History 40

Foreword

This draft European Telecommunication Standard (ETS) has been produced by the Technical Committee Special Mobile Group (SMG) Technical Committee of the European Telecommunications Standards Institute (ETSI), and is now submitted for the Unified Approval Procedure phase of the ETSI standards approval procedure.

This ETS specifies the Voice Activity Detector (VAD) to be used in the Discontinuous Transmission (DTX) as described in GSM 06.31 for the digital cellular telecommunications system (Phase 2).

This ETS correspond to GSM technical specification, GSM 06.32 version 4.2.0.

The specification from which this ETS has been derived was originally based on CEPT documentation, hence the presentation of this ETS may not be entirely in accordance with the ETSI/PNE rules.

Reference is made within this ETS to GSM Technical Specifications (GSM-TSs) (NOTE).

NOTE: TC-SMG has produced documents which give the technical specifications for the implementation of the Digital cellular telecommunications system. Historically, these documents have been identified as GSM Technical Specifications (GSM-TS). These TSs may have subsequently become I-ETTs (Phase 1), or ETs (Phase 2), whilst others may become ETSI Technical Reports (ETRs). GSM-TSs are, for editorial reasons, still referred to in GSM ETs.

Proposed transposition dates	
Date of latest announcement of this ETS (doa):	3 months after ETSI publication
Date of latest publication of new National Standard or endorsement of this ETS (dop/e):	6 months after doa
Date of withdrawal of any conflicting National Standard (dow):	6 months after doa

Blank page

0.1 Scope

This European Telecommunication Standard (ETS) specifies the Voice Activity Detector (VAD) to be used in the Discontinuous Transmission (DTX) as described in GSM 06.31. It also specifies the test methods to be used to verify that a VAD complies with the technical specification.

The requirements are mandatory on any VAD to be used either in the GSM Mobile Stations or Base Station Systems.

0.2 Normative references

This ETS incorporates by dated and undated reference, provisions from other publications. These normative references are cited at the appropriate places in the text and the publications are listed hereafter. For dated references, subsequent amendments to or revisions of any of these publications apply to this ETS only when incorporated in it by amendment or revision. For undated references, the latest edition of the publication referred to applies.

0.3 Abbreviations

Abbreviations used in this ETS are listed in GSM 01.04.

1 General

The function of the VAD is to indicate whether each 20ms frame produced by the speech encoder contains speech or not. The output is a binary flag which is used by the TX DTX handler defined in GSM 06.31.

The technical specification is organised as follows:

Section 2 describes the principles of operation of the VAD.

In section 3, the computational details necessary for the fixed point implementation of the VAD algorithm are given. This section uses the same notation as used for computational details in GSM 06.10.

The verification of the VAD is based on the use of digital test sequences. Section 4 defines the input and output signals and the test configuration, whereas the detailed description of the test sequences is contained in Annex 2.

The performance of the VAD algorithm is characterised by the amount of audible speech clipping it introduces and the percentage activity it indicates. These characteristics for the VAD defined in this technical specification have been established by extensive testing under a wide range of operating conditions. The results are summarised in Annex 3.

2 Functional description

The purpose of this section is to give the reader an understanding of the principles of operation of the VAD, whereas the detailed description is given in section 3. In case of discrepancy between the two descriptions, the detailed description of section 3 shall prevail.

In the following subsections of section 2, a Pascal programming type of notation has been used to describe the algorithm.

2.1 Overview and principles of operation

The function of the VAD is to distinguish between noise with speech present and noise without speech present. The biggest difficulty for detecting speech in a mobile environment is the very low speech/noise ratios which are often encountered. The accuracy of the VAD is improved by using filtering to increase the speech/noise ratio before the decision is made.

For a mobile environment, the worst speech/noise ratios are encountered in moving vehicles. It has been found that the noise is relatively stationary for quite long periods in a mobile environment. It is therefore possible to use an adaptive filter with coefficients obtained during noise, to remove much of the vehicle noise.

The VAD is basically an energy detector. The energy of the filtered signal is compared with a threshold; speech is indicated whenever the threshold is exceeded.

The noise encountered in mobile environments may be constantly changing in level. The spectrum of the noise can also change, and varies greatly over different vehicles. Because of these changes the VAD threshold and adaptive filter coefficients must be constantly adapted. To give reliable detection the threshold must be sufficiently above the noise level to avoid noise being identified as speech but not so far above it that low level parts of speech are identified as noise. The threshold and the adaptive filter coefficients are only updated when speech is not present. It is, of course, potentially dangerous for a VAD to update these values on the basis of its own decision. This adaptation therefore only occurs when the signal seems stationary in the frequency domain but does not have the pitch component inherent in voiced speech. A tone detector is also used to prevent adaptation during information tones.

A further mechanism is used to ensure that low level noise (which is often not stationary over long periods) is not detected as speech. Here, an additional fixed threshold is used.

A VAD hangover period is used to eliminate mid-burst clipping of low level speech. Hangover is only added to speech-bursts which exceed a certain duration to avoid extending noise spikes.

2.2 Algorithm description

The block diagram of the VAD algorithm is shown in figure 2-1. The individual blocks are described in the following sections. ACF, N and sof are calculated in the speech encoder.

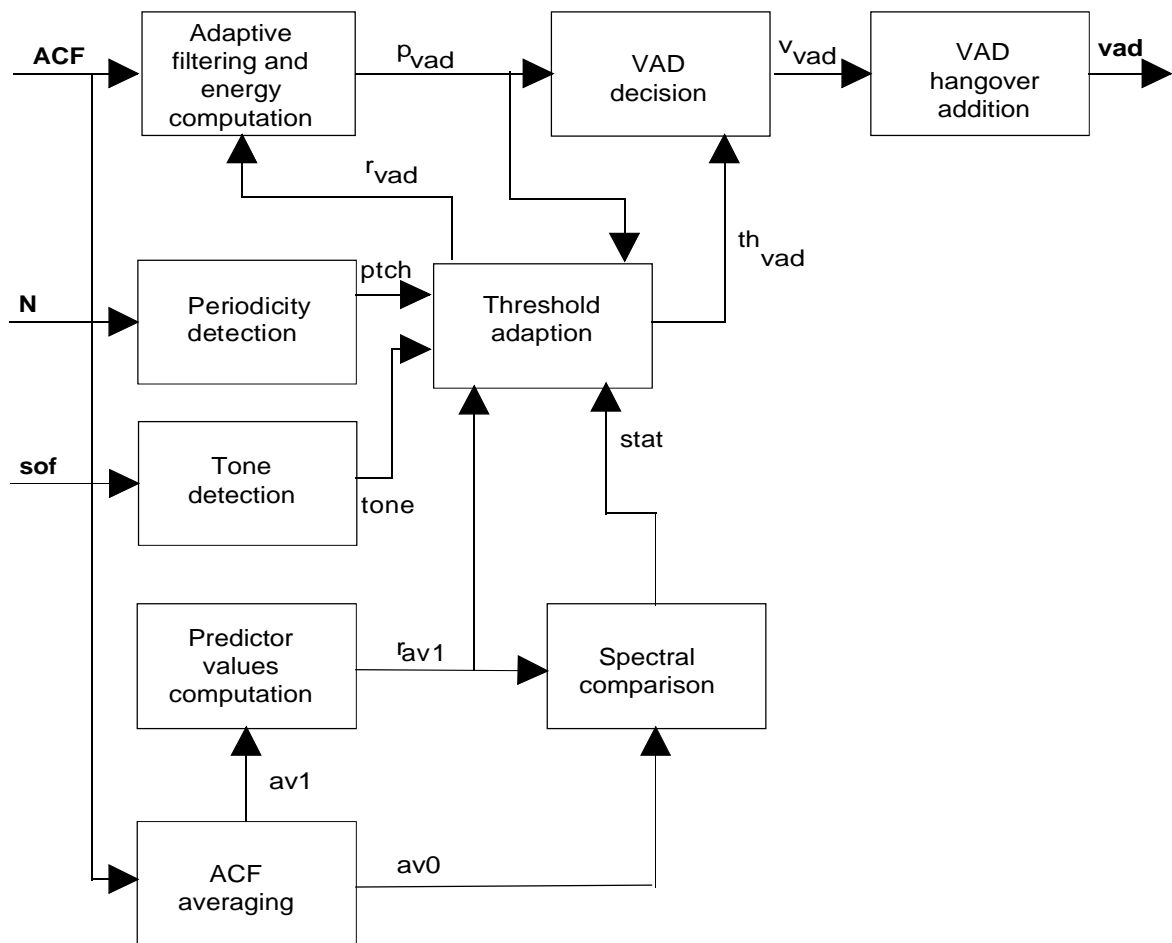

Figure 2-1: Functional block diagram of the VAD

The global variables shown in the block diagram are described as follows:

- ACF are autocorrelation coefficients which are calculated in the speech encoder defined in GSM 06.10 (section 3.1.4, see also Annex 1). The inputs to the speech encoder are 16 bit 2's complement numbers, as described in GSM 06.10, section 4.2.0.
- av0 and av1 are averaged ACF vectors.
- rav1 are autocorrelated predictor values obtained from av1.
- rvad are the autocorrelated predictor values of the adaptive filter.
- N is the long term predictor lag value which is obtained every subsegment in the speech coder defined in GSM 06.10.
- ptch indicates whether the signal has a steady periodic component.
- sof is the offset compensated signal frame obtained in the speech coder defined in GSM 06.10.
- pvad is the energy in the current frame of the input signal after filtering.
- thvad is an adaptive threshold.
- stat indicates spectral stationarity.
- v_vad indicates the VAD decision before hangover is added.
- vad is the final VAD decision with hangover included.

2.2.1 Adaptive filtering and energy computation

Pvad is computed as follows:

$$Pvad := rvad[0] ACF[0] + 2 \sum_{i=1}^8 rvad[i] ACF[i]$$

This corresponds to performing an 8th order block filtering on the input samples to the speech encoder, after zero offset compensation and pre-emphasis. This is explained in Annex 1.

2.2.2 ACF averaging

Spectral characteristics of the input signal have to be obtained using blocks that are larger than one 20ms frame. This is done by averaging the autocorrelation values for several consecutive frames. This averaging is given by the following equations:

$$av0\{n\}[i] := \sum_{j=0}^{frames-1} ACF\{n-j\}[i] \quad ; i = 0..8$$

$$av1\{n\}[i] := av0\{n-frames\}[i] \quad ; i = 0..8$$

Where n represents the current frame, n-1 represents the previous frame etc. The values of constants are given in table 2-1.

Table 2-1. Constants and variables for ACF averaging

Constant	Value	Variable	Initial value
frames	4	previous ACF's av0 & av1	All set to 0

2.2.3 Predictor values computation

The filter predictor values $aav1$ are obtained from the autocorrelation values $av1$ according to the equation:

$$\underline{a} := \underline{R}^{-1} \underline{p}$$

where:

$$\underline{R} := \begin{bmatrix} av1[0], av1[1], av1[2], av1[3], av1[4], av1[5], av1[6], av1[7] \\ av1[1], av1[0], av1[1], av1[2], av1[3], av1[4], av1[5], av1[6] \\ av1[2], av1[1], av1[0], av1[1], av1[2], av1[3], av1[4], av1[5] \\ av1[3], av1[2], av1[1], av1[0], av1[1], av1[2], av1[3], av1[4] \\ av1[4], av1[3], av1[2], av1[1], av1[0], av1[1], av1[2], av1[3] \\ av1[5], av1[4], av1[3], av1[2], av1[1], av1[0], av1[1], av1[2] \\ av1[6], av1[5], av1[4], av1[3], av1[2], av1[1], av1[0], av1[1] \\ av1[7], av1[6], av1[5], av1[4], av1[3], av1[2], av1[1], av1[0] \end{bmatrix}$$

and:

$$\underline{p} := \begin{bmatrix} av1[1] \\ av1[2] \\ av1[3] \\ av1[4] \\ av1[5] \\ av1[6] \\ av1[7] \\ av1[8] \end{bmatrix} \quad \underline{a} := \begin{bmatrix} aav1[1] \\ aav1[2] \\ aav1[3] \\ aav1[4] \\ aav1[5] \\ aav1[6] \\ aav1[7] \\ aav1[8] \end{bmatrix}$$

$$aav1[0] := -1$$

$av1$ is used in preference to $av0$ as $av0$ may contain speech.

The autocorrelated predictor values $rav1$ are then obtained:

$$rav1[i] := \sum_{k=0}^{8-i} aav1[k] aav1[k+i] \quad ; \quad i = 0..8$$

2.2.4 Spectral comparison

The spectra represented by the autocorrelated predictor values $rav1$ and the averaged autocorrelation values $av0$ are compared using the distortion measure dm defined below. This measure is used to produce a boolean value $stat$ every 20ms, as given by these equations:

```

dm := ( rav1[0]av0[0] + 2  $\sum_{i=1}^8$  rav1[i]av0[i] ) / av0[0]

difference := |dm - lastdm|

lastdm := dm

stat := difference < thresh
    
```

The values of constants and initial values are given in table 2-2.

Table 2-2. Constants and variables for spectral comparison

Constant:	Value:	Variable:	Initial value:
thresh	0.05	lastdm	0

2.2.5 Periodicity detection

The frequency spectrum of mobile noise is relatively stationary over quite long periods. The Inverse Filter Autocorrelated Predictor coefficients of the adaptive filter rvad are only updated when this stationarity is detected. Vowel sounds however, also have this stationarity, but can be excluded by detecting the periodicity of these sounds using the long term predictor lag values (Nj) which are obtained every subsegment from the speech codec defined in GSM 06.10. Consecutive lag values are compared. Cases in which one lag value is a factor of the other are catered for, however cases in which both lag values have a common factor, are not. This case is not important for speech input but this method of periodicity detection may fail for some sine waves. The boolean variable ptch is updated every 20ms and is true when periodicity is detected. It is calculated according to the following equation:

```
ptch := oldlagcount + veryoldlagcount >= nthresh
```

The following operations are done after the VAD decision and when the current LTP lag values (N0 .. N3) are available, this reduces the delay of the VAD decision. (N{-1} = N3 of previous segment.)

```

lagcount := 0

for j := 0 to 3 do
begin
    smalllag := maximum(Nj,N{j-1}) mod minimum(Nj,N{j-1})
    if minimum(smalllag,minimum(Nj,N{j-1})-smalllag) < lthresh
        then increment(lagcount)
end

veryoldlagcount := oldlagcount

oldlagcount := lagcount
    
```

The values of constants and initial values are given in table 2-3.

Table 2-3. Constants and variables for periodicity detection

Constant:	Value:	Variable:	Initial value:
lthresh	2	oldlagcount	0
nthresh	4	veryoldlagcount	0
		N3	40

2.2.6 Information tone detection

The tone flag is only evaluated in the downlink VAD. In the uplink VAD, tone detection is not performed and tone = false.

Computation of the tone flag is complex. It is therefore evaluated after the processing of the current speech encoder frame. In this way transmission of the speech or SID frame is not delayed.

Information tones and environmental noise can be classified by inspecting the short term prediction gain, information tones resulting in higher prediction gains than environmental noise. Tones can therefore be detected by comparing the prediction gain to a fixed threshold. By limiting the prediction gain calculation to a fourth order analysis, information signals consisting of one or two tones can be detected whilst minimising the prediction gain for environmental noise.

The prediction gain decision is implemented by comparing the normalised prediction error with a threshold. This measure is used to evaluate the Boolean variable tone every 20 ms. The signal is classified as a tone if the prediction error is smaller than the threshold predth. This is equivalent to a prediction gain threshold of 13.5 dB.

Mobile noise can contain very strong resonances at low frequencies, resulting in a high prediction gain. A further test is therefore made to determine the pole frequency of a second order analysis of the signal frame. The signal is classified as noise if the frequency of the pole is less than 385 Hz. The pole frequency calculation is described in Annex 4.

The algorithm for detecting information tones is as follows:

```

tone := false

den := a[1]*a[1]
num := 4*a[2] - a[1]*a[1]

if ( num <= 0 )
    return

if (( a[1] < 0 ) AND ( num / den < freqth ))
    return

prederr := MULT (1 - RC[i]*RC[i])
           i=1

if (prederr < predth)
    tone := true

return

```

The values of the constants are given in table 2-4. The coefficients a[0..2] are transversal filter coefficients calculated from RC[1..2]. The calculation of the reflection coefficients RC[1..4] is described below.

The offset compensated signal frame $\text{sof}[0..159]$ is multiplied by the Hanning window to give the windowed frame $\text{sofh}[0..159]$:

$$\text{sofh}[i] := \text{sof}[i] * \text{hann}[i]; \quad i = 0..159$$

where

$$\text{hann}[i] := 0.5 * (1 - \cos(2 * \pi * (i/159))); \quad i = 0..159.$$

The autocorrelation $\text{acfh}[0..4]$ of the windowed signal frame is then calculated:

$$\text{acfh}[k] := \sum_{i=k}^{159} \text{sofh}[i] * \text{sofh}[i-k]; \quad k = 0..4.$$

$\text{RC}[1..4]$ are then calculated from $\text{acfh}[0..4]$ using the Schur recursion described in the RPE-LTP codec.

Table 2-4. Constants for information tone detection.

Constant	Value
freqth	0,0973
predth	0,0158

NOTE: Reflection coefficients are available in the RPE-LTP codec. However, they are calculated after pre-emphasis using a rectangular window and do not give good tone detection results.

2.2.7 Threshold adaptation

A check is made every 20ms to determine whether the VAD decision threshold (thvad) should be changed. This adaptation is carried out according to the flowchart shown in figure 2-2. The constants used are given in table 2-5.

Adaptation takes place in two different situations: firstly whenever $\text{ACF}[0]$ is very low and secondly whenever there is a very high probability that speech and information tones are not present.

In the first case, the threshold is adapted if the energy of the input signal is less than pth . The threshold is set to plev without carrying out any further tests because at these very low levels the effect of the signal quantization makes it impossible to obtain reliable results from these tests.

In the second case, the decision threshold (thvad) and the adaptive filter coefficients (rvad) are only updated with the rav1 values when there is a very high probability that speech and information tones are not present. Adaptation occurs if the following conditions are met over a number (adp) of signal frames:

- Stationarity is detected in the frequency domain.
- The signal does not contain a periodic component.
- Information tones are not present.

The step-size by which the threshold is adapted is not constant but a proportion of the current value (determined by constants dec and inc). The adaptation begins by experimentally multiplying the threshold by a factor of $(1-1/\text{dec})$. If the new threshold is now higher than or equal to P_{vad} times fac then the threshold needed to be decreased and it is left at this new lower level. If, on the other hand, the new threshold level is less than P_{vad} times fac then the threshold either needed to be increased or kept constant. In this case it is set to P_{vad} times fac unless this would mean multiplying it by more than a factor of $(1+1/\text{inc})$ (in which case it is multiplied by a factor of $(1+1/\text{inc})$). The threshold is never allowed to be greater than $P_{\text{vad}}+\text{margin}$.

Table 2-5. Constants and variables for threshold adaptation

Constant:	Value:	Variable:	Initial value:
pth	300000	adaptcount	0
plev	800000	thvad	1000000
fac	3.0	rvad[0]	6
adp	8	rvad[1]	-4
inc	16	rvad[2]	1
dec	32	rvad[3] to	
margin	80000000	rvad[8]	All 0

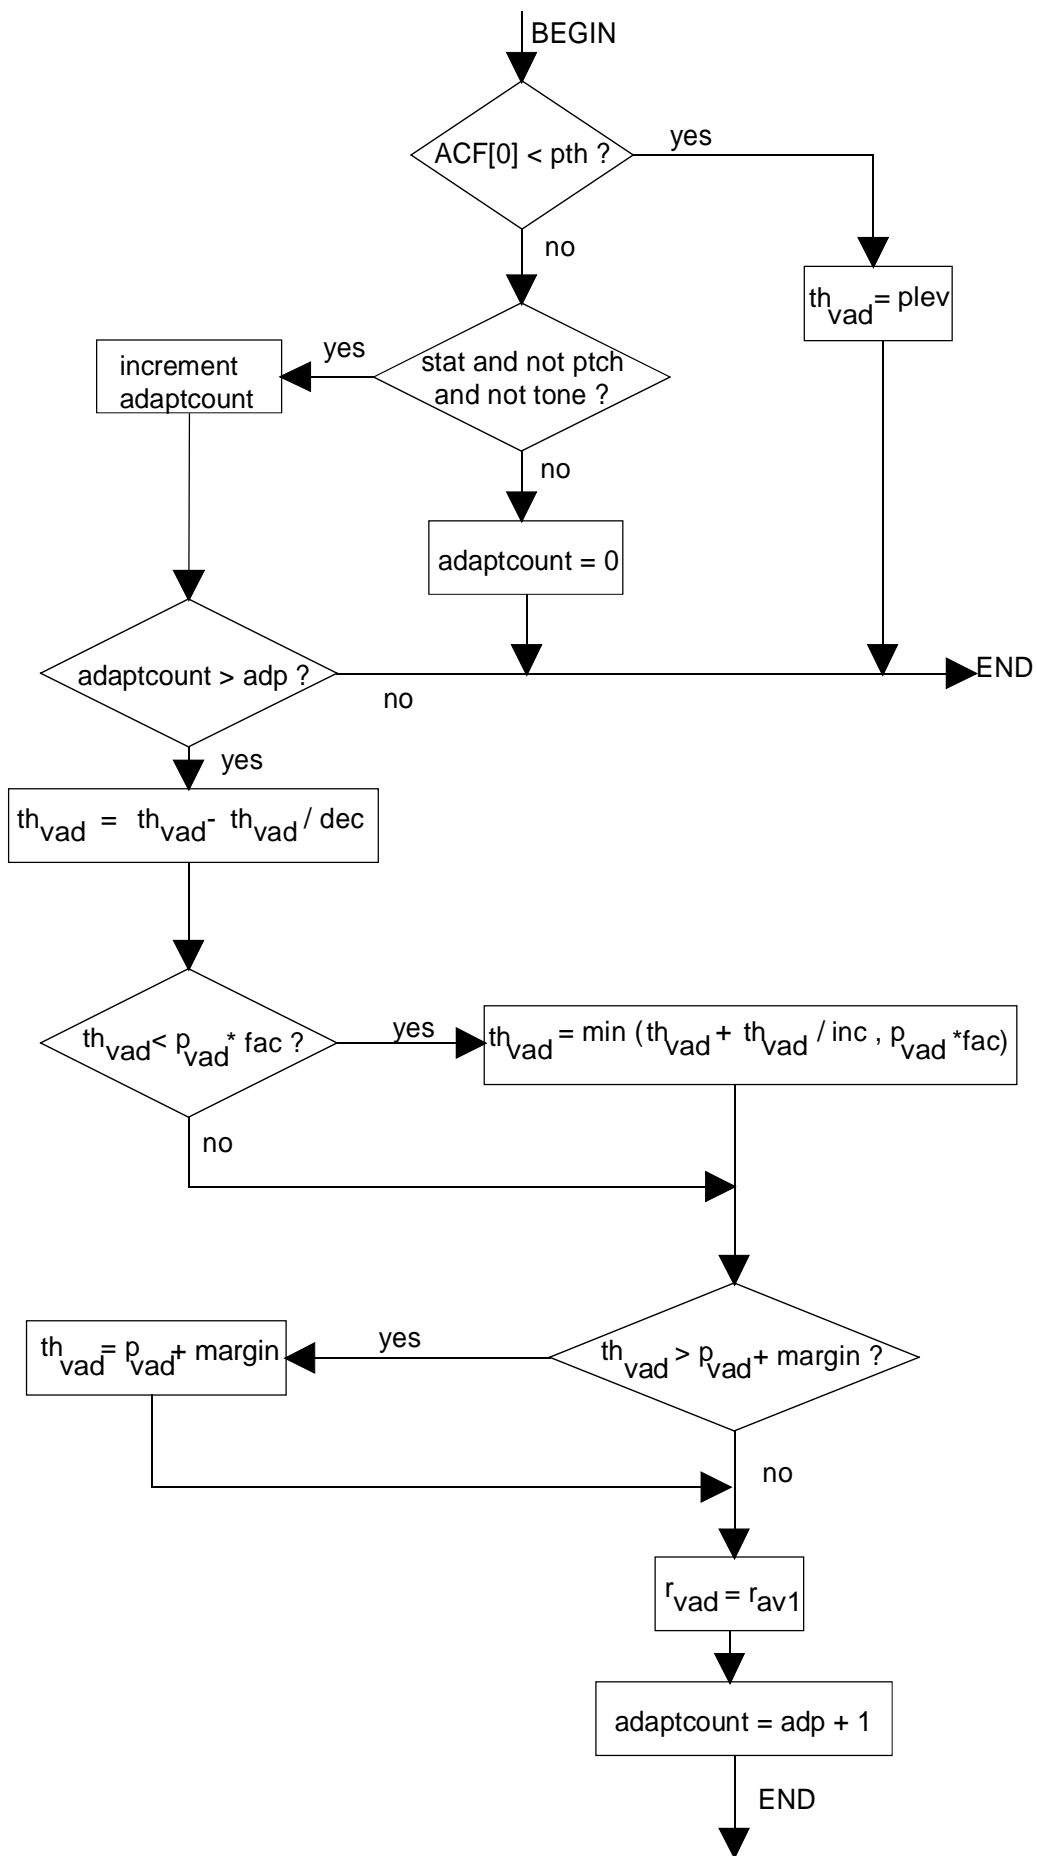

Figure 2-2: Flow diagram for threshold adaption

2.2.8 VAD decision

Prior to hangover the VAD decision condition is:

```
vvad := pvad > thvad
```

2.2.9 VAD hangover addition

VAD hangover is only added to bursts of speech greater than or equal to burstconst blocks. The boolean variable vad indicates the decision of the VAD with hangover included. The values of the constants are given in table 2-6. The hangover algorithm is as follows:

```
if vvad then increment(burstcount) else burstcount := 0

if burstcount >= burstconst then
begin
  hangcount := hangconst;
  burstcount := burstconst
end

vad := vvad or (hangcount >= 0)

if hangcount >= 0 then decrement(hangcount)
```

Table 2-6. Constants and variables for VAD hangover addition

Constant:	Value:	Variable:	Initial value:
burstconst	3	burstcount	0
hangconst	5	hangcount	-1

3 Computational details

In the next paragraphs, the detailed description of the VAD algorithm follows the preceding high level description. This detailed description is divided in ten sections related to the blocks of figure 2-1 (except periodicity updating) in the high level description of the VAD algorithm.

Those sections are:

- 1) Adaptive filtering and energy computation;
- 2) ACF averaging;
- 3) Predictor values computation;
- 4) Spectral comparison;
- 5) Periodicity detection;
- 6) Threshold adaptation;
- 7) VAD decision;
- 8) VAD hangover addition;
- 9) Periodicity updating.
- 10) Information tone detection

The VAD algorithm takes as input the following variables of the RPE-LTP encoder (see the detailed description of the RPE-LTP encoder GSM 06.10):

- L_ACF[0..8], autocorrelation function (GSM 06.10/4.2.4);
- scalauto, scaling factor to compute the L_ACF[0..8] (GSM 06.10/4.2.4);
- Nc, LTP lag (one for each sub-segment, GSM 06.10/4.2.11).
- sof, offset compensated signal frame (GSM 06.10/4.2.2).

So four Nc values are needed for the VAD algorithm.

The VAD computation can start as soon as the L_ACF[0..8] and scalauto variables are known. This means that the VAD computation can take place after part 4.2.4 of GSM 06.10 (Autocorrelation) of the LPC analysis section of the RPE-LTP encoder. This scheme will reduce the delay to yield the VAD information. The periodicity updating (included in section 2.2.5) and information tone detection, are done after the processing of the current speech encoder frame.

All the arithmetic operations and names of the variables follow the RPE-LTP detailed description. To increase the precision within the fixed point implementation, a pseudo-floating point representation of some variables is used. This stands for the following variables (and related constants) of the VAD algorithm:

pvad: Energy of filtered signal;
 thvad: Threshold of the VAD decision;
 acf0: Energy of input signal.

For the representation of these variables, two integers (16 bits) are needed:

- one for the exponent (e_pvad, e_thvad, e_acf0);
- one for the mantissa (m_pvad, m_thvad, m_acf0).

The value e_pvad represents the lowest power of 2 just greater or equal to the actual value of pvad and the m_pvad value represents a integer which is always greater or equal to 16384 (normalized mantissa). It means that the pvad value is equal to:

$$pvad = 2^{(e_pvad)} \times (m_pvad/32768).$$

This scheme guarantees a large dynamic range for the pvad value and always keeps a precision of 16 bits. All the comparisons are easy to make by comparing the exponents of two variables and the VAD algorithm needs only one pseudo-floating point addition. All the computations related to the pseudo-floating point variables require very simple 16 or 32 bits arithmetic operations defined in the detailed description of the RPE-LTP encoder. This pseudo-floating point arithmetic is only used in section 3.1 and 3.6.

Table 3-1 gives a list of all the variables of the VAD algorithm that must be initialized in the reset procedure and kept in memory for processing the subsequent frame of the RPE- LTP encoder. The types (16 or 32 bits) and initial values of all these variables are clearly indicated and their related sub-section is also mentionned. The bit exact implementation uses other temporary variables that are introduced in the detailed description whenever it is needed.

Table 3-1. Initial values for variables to be stored in memory

```

3.1 Adaptive filtering and energy computation

This section computes the `e_pvad` and `m_pvad` variables which represent the `pvad` value. It needs the `L_ACF[0..8]` and `scalauto` variables of the RPE-LTP algorithm and the `rvad[0..8]` and `normrvad` variables produced by section 3.6 of the VAD algorithm. It also computes a floating point representation of `L_ACF[0]` (`e_acf0` and `m_acf0`) used in section 3.6.

Test if L_ACF[0] is equal to 0:

```

IF ( scalauto < 0 ) THEN scalvad = 0;
ELSE scalvad = scalauto; / keep scalvad for use in section 3.2 /

IF ( L_ACF[0] == 0 ) THEN
    e_pvad = -32768;
    m_pvad = 0;
    e_acf0 = -32768;
    m_acf0 = 0;
    EXIT /continue with section 3.2/

```

Re-normalization of the L_acf[0..8]:

```

normacf = norm( L_ACF[0] );

FOR i = 0 to 8:
    sacf[i] = ( L_ACF[i] << normacf ) >> 19;
NEXT i:

```

Computation of e_acf0 and m_acf0:

```

e_acf0 = add( 32, (scalvad << 1) );
e_acf0 = sub( e_acf0, normacf );
m_acf0 = sacf[0] << 3;

```

Computation of e_pvad and m_pvad:

```

e_pvad = add( e_acf0, 14 );
e_pvad = sub( e_pvad, normrvad );

L_temp = 0;

FOR i = 1 to 8:
    L_temp = L_add( L_temp, L_mult( sacf[i], rvad[i] ) );
NEXT i:

L_temp = L_add( L_temp, L_mult( sacf[0], rvad[0] ) >> 1 );

IF ( L_temp <= 0 ) THEN L_temp = 1;

normprod = norm( L_temp );
e_pvad = sub( e_pvad, normprod );
m_pvad = ( L_temp << normprod ) >> 16;

```

3.2 ACF averaging

This section uses the L_ACF[0..8] and the scalvad variables to compute the array L_av0[0..8] and L_av1[0..8] used in section 3.3 and 3.4.

Computation of the scaling factor:

```

scal = sub( 10, (scalvad << 1) );

```

Computation of the arrays L_av0[0..8] and L_av1[0..8]:

```

FOR i = 0 to 8:
  L_temp = L_ACF[i] >> scal;
  L_av0[i] = L_add( L_sacf[i], L_temp );
  L_av0[i] = L_add( L_sacf[i+9], L_av0[i] );
  L_av0[i] = L_add( L_sacf[i+18], L_av0[i] );
  L_sacf[ pt_sacf + i ] = L_temp;
  L_av1[i] = L_sav0[ pt_sav0 + i ];
  L_sav0[ pt_sav0 + i ] = L_av0[i];
NEXT i:

```

Update of the array pointers:

```

IF ( pt_sacf == 18 ) THEN pt_sacf = 0;
ELSE pt_sacf = add( pt_sacf, 9);

```

```

IF ( pt_sav0 == 27 ) THEN pt_sav0 = 0;
ELSE pt_sav0 = add( pt_sav0, 9);

```

3.3 Predictor values computation

This section computes the array rav1[0..8] needed for the spectral comparison and the threshold adaptation. It uses the L_av1[0..8] computed in section 3.2, and is divided in the three following sub-sections:

- Schur recursion to compute reflection coefficients.
- Step up procedure to obtain the aav1[0..8].
- Computation of the rav1[0..8].

3.3.1 Schur recursion to compute reflection coefficients

This sub-section is identical to the one used in the RPE-LTP algorithm. The array vpar[1..8] is computed with the array L_av1[0..8] as an input.

Schur recursion with 16 bits arithmetic:

```

IF( L_av1[0] == 0 ) THEN
  == FOR i = 1 to 8:
  ==   vpar[i] = 0;
  == NEXT i:
  == EXIT; /continue with section 3.3.2/
temp = norm( L_av1[0] );
== FOR k=0 to 8:
  ==   sacf[k] = ( L_av1[k] << temp ) >> 16;
== NEXT k:

```

Initialize array P[...] and K[...] for the recursion:

```

== FOR i=1 to 7:
    K[9-i] = sacf[i];
== NEXT i:

== FOR i=0 to 8:
    P[i] = sacf[i];
== NEXT i:

```

Compute reflection coefficients:

```

== FOR n=1 to 8:
    IF( P[0] < abs( P[1] ) ) THEN
        == FOR i = n to 8:
            vpar[i] = 0;
        == NEXT i:
        EXIT; /continue with
            section 3.3.2/
    vpar[n] = div( abs( P[1] ), P[0] );
    IF ( P[1] > 0 ) THEN vpar[n] = sub( 0, vpar[n] );
    IF ( n == 8 ) THEN EXIT; /continue with section 3.3.2/

    Schur recursion:

    P[0] = add( P[0], mult_r( P[1], vpar[n] ) );
==== FOR m=1 to 8-n:
    P[m] = add( P[m+1], mult_r( K[9-m], vpar[n] ) );
    K[9-m] = add( K[9-m], mult_r( P[m+1], vpar[n] ) );
==== NEXT m:

== NEXT n:

```

3.3.2 Step-up procedure to obtain the aav1[0..8]

Initialization of the step-up recursion:

```

L_coef[0] = 16384 << 15;
L_coef[1] = vpar[1] << 14;

```

Loop on the LPC analysis order:

```

= FOR m = 2 to 8:
== FOR i = 1 to m-1:
== temp = L_coef[m-i] >> 16; / takes the msb /
== L_work[i] = L_add( L_coef[i], L_mult( vpar[m], temp ) );
== NEXT i
=
== FOR i = 1 to m-1:
== L_coef[i] = L_work[i];
== NEXT i
=
= L_coef[m] = vpar[m] << 14;
= NEXT m:

```

Keep the aav1[0..8] on 13 bits for next section:

```

| FOR i = 0 to 8:
|   aav1[i] = L_coef[i] >> 19;
| NEXT i:

```

3.3.3 Computation of the rav1[0..8]

```

|= FOR i= 0 to 8:
|= L_work[i] = 0;
== FOR k = 0 to 8-i:
== L_work[i] = L_add( L_work[i], L_mult( aav1[k], aav1[k+i] ) );
== NEXT k:
= NEXT i:

```

```

IF ( L_work[0] == 0 ) THEN normrav1 =0;
ELSE normrav1 = norm( L_work[0] );

```

```

|= FOR i= 0 to 8:
|= rav1[i] = ( L_work[i] << normrav1 ) >> 16;
|= NEXT i:

```

Keep the normrav1 for use in section 3.4 and 3.6.

3.4 Spectral comparison

This section computes the variable stat needed for the threshold adaptation. It uses the array L_av0[0..8] computed in section 3.2 and the array rav1[0..8] computed in section 3.3.3.

Re-normalize L_av0[0..8]:

```

IF ( L_av0[0] == 0 ) THEN
    FOR i = 0 to 8:
        sav0[i] = 4095;
    NEXT i:
ELSE
    shift = norm( L_av0[0] );
    = FOR i = 0 to 8:
    = sav0[i] = ( L_av0[i] << shift-3 ) >> 16;
    = NEXT i:

```

Compute partial Σ of dm:

```

L_Σ p = 0;
|= FOR i = 1 to 8:
|= L_Σ p = L_add( L_Σ p, L_mult( rav1[i], sav0[i] ) );
|= NEXT i:

```

Compute the division of partial Σ by sav0[0]:

```

IF ( L_Σ p < 0 ) THEN L_temp = L_sub( 0, L_Σ p );
ELSE L_temp = L_Σ p;

IF ( L_temp == 0 ) THEN
    L_dm = 0;
    shift = 0;
ELSE
    sav0[0] = sav0[0] << 3;
    shift = norm( L_temp );
    temp = ( L_temp << shift ) >> 16;
    IF ( sav0[0] >= temp ) THEN
        divshift = 0;
        temp = div( temp, sav0[0] );
    ELSE
        divshift = 1;
        temp = sub( temp, sav0[0] );
        temp = div( temp, sav0[0] );

    IF( divshift == 1 ) THEN L_dm = 32768;
    ELSE L_dm = 0;

    L_dm = L_add( L_dm, temp ) << 1;
    IF( L_Σ p < 0 ) THEN L_dm = L_sub( 0, L_dm);

```

Re-normalization and final computation of L_dm:

```

L_dm = ( L_dm << 14 );
L_dm = L_dm >> shift;
L_dm = L_add( L_dm, ( rav1[0] << 11 ) );
L_dm = L_dm >> normrav1;

```

Compute the difference and save L_dm:

```

L_temp = L_sub( L_dm, L_lastdm );
L_lastdm = L_dm;
IF ( L_temp < 0 ) THEN L_temp = L_sub( 0, L_temp );
L_temp = L_sub( L_temp, 3277 );

```

Evaluation of the stat flag:

```

IF ( L_temp < 0 ) THEN stat = 1;
ELSE stat = 0;

```

3.5 Periodicity detection

This section just sets the ptch flag needed for the threshold adaptation.

```

temp = add( oldlagcount, veryoldlagcount );
IF ( temp >= 4 ) THEN ptch = 1;
ELSE ptch = 0;

```

3.6 Threshold adaptation

This section uses the variables `e_pvad`, `m_pvad`, `e_acf0` and `m_acf0` computed in section 3.1. It also uses the flags `stat` (see section 3.4) and `ptch` (see section 3.5). It follows the flowchart represented on figure 2.2.

Some constants, represented by a floating point format, are needed and a symbolic name (in capital letter) for their exponent and mantissa is used; table 3-2 lists all these constants with the symbolic names associated and their numerical constant values.

Table 3-2. List of constants

Constant	Exponent	Mantissa
<code>pth</code>	<code>E_PTH = 19</code>	<code>M_PTH = 18750</code>
<code>margin</code>	<code>E_MARGIN = 27</code>	<code>M_MARGIN = 19531</code>
<code>plev</code>	<code>E_PLEV = 20</code>	<code>M_PLEV = 25000</code>

NOTE: Floating point representation of constants used in section 3.6:

```

pth          = 2(E_PTH)x(M_PTH/32768).
margin       = 2(E_MARGIN)x(M_MARGIN/32768).
plev         = 2(E_PLEV)x(M_PLEV/32768).

```

Test if `acf0 < pth`; if yes set `thvad` to `plev`:

```

comp = 0;
IF ( e_acf0 < E_PTH ) THEN comp = 1;
IF ( e_acf0 == E_PTH ) THEN IF ( m_acf0 < M_PTH ) THEN comp = 1;
IF ( comp == 1 ) THEN
    | e_thvad = E_PLEV;
    | m_thvad = M_PLEV;
    | EXIT; /continue with section 3.7/

```

Test if an adaptation is needed:

```

comp = 0;
IF ( ptch == 1 ) THEN comp = 1;
IF ( stat == 0 ) THEN comp = 1;
IF ( tone == 1 ) THEN comp = 1;
IF ( comp == 1 ) THEN
    | adaptcount = 0;
    | EXIT; /continue with section 3.7/

```

Incrementation of `adaptcount`:

```

adaptcount = add( adaptcount, 1 );
IF ( adaptcount <= 8 ) THEN EXIT; /continue with section 3.7/

```

Computation of `thvad-(thvad/dec)`:

```

m_thvad = sub( m_thvad, (m_thvad >> 5 ) );
IF ( m_thvad < 16384 ) THEN
    | m_thvad = m_thvad << 1;
    | e_thvad = sub( e_thvad, 1 );

```

Computation of `pvad*fac`:

```

L_temp = L_add( m_pvad, m_pvad );
L_temp = L_add( L_temp, m_pvad );
L_temp = L_temp >> 1;
e_temp = add( e_pvad, 1 );
IF ( L_temp > 32767 ) THEN
    | L_temp = L_temp >> 1;
    | e_temp = add( e_temp, 1 );
m_temp = L_temp;

```

Test if thvad < pvad*fac:

```

comp = 0;
IF ( e_thvad < e_temp ) THEN comp = 1;
IF ( e_thvad == e_temp ) THEN IF ( m_thvad < m_temp ) THEN comp = 1;

```

Computation of minimum (thvad+(thvad/inc), pvad*fac) if comp = 1:

```

IF ( comp == 1 ) THEN
  Compute thvad +(thvad/inc).
  L_temp = L_add( m_thvad, (m_thvad >> 4 ) );
  IF ( L_temp > 32767 ) THEN
    m_thvad = L_temp >> 1;
    e_thvad = add( e_thvad, 1 );
  ELSE m_thvad = L_temp;
  comp2 = 0;
  IF ( e_temp < e_thvad ) THEN comp2 = 1;
  IF ( e_temp == e_thvad ) THEN IF ( m_temp < m_thvad ) THEN comp2 = 1;
  IF ( comp2 == 1 ) THEN
    e_thvad = e_temp;
    m_thvad = m_temp;

```

Computation of pvad + margin:

```

IF ( e_pvad == E_MARGIN ) THEN
  L_temp = L_add(m_pvad, M_MARGIN);
  m_temp = L_temp >> 1;
  e_temp = add( e_pvad, 1 );
ELSE
  IF ( e_pvad > E_MARGIN ) THEN
    temp = sub( e_pvad, E_MARGIN );
    temp = M_MARGIN >> temp;
    L_temp = L_add( m_pvad, temp );
    IF ( L_temp > 32767 ) THEN
      e_temp = add( e_pvad, 1 );
      m_temp = L_temp >> 1;
    ELSE
      e_temp = e_pvad;
      m_temp = L_temp;
  ELSE
    temp = sub( E_MARGIN, e_pvad );
    temp = m_pvad >> temp;
    L_temp = L_add( M_MARGIN, temp );
    IF ( L_temp > 32767 ) THEN
      e_temp = add( E_MARGIN, 1 );
      m_temp = L_temp >> 1;
    ELSE
      e_temp = E_MARGIN;
      m_temp = L_temp;

```

Test if thvad > pvad + margin:

```

comp = 0;
IF ( e_thvad > e_temp ) THEN comp = 1;
IF ( e_thvad == e_temp ) THEN IF ( m_thvad > m_temp ) THEN comp = 1;

IF ( comp == 1 ) THEN
  e_thvad = e_temp;
  m_thvad = m_temp;

```

Initialize new rvad[0..8] in memory:

```
normrvad = normrav1;
```

```
|= FOR i = 0 to 8:
|= rvad[i] = rav1[i];
|= NEXT i:
```

Set adaptcount to adp + 1:

```
adaptcount = 9;
```

3.7 VAD decision

This section only outputs the result of the comparison between pvad and thvad using the pseudo-floating point representation of thvad and pvad. The values e_pvad and m_pvad are computed in section 3.1 and the values e_thvad and m_thvad are computed in section 3.6.

```
vvad = 0;
IF (e_pvad > e_thvad) THEN vvad = 1;
IF (e_pvad == e_thvad) THEN IF (m_pvad > m_thvad) THEN vvad = 1;
```

3.8 VAD hangover addition

This section finally sets the vad decision for the current frame to be processed.

```
IF ( vvad == 1 ) THEN burstcount = add( burstcount, 1 );
ELSE burstcount = 0;
```

```
IF ( burstcount >= 3 ) THEN
    | hangcount = 5;
    | burstcount = 3;
```

```
vad = vvad;
IF ( hangcount >= 0 ) THEN
    | vad = 1;
    | hangcount = sub( hangcount, 1 );
```

3.9 Periodicity updating

This section must be delayed until the LTP lags are computed by the RPE-LTP algorithm. The LTP lags called N_c in the speech encoder are renamed lags[0..3] (index 0 for the first sub-segment of the frame, 1 for the second and so on).

Loop on sub-segments for the frame:

```
lagcount = 0;

= FOR i = 0 to 3:
= Search the maximum and minimum of consecutive lags.
= IF ( oldlag > lags[i] ) THEN
=                               | minlag = lags[i];
=                               | maxlag = oldlag;
= ELSE
=                               | minlag = oldlag;
=                               | maxlag = lags[i] ;
=
= Compute smalllag (modulo operation not defined ):
=
= smalllag = maxlag;
== | FOR j = 0 to 2:
== |   IF (smalllag >= minlag) THEN smalllag =sub( smalllag, minlag);
== |   NEXT j;
=
= Minimum of smalllag and minlag - smalllag:
=
= temp = sub( minlag, smalllag );
= IF ( temp < smalllag ) THEN smalllag = temp;
= IF ( smalllag < 2 ) THEN lagcount = add( lagcount, 1 );
= Save the current LTP lag.
= oldlag = lags[i];
= NEXT i:
```

Update the veryoldlagcount and oldlagcount:

```
veryoldlagcount = oldlagcount;
oldlagcount      = lagcount;
```

3.10 Tone detection

This section computes the tone variable needed for the threshold adaptation. tone is only calculated for the VAD in the downlink. In the uplink VAD tone=0.

To reduce delay, this section should be calculated after the processing of the current speech encoder frame.

3.10.1 Windowing

This section applies a Hanning window to the input frame sof[0..159] to form the output frame sof_h[0..159]. The input frame is the current offset compensated signal frame calculated in the RPE-LTP codec. The array of constants hann[i] is defined in table 3-2.

Multiply signal frame by Hanning window:

```
== FOR i = 0 to 79:
|   sofh[i] = mult_r( sof[i], hann[i] );
|   sofh[159-i] = mult_r( sof[159-i], hann[i] );
== NEXT i;
```

3.10.2 Autocorrelation

This section computes the autocorrelation vector `L_acfh[0..5]` from the windowed input frame `sofh[0..159]`. The input frame must be scaled in order to avoid an overflow situation. This section is identical to the one used in the RPE-LTP algorithm, with the exception that only five autocorrelation values are calculated.

Dynamic scaling of the array `sofh[0..159]`:

Search for the maximum:

```
smax = 0;

|== FOR k = 0 to 159:
|   temp = abs( sofh[k] );
|   IF ( temp > smax ) THEN smax = temp;
|== NEXT k;
```

Computation of the scaling factor:

```
IF ( smax == 0 ) THEN scalauto = 0;
ELSE scalauto = sub( 4, norm( smax << 16));
```

Scaling of the array `sofh[0..159]`:

```
IF ( scalauto > 0 ) THEN
|   temp = 16384 >> sub( scalauto,1);
|   == FOR k = 0 to 159:
|     sofh[k] = mult_r( sofh[k], temp);
|   == NEXT k;
```

Compute the L-ACF[.]:

```
|== FOR k=0 to 4:
|   L_acfh[k] = 0;
|==== FOR i=k to 159:
|   L_temp = L_mult( sofh[i], sofh[i-k] );
|   L_acfh[k] = L_add( L_acfh[k], L_temp );
|==== NEXT i:
|== NEXT k;
```

3.10.3 Computation of the reflection coefficients

This section calculates the reflection coefficients `rc[1..4]` from the input array `L_acfh[0..4]`. This procedure is identical to the one in section 3.3.1 and the RPE-LTP codec, with the exception that only four reflection coefficients are calculated.

Schur recursion with 16 bits arithmetic:

```
IF( L_acfh[0] == 0 ) THEN
|   == FOR i = 1 to 4:
|     rc[i] = 0;
|   == NEXT i:
|   EXIT; /continue with section 3.10.4/
temp = norm( L_acfh[0] );
|== FOR k=0 to 4:
|   sacf[k] = ( L_acfh[k] << temp ) >> 16;
|== NEXT k;
```

Initialize array `P[.]` and `K[.]` for the recursion:

```
|== FOR i=1 to 3:
|   K[5-i] = sacf[i];
|== NEXT i:

|== FOR i=0 to 4:
|   P[i] = sacf[i];
|== NEXT i;
```

Compute reflection coefficients:

```

== FOR n=1 to 4:
    IF( P[0] < abs( P[1] ) ) THEN
        rc[n] = div( abs( P[1] ), P[0] );
        IF ( P[1] > 0 ) THEN rc[n] = sub( 0, rc[n] );
        IF ( n == 4 ) THEN EXIT; /continue with section 3.10.4/

        Schur recursion:

        P[0] = add( P[0], mult_r( P[1], rc[n] ) );
==== FOR m=1 to 4-n:
    P[m] = add( P[m+1], mult_r( K[5-m], rc[n] ) );
    K[5-m] = add( K[5-m], mult_r( P[m+1], rc[n] ) );
==== NEXT m:
== NEXT n:

```

3.10.4 Filter coefficient calculation

This section calculates the direct form filter coefficients a[1..2] from the reflection coefficients rc[1..4].

Step-up procedure to obtain the a[1..2]:

```

temp = rc[1] >> 2;
a[1] = add( temp, mult_r( rc[2], temp ) );
a[2] = rc[2] >> 2;

```

3.10.5 Pole Frequency Test

This section uses the direct form filter coefficients a[0..2] to determine the pole frequency of the second order LPC analysis. If the pole frequency is less than 385 Hz tone is set to 0 and section 3 terminates.

```

L_den = L_mult ( a[1], a[1] );

```

```

L_temp = a[2] << 16;
L_num = L_sub ( L_temp, L_den );

```

If pole is not complex then exit:

```

IF ( L_num <= 0 ) THEN
    tone = 0;
    EXIT; /section 3 complete/

```

If pole frequency is less than 385 Hz then exit:

```

IF ( a[1] < 0 ) THEN
    temp = L_den >> 16;
    L_den = L_mult ( temp, 3189 );
    L_temp = L_sub ( L_num, L_den );
    IF ( L_temp < 0 ) THEN
        tone = 0;
        EXIT; /section 3 complete/

```

3.10.6 Prediction gain test

This section uses the reflection coefficients $rc[1..4]$ to calculate the prediction gain. If the prediction gain is greater than 13.5 dB then tone is set to 1 otherwise tone is set to 0.

Calculate normalised prediction error:

```
prederr = 32767;

== FOR i=1 to 4
  temp = mult ( rc[i], rc[i] );
  temp = sub ( 32767, temp);
  prederr = mult( prederr, temp );
== NEXT i;
```

Test if prediction error is smaller than threshold:

```
temp = sub ( prederr, 1464 );

IF ( temp < 0 ) THEN tone = 1;
ELSE tone = 0;
```

Table 3-2. Values of the Hanning window array hann[i].

i	hann	i	hann	i	hann	i	hann
0	0	20	4856	40	16545	60	28139
1	12	21	5325	41	17192	61	28581
2	51	22	5811	42	17838	62	29003
3	114	23	6314	43	18482	63	29406
4	204	24	6832	44	19122	64	29789
5	318	25	7365	45	19758	65	30151

4 Digital test sequences

This chapter provides information on the digital test sequences that have been designed to help the verification of implementations of the Voice Activity Detector. Copies of these sequences are available (see Annex 2).

4.1 Test configuration

The VAD must be tested in conjunction with the speech encoder defined in GSM 06.10. The test configuration is shown in figure 4-1. The input signal to the speech encoder is the $sop[...]$ signal as defined in GSM 06.10 table 5.1. The relevant parameters produced by the speech encoder are input to the VAD algorithm to produce the VAD output. This output has to be checked against some reference files.

The file format of the encoder output parameters given in GSM 06.10 table 5.1 is extended to carry the VAD information.

The VAD information is placed in the unused bit 15 (MSB) of the first encoded parameter:

```
LAR(1): bit 15 := 1 if VAD on  
        bit 15 := 0 if VAD Off
```

Furthermore, in order to facilitate approval testing over the air interface, the SP flag generated by the TX DTX handler (see GSM 06.31) on the basis of the VAD flag is placed in the MSB position of the second encoded parameter:

```
LAR(2): bit 15 := 1 if SP on  
        bit 15 := 0 if SP off
```

The output file will also contain the SID codeword and the comfort noise parameters as described in GSM 06.12 and GSM 06.31.

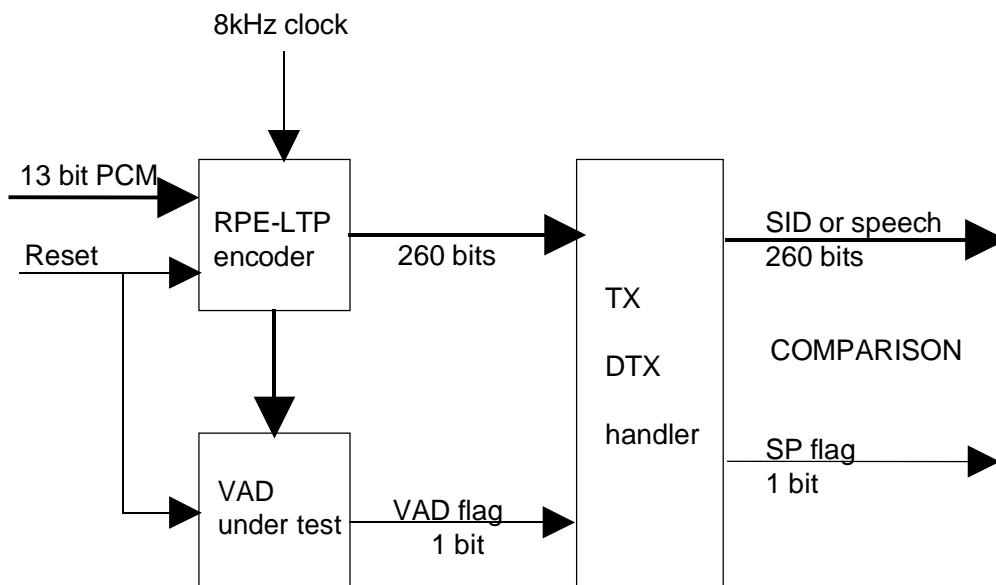

Figure 4-1: VAD test configuration

4.2 Test sequences

The test sequences are described in detail in Annex 2.

Annex 1 (informative): Simplified block filtering operation

Consider an 8th order transversal filter with filter coefficients $a_0..a_8$, through which a signal is being passed, the output of the filter being:

$$s'n := - \sum_{i=0}^8 a_i s_{n-i} \quad [1]$$

If we apply block filtering over 20ms segments, then this equation becomes:

$$s'n := - \sum_{i=0}^8 a_i s_{n-i} \quad ; n = 0..167 \quad [2]$$

$$; 0 \leq n-i \leq 159$$

If the energy of the filtered signal is then obtained for every 20 ms segment, the equation for this is:

$$P_{vad} := \sum_{n=0}^{167} \left(- \sum_{i=0}^8 a_i s_{n-i} \right)^2 ; 0 \leq n-i \leq 159 \quad [3]$$

We know that (see GSM 06.10, section 3.1.4):

$$ACF[i] := \sum_{n=0}^{159} s_n s_{n-i} \quad ; i = 0..8 \quad [4]$$

$$; 0 \leq n-i \leq 159$$

If equation [3] is expanded and $ACF[0]..ACF[8]$ are substituted for s_n then we arrive at the equations:

$$P_{vad} := r[0]ACF[0] + 2 \sum_{i=1}^8 r[i]ACF[i] \quad [5]$$

Where:

$$r[i] := \sum_{k=0}^{8-i} a_k a_{k+i} \quad ; i = 0..8 \quad [6]$$

Annex 2 (informative): Description of digital test sequences

A.2.1 Test sequences

The VAD algorithm uses results from the full rate speech encoder defined in GSM 06.10. In the testing of the VAD, it is assumed that the relevant speech encoder functions have been verified by the test sequences defined in GSM 06.10.

The five types of input sequences are briefly described below.

Spectral comparison

The two kinds of statements of the spectral comparison algorithm (section 3.4), arithmetic statements and control statements, are tested by separate test sequences.

Arithmetic statements:

spec_a1.*
spec_a2.*

Control statements

spec_c1.*
spec_c2.*
spec_c3.*
spec_c4.*

Threshold adaptation

There are two types of tests to verify the threshold adaptation described in section 3.6:

adapt_i1.*
adapt_i2.*

The initial test sequences test the acf0 and VAD decision. A fault in the VAD decision will cause all the other sequences to fail, so it is recommended that this test is run before all other tests.

adapt_m1.*
adapt_m2.*

The main test sequences will check the basic threshold adaptation mechanism.

Periodicity detection

pitch1.*
pitch2.*

These sequences check the periodicity detection algorithm described in section 3.5.

Tone detection

The tone detector test sequences are only required for downlink VAD implementations. There are Three types of test to verify the tone detection algorithm described in section 3.10. The first test sequence tests the operation of the tone detector by means of a frequency sweep:

freq_sw.*

The following sequences test the second order pole frequency calculation within the tone detector:

pole1.*
pole2.*

"Safety" and initialisation

safety.*

This sequence checks that safety tests have been implemented to prevent zero values being passed to the norm function. It checks the functions described in the Adaptive Filtering and Energy Computation section (section 3.1), and the Predictor Values Computation (section 3.3). This sequence also checks the initialization of thvad and the rvad array.

Real speech

good_sp.*
bad_sp.*

Because the test sequences cannot be guaranteed to find every possible error, there is a small possibility that an implementation of the correct output for test sequences, but fail with real speech. Because of this, an extra set of sequences are included that consist of barely detectable speech and very clean speech.

There are 3 different file extensions:

- *.inp: speech encoder input sequences, binary files
- *.vad: output flag of the VAD algorithm, ASCII files
- *.cod: TX DTX handler output sequences, binary files for comparison with VAD/DTX handler output.

The *.cod files contain speech coder output information in the format described in section 4.

It should be noted that there is no requirement in GSM 06.12 for a bit exact implementation of the averaging procedure to calculate the "LAR" and "xmax" parameters in the SID frames. Different implementations are allowed.

The algorithms used for the calculation of the LAR and xmax parameters of the SID frames are therefore reproduced below:

LAR averaging:

```

FOR i = 1 to 8:
  L_Temp = 2; /* const. for rounding*/
  FOR n = 1 to 4:
    L_Temp1 = LAR[j-n](i); /*conversion 16 --> 32 bit*/
    L_Temp = L_Add( L_Temp , L_Temp1 );
  NEXT n
  L_Temp = L_temp >> 2;
  mean (LAR(i)) = L_Temp; /*conversion 32 --> 16 bit*/
NEXT i;

```

xmax averaging

```

L_Temp = 8; /* const. for rounding*/

FOR n = 1 to 4:
  FOR i = 1 to 4:
    L_Temp1 = xmax[j-n](i); /*conversion 16 --> 32 bit*/
    L_Temp = L_Add( L_Temp , L_Temp1 );
  NEXT i
NEXT n

L_Temp = L_Temp >> 4;

mean (xmax) = L_Temp; /*conversion 32 --> 16 bit*/

```

A.2.2 File format description

All the *.inp and *.cod files are written in binary using 16 bit words, while all *.vad files are written in ASCII format. The sizes of the files are shown in table A2-1, A2-2 and A2-3. The detailed format of the *.inp and *.cod files is in accordance with the descriptions given in GSM 06.10 section 5.

The diskette is formatted according to the high capacity (1.2 Mb) specifications for MS-DOS PC-AT compatible computers.

=====		

Annex 3 (informative): VAD performance

In optimising a VAD a difficult trade-off has to be made between speech clipping which reduces the subjective performance of the system, and the average activity factor. The benefit of DTX is increased as the average activity factor is reduced. However, in general, a reduction of the activity will be associated with a greater risk for audible speech clipping.

In the optimisation process, great emphasis has been placed on avoiding unnecessary speech clipping. However, it has been found that a VAD with virtually no audible clipping would result in a very high activity and very little DTX advantage.

The VAD specified in this technical specification introduces audible and possibly objectionable clipping in certain cases, mainly with low input levels. However, a comprehensive evaluation programme consisting of about 600 individual conversations conducted in a wide range of realistic conditions, it was found that about 90% of the conversations were free from objectionable clipping.

The voice activity performance of the VAD is summarised in table A3-1. The activity figures are averages of a large number of conversations covering factors like different talkers, noise characteristics and locations. It should be noted that the actual activity of a particular talker in a specific conversation may vary considerably relative to the averages given. This is due both to the variation in talker behaviour as well as to the level dependency of the VAD (the channel activity has been found to decrease by about 0.5 points of percentage per dB level reduction). However, as mentioned above, a decreased speech input level increases the risk of objectionable speech clipping.

All the values given are activity figures, i.e. the % of time the radio channel has to be on.

Table A.3-1. Summary of channel activity

Telephone instrument:	Situation:	Typical channel activity factor:
Handset	Quiet location	55 %
Handset	Moderate office noise with voice interference	60 %
Handset	Strong voice interference (eg airport/railway station)	65-70 %
Handsfree/handset	Variable vehicle noise	60 %

Annex 4 (informative): Pole frequency calculation

This Annex describes the algorithm used to determine whether the pole frequency for a second order analysis of the signal frame is less than 385 Hz.

The filter coefficients for a second order synthesis filter are calculated from the first two unquantized reflection coefficients RC[1..2] obtained from the speech encoder. This is done using the routine described in section 3.10.4. If the filter coefficients a[0..2] are defined such that the synthesis filter response is given by:

$$H(z) = 1 / (a[0] + a[1]z^{-1} + a[2]z^{-2}) \quad [1]$$

Then the positions of the poles in the Z-plane are given by the solutions to the following quadratic:

$$a[0]z^2 + a[1]z + a[2] = 0, \quad a[0] = 1 \quad [2]$$

The positions of the poles, z, are therefore:

$$z = re \pm j \sqrt{im}, \quad j^2 = -1 \quad [3]$$

where:

$$re = - a[1] / 2 \quad [4]$$

$$im = (4*a[2] - a[1]^2) / 4 \quad [5]$$

If im is negative then the poles lie on the real axis of the Z-plane and the signal is not a tone and the algorithm terminates. If re is negative then the poles lie in the left hand side of the Z-plane and the frequency is greater than 2000 Hz and the prediction error test can be performed.

If im is positive and re is positive then the poles are complex and lie in the right hand side of the Z-plane and the frequency in Hz is related to re and im by the expression:

$$freq = \arctan (\sqrt{im}/re) * 4000 / \pi \quad [6]$$

Having ensured that both im and re are positive, the test for a dominant frequency less than 385 Hz can be derived by substituting Equations 4 and 5 into Equation 6 and re-arranging:

$$(4*a[2] - a[1]^2) / a[1]^2 < \tan(\pi*385/4000) \quad [7]$$

or

$$(4*a[2] - a[1]^2) / a[1]^2 < 0.0973 \quad [8]$$

If this test is true then the signal is not a tone and the algorithm terminates, otherwise the prediction error test is performed.
