.5.1 Attenuation Range in Send Direction during Double Talk $A_{H,S,dt}$

8.5.1.1 Requirement

Based on the level variation in Send direction during double talk $A_{H,S,dt}$ the behaviour of the terminal can be classified according to table 11.

Table 11

Category (according to ITU-T Recommendation P.340 [17])	1	2a	2b	2c	3
	<i>Full Duplex Capability</i>	<i>Partial Duplex Capability</i>			<i>No Duplex Capability</i>
$A_{H,S,dt}$ [dB]	≤ 3	≤ 6	≤ 9	≤ 12	> 12

In general this table provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.

8.5.1.2 Measurement Method

Test setup is described in clause 6.1.

The test signal to determine the attenuation range during double talk is shown in figure 17. A sequence of uncorrelated CS signals is used which is inserted in parallel in Send and receive direction.

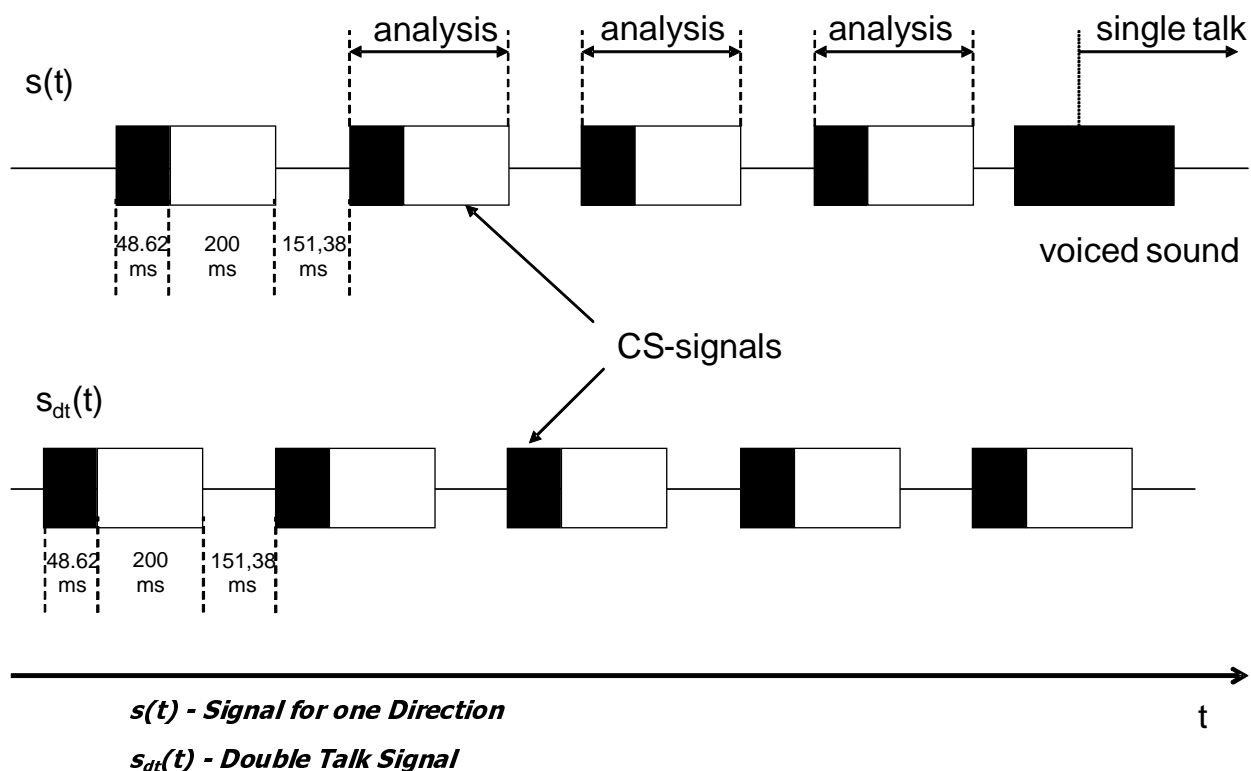

Figure 17: Double Talk Test Sequence with overlapping CS signals in Send and receive direction

Figure 17 indicates that the sequences overlap partially. The beginning of the CS sequence (voiced sound, black) is overlapped by the end of the pn-sequence (white) of the opposite direction. During the active signal parts of one signal the analysis can be conducted in Send and receive direction. The analysis times are shown in figure 17 as well. The test signals are synchronized in time at the acoustical interface. The delay of the test arrangement should be constant during the measurement.

NOTE: The length of voiced sound of the double talk signal is achieved by repeating one period of the voiced sound for double talk according to ITU-T Recommendation P.501 [19] 10 times and cutting off the initial 3,3 ms of the period of the first voiced sound.

The settings for the test signals are as follows:

Table 12

	Receive Direction ($s_{dt}(t)$)	Send Direction ($s(t)$)
Pause Length between two Signal Bursts	151,38 ms	151,38 ms
Average Signal Level (Assuming an Original Pause length of 101,38 ms)	-16 dBm0	-4,7 dBPa
Active Signal Parts	-14,7 dBm0	-3 dBPa

When determining the attenuation range in Send direction the signal measured at the electrical reference point is referred to the test signal inserted.

The level is determined as level vs. time from the time domain. The integration time of the level analysis is 5 ms. The attenuation is determined from the level difference measured at the beginning of the double talk always with the beginning of the CS-signal in Send direction until its complete activation (during the pause in the receive channel). The analysis is performed over the complete signal starting with the second CS-signal. The first CS-signal is not used for the analysis.

8.5.2 Attenuation Range in Receive Direction during Double Talk $A_{H,R,dt}$

8.5.2.1 Requirement

Based on the level variation in receive direction during double talk $A_{H,R,dt}$ the behaviour of the terminal can be classified according to table 13.

Table 13

Category (according to ITU-T Recommendation P.340 [17])	1	2a	2b	2c	3
	<i>Full Duplex Capability</i>	<i>Partial Duplex Capability</i>			<i>No Duplex Capability</i>
$A_{H,R,dt}$ [dB]	≤ 3	≤ 5	≤ 8	≤ 10	> 10

In general table 13 provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.

8.5.2.2 Measurement Method

Test setup is described in clause 6.1.

The test signal to determine the attenuation range during double talk is shown in figure 17. A sequence of uncorrelated CS signals is used which is inserted in parallel in Send and receive direction. The test signals are synchronized in time at the acoustical interface. The delay of the test arrangement should be constant during the measurement.

The settings for the test signals are as follows.

Table 14

	Receive Direction (s(t))	Send Direction (sdt(t))
Pause Length between two Signal Bursts	151,38 ms	151,38 ms
Average Signal Level (Assuming an Original pause Length of 101,38 ms)	-16 dBm0	-4,7 dBPa
Active Signal Parts	-14,7 dBm0	-3 dBPa

When determining the attenuation range in receive direction the signal measured at the artificial ear referred to the test signal inserted.

The level is determined as level vs. time from the time domain. The integration time of the level analysis is 5 ms. The attenuation is determined from the level difference measured at the beginning of the double talk always with the beginning of the CS-signal in receive direction until its complete activation (during the pause in the Send channel). The analysis is performed over the complete signal starting with the second CS-signal. The first CS-signal is not used for the analysis.

8.5.3 Detection of Echo Components during Double Talk

8.5.3.1 Requirement

"Echo Loss" (EL) is the echo suppression provided by the terminal measured at the electrical reference point. Under these conditions the requirements given in table 15 are applicable (more information can be found in annex A of the ITU-T Recommendation P.340 [17]).

Table 15

Category (according to ITU-T Recommendation P.340 [17])	1	2a	2b	2c	3
	Full Duplex Capability	Partial Duplex Capability			No Duplex Capability
Echo Loss [dB]	≥ 27	≥ 23	≥ 17	≥ 11	< 11

NOTE: The echo attenuation during double talk is based on the parameter Talker Echo Loudness Rating ($TELR_{dt}$). It is assumed that the terminal at the opposite end of the connection provides nominal Loudness Rating ($SLR + RLR = 10$ dB).

8.5.3.2 Measurement Method

Test setup is described in clause 6.1.

The double talk signal consists of a sequence of orthogonal signals which are realized by voice-like modulated sine waves spectrally shaped similar to speech. The measurement signals used are shown in the figure below. A detailed description can be found in ITU-T Recommendation P.501 [19].

The signals are fed simultaneously in Send and receive direction. The level in Send direction shall be -4,7 dBPa at the MRP (nominal level), the level in receive direction is -16 dBm0 at the electrical reference point (nominal level).

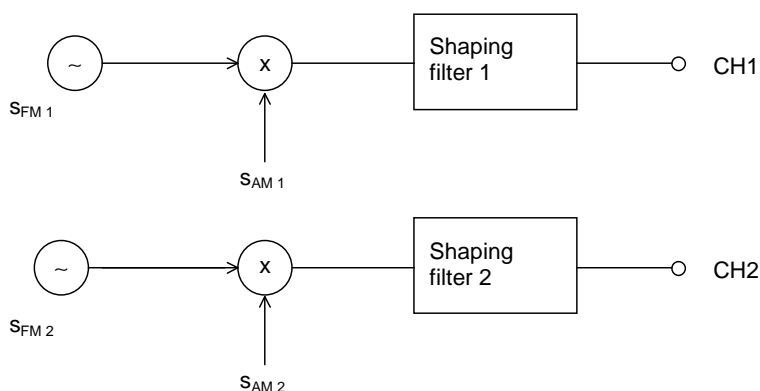

Figure 17a: Measurement signals

$$s_{FM1,2}(t) = \sum A_{FM1,2} \cdot \cos(2\pi t n \cdot F_{01,2}) ; n = 1, 2, \text{ etc.} \quad (2)$$

$$s_{AM1,2}(t) = A_{AM1,2} \cdot \cos(2\pi t F_{AM1,2}); \quad (3)$$

The settings for the signals are as follows.

Table 15a: Settings for the signal

Receive Direction			Send Direction			
f_m [Hz]	$f_{\text{mod(fm)}}$ [Hz]	F_{am} [Hz]		f_m [Hz]	$f_{\text{mod(fm)}}$ [Hz]	F_{am} [Hz]
250	± 5	3		270	± 5	3
500	± 10	3		540	± 10	3
750	± 15	3		810	± 15	3
1 000	± 20	3		1 080	± 20	3
1 250	± 25	3		1 350	± 25	3
1 500	± 30	3		1 620	± 30	3
1 750	± 35	3		1 890	± 35	3
2 000	± 40	3		2 160	± 35	3
2 250	± 40	3		2 400	± 35	3
2 500	± 40	3		2 900	± 35	3
2 750	± 40	3		3 150	± 35	3
3 000	± 40	3		3 400	± 35	3
3 250	± 40	3		3 650	± 35	3
3 500	± 40	3		3 900	± 35	3
3 750	± 40	3				

NOTE: Parameters of the Shaping Filter: Low Pass Filter, 5 dB/oct.

Parameters of the two Test Signals for Double Talk Measurement based on AM-FM modulated sine waves

The test signal is measured at the electrical reference point (Send direction). The measured signal consists of the double talk signal which was fed in by the artificial mouth and the echo signal. The echo signal is filtered by comb filter using mid-frequencies and bandwidth according to the signal components of the signal in receive direction (see ITU-T Recommendation P.501 [19]). The filter will suppress frequency components of the double talk signal.

In each frequency band which is used in receive direction the echo attenuation can be measured separately. The requirement for category 1 is fulfilled if in any frequency band the echo signal is either below the signal noise or below the required limit. If echo components are detectable, the classification is based on table 15a. The echo attenuation is to be achieved for **each individual frequency band** according to the different categories.

8.5.4 Minimum activation level and sensitivity of double talk detection

For further study.

8.5.5 Switching characteristics

NOTE: Additional requirements may be needed in order to further investigate the effect of NLP implementations on the users' perception of speech quality.

8.5.5.1 Activation in Send Direction

The activation in Send direction is mainly determined by the built-up time $T_{r,S,\text{min}}$ and the minimum activation level ($L_{S,\text{min}}$). The minimum activation level is the level required to remove the inserted attenuation in Send direction during idle mode. The built-up time is determined for the test signal burst which is applied with the minimum activation level.

The activation level described in the following is always referred to the test signal level at the Mouth Reference Point (MRP).

8.5.5.1.1 Requirements

The minimum activation level $L_{S,\text{min}}$ shall be ≤ -20 dBPa.

The built-up time $T_{r,S,\text{min}}$ (measured with minimum activation level) should be ≤ 15 ms.

8.5.5.1.2 Measurement Method

Test setup is described in clause 6.1.

The structure of the test signal is shown in figure 18. The test signal consists of CSS components according to ITU-T Recommendation P.501 [19] with increasing level for each CSS burst.

Figure 18: Test Signal to Determine the Minimum Activation Level and the Built-up Time

The settings of the test signal are as follows.

	CSS Duration/ Pause Duration	Level of the first CS Signal (active Signal Part at the MRP)	Level Difference between two Periods of the Test Signal
CSS to Determine Switching Characteristic in Send Direction	~250 ms / ~450 ms	-23 dBPa (see note)	1 dB
NOTE: The level of the active signal part corresponds to an average level of -24,7 dBPa at the MRP for the CSS according to ITU-T Recommendation P.501 [19] assuming a pause of about 100 ms.			

It is assumed that the pause length of about 450 ms is longer than the hang-over time so that the test object is back to idle mode after each CSS burst.

The level of the transmitted signal is measured at the electrical reference point. The measured signal level is referred to the test signal level and displayed vs. time. The levels are calculated from the time domain using an integration time of 5 ms.

The minimum activation level is determined from the CSS burst which indicates the first activation of the test object. The time between the beginning of the CSS burst and the complete activation of the test object is measured.

NOTE: If the measurement using the CS-Signal does not allow to clearly identify the minimum activation level, the measurement may be repeated by using a one syllable word instead of the CS-Signal. The word used should be of similar duration, the average level of the word should be adapted to the CS-signal level of the according CS-burst.

8.5.5.2 Silence Suppression and Comfort Noise Generation

For further study.

8.5.5.3 Performance in Send direction in the presence of background noise

8.5.5.3.1 Requirement

The level of comfort noise, if implemented, shall be within a range of +2 dB and -5 dB compared to the original (transmitted) background noise. The noise level is calculated with psophometric weighting.

NOTE 1: It is advisable that the comfort noise matches the original signal as good as possible (from a perceptual point of view).

NOTE 2: Input for further specification necessary (e.g. on temporal matching).

The spectral difference between comfort noise and original (transmitted) background noise shall be within the mask given through straight lines between the breaking points on a logarithmic (frequency) - linear (dB sensitivity) scale as given in table 16.

Table 16: Requirements for Spectral Adjustment of Comfort Noise (Mask)

Frequency	Upper Limit	Lower Limit
200 Hz	12 dB	-12 dB
800 Hz	12 dB	-12 dB
800 Hz	10 dB	-10 dB
2 000 Hz	10 dB	-10 dB
2 000 Hz	6 dB	-6 dB
4 000 Hz	6 dB	-6 dB
NOTE: All sensitivity values are expressed in dB on an arbitrary scale.		

8.5.5.3.2 Measurement Method

Test setup is described in clause 6.1.

The background noise simulation as described in clause 6.3 is used.

First the background noise transmitted in send is recorded at the POI for a period of at least 20 s.

In a second step a test signal is applied in receive direction consisting of an initial pause of 10 s and a periodical repetition of the Composite Source Signal (CSS) in receive direction (duration 10 s) with nominal level to enable comfort noise injection simultaneously with the background noise. For the measurement the background noise sequence has to be started at the same point as it was started in the previous measurement. Alternatively other speech like test signals (e.g. artificial voice) with the same signal level can be used.

The transmitted signal is recorded in Send direction at the POI.

The power density spectra measured in Send direction without far end speech simulation averaged between 10 s and 20 s is referred to the power density spectrum measured in Send direction determined during the period with far end speech simulation in receive direction averaged between 10 s and 20 s. Level and spectral differences between both power density spectra are analysed and compared to the requirements.

8.5.5.4 Speech Quality in the Presence of Background Noise

8.5.5.4.1 Requirement

Speech Quality for wideband systems can be tested based on EG 202 396-3 [i.4]. The test method is applicable for narrowband (100 Hz to 4 kHz) and wideband (100 Hz to 8 kHz) transmission systems. LQOn is used for narrowband and LQOw is used for wideband systems. The test method described leads to three MOS-LQO quality numbers:

- N-MOS-LQOn: Transmission quality of the background noise.
- S-MOS-LQOn: Transmission quality of the speech.
- G-MOS-LQOn: Overall transmission quality.

For the background noises defined in clause 7.1 the following requirements apply:

- N-MOS-LQOn $\geq 3,0$.
- S-MOS-LQOn $\geq 3,0$.
- G-MOS-LQOn $\geq 3,0$.

NOTE: It is recommended to test the terminal performance with other types of background noises if the terminal is likely to be exposed to other noises than specified in clause 6.1.

8.5.5.4.2 Measurement Method

The background noise simulation as described in clause 7.1 is used. The handset terminal is set-up as described in clause 6.1.

The background noise should be applied for at least 5 s in order to adapt noise reduction algorithms in advance the test.

The near end speech signal consists of 8 sentences of speech (2 male and 2 female talkers, 2 sentences each). Appropriate speech samples can be found in ITU-T Recommendation P.501 [19]. The preferred language is French since the objective method was validated with English language in narrowband. The test signal level is -4,7 dBPa at the MRP.

Three signals are required for the tests:

- 1) The clean speech signal is used as the undisturbed reference (see EG 202 396-3 [i.4]).
- 2) The speech plus undisturbed background noise signal is recorded at the terminal's microphone position using an omni directional measurement microphone with a linear frequency response between 50 Hz and 6 kHz.
- 3) The Send signal is recorded at the electrical reference point.
- 4) N-MOS-LQOn, S-MOS LQOn and G-MOS LQOn are calculated as described in EG 202 396-3 [i.4].

8.5.5.5 Quality of Background Noise Transmission (with Far End Speech)

8.5.5.5.1 Requirements

The test is carried out applying the Composite Source Signal in receive direction. During and after the end of Composite Source Signal bursts (representing the end of far end speech simulation) the signal level in Send direction should not vary more than 10 dB (during transition to transmission of background noise without far end speech). The measurement is conducted for all types of background noise as defined in clause 6.3.

8.5.5.5.2 Measurement Method

Test setup is described in clause 6.1.

The background noises are generated as described in clause 6.3.

First the measurement is conducted without inserting the signal at the far end. At least 10 s of noise are analysed. The background signal level versus time is calculated using a time constant of 35 ms. This is the reference signal.

In a second step the same measurement is conducted but with inserting the CS-signal at the far end. The exactly identical background noise signal is applied. The background noise signal must start at the same point in time which was used for the measurement without far end signal. The background noise should be applied for at least 5 s in order to allow adaptation of the noise reduction algorithms. After at least 5 s a Composite Source Signal according to ITU-T Recommendation P.501 [19] is applied in receive direction with a duration of ≥ 2 CSS periods. The test signal level is -16 dBm0 at the electrical reference point.

The Send signal is recorded at the electrical reference point. The test signal level versus time is calculated using a time constant of 35 ms.

The level variation in Send direction is determined during the time interval when the CS-signal is applied and after it stops. The level difference is determined from the difference of the recorded signal levels vs. time between reference signal and the signal measured with far end signal.

8.5.5.6 Quality of Background Noise Transmission (with Near End Speech)

8.5.5.6.1 Requirement

The test is carried out applying a simulated speech signal in Send direction. During and after the end of the simulated speech signal (Composite Source Signal bursts) the signal level in Send direction should not vary more than 10 dB.

8.5.5.6.2 Measurement Method

Test setup is described in clause 6.1.

The background noises are generated as described in clause 7.1. The background noise should be applied for at least 5 s in order to allow adaptation of the noise reduction algorithms.

The near end speech is simulated using the Composite Source Signal according to ITU-T Recommendation P.501 [19] with a duration of ≥ 2 CSS periods. The test signal level shall be -4,7 dBPa at the MRP.

The Send signal is recorded at the electrical reference point. The test signal level versus time is calculated using a time constant of 35 ms.

First the measurement is conducted without inserting the signal at the near end. The signal level is analysed vs. time. In a second step the same measurement is conducted but with inserting the CS-signal at the near end. The level variation is determined by the difference between the background noise signal level without inserting the CS-signal and the maximum level of the noise signal during and after the CS-bursts in Send direction.

8.5.6 Quality of echo cancellation

8.5.6.1 Temporal echo effects

8.5.6.1.1 Requirement

This test is intended to verify that the system will maintain sufficient echo attenuation during single talk. The measured echo attenuation during single talk should not decrease by more than 6 dB from the maximum measured during the TCLw test.

8.5.6.1.2 Measurement Method

Test setup is described in clause 6.1.

The test signal consists of periodically repeated Composite Source Signal according to ITU-T Recommendation P.501 [19] with an average level of -5 dBm0 as well as an average level of -25 dBm0. The echo signal is analysed during a period of at least 2,8 s which represents 8 periods of the CS signal. The integration time for the level analysis shall be 35 ms, the analysis is referred to the level analysis of the reference signal.

The measurement result is displayed as attenuation vs. time. The exact synchronization between input and output signal has to be guaranteed.

NOTE 1: In addition tests with more speech like signals should be made, e.g. ITU-T Recommendation P.50 [12] to see time variant behaviour of EC. However for such tests the simple broadband attenuation based test principle as described above cannot be applied due to the time varying spectral content of the speech like signals.

NOTE 2: The analysis is conducted only during the active signal part, the pauses between the Composite Source Signals are not analysed. The analysis time is reduced by the integration time of the level analysis (35 ms).

8.5.6.2 Spectral Echo Attenuation

8.5.6.2.1 Requirement

The echo attenuation vs. frequency shall be below the tolerance mask given in table 17.

Table 17: Echo attenuation

Frequency	Limit
100 Hz	-20 dB
200 Hz	-30 dB
300 Hz	-38 dB
800 Hz	-34 dB
1 500 Hz	-33 dB
2 600 Hz	-24 dB
4 000 Hz	-24 dB

NOTE 1: All sensitivity values are expressed in dB on an arbitrary scale.
 NOTE 2: The limit at intermediate frequencies lies on a straight line drawn between the given values on a log (frequency) - linear (dB) scale.

During the measurement it should be ensured that the measured signal is really the echo signal and not the Comfort Noise which possibly may be inserted in Send direction in order to mask the echo signal.

8.5.6.2.2 Measurement Method

Test setup is described in clause 6.1.

Before the actual measurement a training sequence is fed in consisting of 10 seconds CS signal according to ITU-T Recommendation P.501 [19]. The level of the training sequence shall be -16 dBm0.

The test signal consists of a periodically repeated Composite Source Signal. The measurement is carried out under steady-state conditions. The average test signal level is -16 dBm0, averaged over the complete test signal. 4 CS signals including the pauses are used for the measurement which results in a test sequence length of 1,4 s. The power density spectrum of the measured echo signal is referred to the power density spectrum of the original test signal. The analysis is conducted using FFT analysis with 8 k points (48 kHz sampling rate, Hanning window).

The spectral echo attenuation is analysed in the frequency domain in dB.

8.5.6.3 Occurrence of Artifacts

For further study.

8.5.7 Variant Impairments; Network dependant

8.5.7.1 Delay versus Time Send

For further study.

8.5.7.2 Delay versus Time Receive

For further study.

8.5.7.3 Quality of Jitter buffer adjustment

For further study.

Annex A (informative): Processing delays in VoIP terminals

This annex gives some elements about delays generated in VoIP terminals. At first, we consider only wired terminals. These terminals could be schematized as shown in figure A.1.

Figure A.1: Synoptic of the different functions implemented in a VoIP terminal

The implemented functions in the Send part of the terminal are:

- The analogue-digital conversion.
- The encoding.
- The packetization.
- The interfacing with the network.

The implemented functions in the receive part of the terminal are:

- The interfacing with the network.
- The depacketization.
- The buffering.
- The decoding.
- The digital-analogue conversion.

Let us examine each function's contribution to the processing delay characterizing VoIP terminals.

On the Send part of the terminal, the **network interface** operates the transfer of digital data from IP stack to IP network. At the reception, the network interface operates the transfer of digital data from IP network to IP stack. The network interface has a low contribution to the delay. The contribution is estimated at less than 2 ms per transmission way (Send and receive direction).

The **packetization** represents the transfer of the audio frames through the IP stack, from the telephony applicative part of the terminal to the transmission network. The packetization consists in adding specific headers (associated to different protocols) to audio frames. The delay associated to the packetization is considered as no significant and included into encoding time.

Encoding corresponds to the compression of the speech signal. The delay associated to the encoding process depends on the implemented codec and the payload's length (number of audio frames) inserted into each IP packet. On the Send part of the terminal, encoding is the main contribution to the processing delay. The delay can strongly change according to the codec and the payload's length.

Analogue to digital conversion consists in transforming speech signal from analogue to digital format. The processing delay associated to the conversion is considered as no significant.

Digital to analogue conversion consists in transforming speech signal from digital to analogue format. As analogue to digital conversion, the processing delay associated to digital to analogue conversion is considered as not significant.

The **depacketization** represents the transfer of the audio frames through the IP stack, from transmission network to the telephony applicative part of the terminal. The depacketization consists in tacking off the headers associated to protocols to get back audio frames after transmission. The delay associated to the depacketization is considered as no significant and included into the decoding processing time.

The first role of the **jitter buffer** is to ensure synchronization between Send and receive terminals. This synchronization is carried out by buffering the audio frames received from the IP stack before Send them to the decoder. The second role of the jitter buffer is to smooth a possible variation of the transmission time. If synchronization of Send and receive terminals requires a minimum size of buffer, smoothing transmission delay variation requires a buffer size depending on jitter produced by the network. High variations of transmission time involve an important size of the buffer to smooth jitter. Jitter buffers can be implemented either as buffer with static size(s) (several sizes are possible) or as dynamic buffer. In the last case, size management is carried out according to QoS present on the network interface. Jitter buffer is the main contribution to the processing time on the reception part of VoIP terminal.

Decoding corresponds to the rebuilding of speech signal from receive audio frames. The delay associated to decoding depends on the codec implemented. Decoding contributes in a significant way to the processing time on the reception part of VoIP terminal.

Table A.1 presents the processing times of VoIP terminals for different codecs and IP packet payload's lengths.

In this table, x1, x2, x3, x4, y5, x6 and x7 represent the encoding delays according to selected codec. In the same way, y1, y2, y3, y4, y5, y6 and y7 represent the decoding delays according to selected codec.

According to selected codec and payload's length, columns 5 and 6 show overall encoding and decoding delays respectively. Overall encoding time takes into account algorithm, encoding and packetization delays. Overall decoding time takes into account algorithm, decoding and depacketization delays.

Column 7 shows for each codec and payload's length the real time condition. It stands for the maximum duration to encode and decode at the same time. IP terminals have to meet this requirement.

Column 10 shows the minimum delay induced by the jitter buffer. To ensure a correct running of the VoIP terminal, the minimal size of jitter buffer has to correspond to the IP packet payload's length. Furthermore, a double buffering operation induces 10 additional ms in the overall jitter buffer processing.

Column 12 shows the minimum end-to-end delay induced by two terminals connected to a "perfect" network (i.e. with no jitter, no packet loss and with a null transmission delay), with real time condition at the lower limit (i.e. no significant encoding and decoding times).

Column 13 shows the minimum end-to-end delay induced by two terminals connected to a "perfect" network (i.e. with no jitter, no packet loss and with a null transmission delay), with real time condition at the upper limit (i.e. encoding + decoding times very close to the payload size).

Table A.1

Codec	Frame	Lookahead	Payload	Sending processing delay = Algorithm delay + coding and packetization delay	Receiving processing delay = Algorithm delay + coding and packetization delay	Real time condition	Network interface and ADC delay	Network interface and DAC delay	Minimum delay of the jitter buffer	Maximum delay of the jitter buffer	Minimum End to End delay with the lower jitter buffer processing time when real time condition is minimum (x+y=0)	Minimum End to End delay with the lower jitter buffer processing time when real time condition is maximum (x+y=upper limit)	Maximum End to End delay with the higher jitter buffer processing time when real time condition is minimum (x+y=0)	Maximum End to End delay with the higher jitter buffer processing time when real time condition is maximum (x+y=upper limit)
