Foreword

This draft European Telecommunication Standard (ETS) has been produced by the Special Mobile Group (SMG) Technical Committee of the European Telecommunications Standards Institute (ETSI) and is now submitted for the Public Enquiry phase of the ETSI standards approval procedure.

This draft ETS introduces the Enhanced Full Rate (EFR) speech traffic channels within the digital cellular telecommunications system.

This draft ETS corresponds to GSM technical specification, GSM 06.51, version 5.0.0

Proposed transposition dates	
Date of latest announcement of this ETS (doa):	3 months after ETSI publication
Date of latest publication of new National Standard or endorsement of this ETS (dop/e):	6 months after doa
Date of withdrawal of any conflicting National Standard (dow):	6 months after doa

Blank page

1 Scope

This draft European Telecommunication Standard (ETS) is an introduction to GSM 06.60, GSM 06.61, GSM 06.62, GSM 06.81 and GSM 06.82 ETSs dealing with the speech processing functions in the enhanced full rate channel of the GSM system. A general overview of the speech processing functions is given, with reference to the ETSs where each function is specified in detail.

2 Normative references

This ETS incorporates by dated and undated reference, provisions from other publications. These normative references are cited at the appropriate places in the text and the publications are listed hereafter. For dated references, subsequent amendments to or revisions of any of these publications apply to this ETS only when incorporated in it by amendment or revision. For undated references, the latest edition of the publication referred to applies.

3 Definitions and abbreviations

3.1 Definitions

Definition of terms used in this ETS can be found in GSM 06.60, GSM 06.61, GSM 06.62, GSM 06.81 and GSM 06.82.

3.2 Abbreviations

For the purpose of this ETS, the following abbreviations apply.

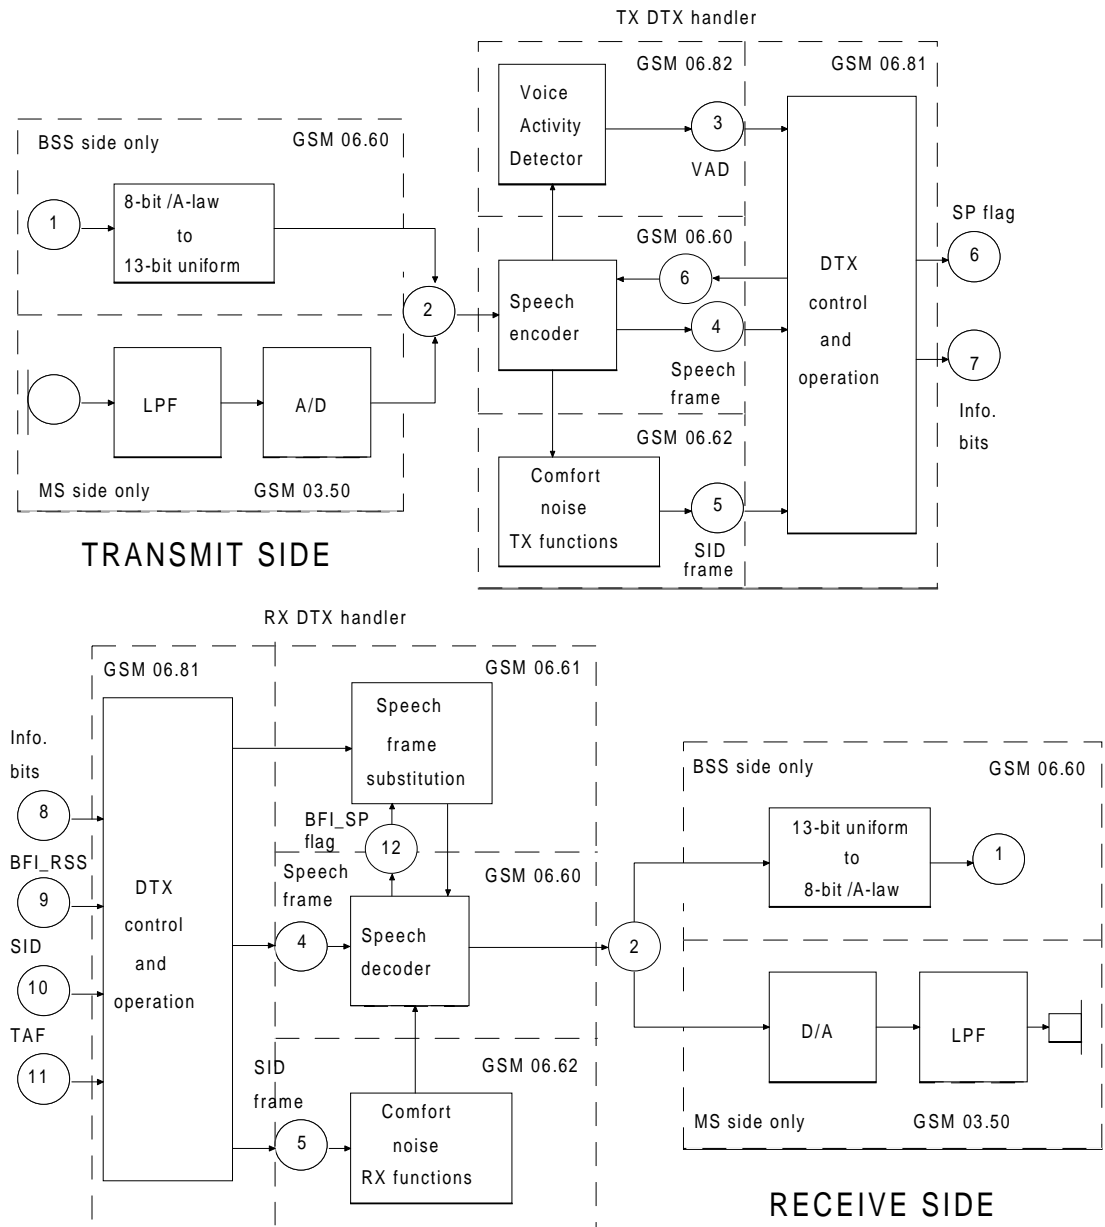

ACELP	Algebraic Code Excited Linear Prediction
BFI_RSS	Bad Frame Indication from Radio Sub System
BFI_SP	Bad Frame Indication from Speech Decoder
BSS	Base Station System
CCITT	Comité Consultatif International Télégraphique et Téléphonique
DTX	Discontinuous Transmission
ETS	European Telecommunication Standard
GSM	Global System for Mobile communications
MS	Mobile Station
PCM	Pulse Code Modulated
PLMN	Public Land Mobile Network
PSTN	Public Switched Telephone Network
RF	Radio Frequency
RX	Receive
RSS	Radio SubSystem
SACCH	Slow Associated Control CHannel
SID	Silence Descriptor
SP flag	SPeech flag
TAF	Time Alignment Flag
TX	Transmit

For abbreviations not given in this subclause, see GSM 01.04.

4 General

Figure 1 presents a reference configuration where the various speech processing functions are identified. In this figure, the relevant ETSs for each function are also indicated.

In figure 1, the audio parts including analogue to digital and digital to analogue conversion are included, to show the complete speech path between the audio input/output in the Mobile Station (MS) and the digital interface of the PSTN. The detailed specification of the audio parts are contained in GSM 03.50 (ETS 300 540). These aspects are only considered to the extent that the performance of the audio parts affect the performance of the speech transcoder.

- 1) 8-bit /A-law PCM (CCITT rec G.711), 8000 samples/s
- 2) 13-bit uniform PCM, 8000 samples/s
- 3) Voice Activity Detector (VAD) flag
- 4) Encoded speech frame, 50 frames/s, 260 bits/frame
- 5) Silence Descriptor (SID) frame, 260 bits/frame
- 6) SP flag, indicates whether information bits are speech or SID information
- 7) Information bits delivered to the radio subsystem
- 8) Information bits received from the radio subsystem
- 9) Bad Frame Indication (BFI_RSS) flag from Radio Sub System
- 10) Silence Descriptor (SID) flag
- 11) Time Alignment Flag (TAF), marks the position of the SID frame within the Slow Associated Control Channel (SACCH) multiframe
- 12) Bad Frame Indication (BFI_SP) flag from speech decoder

Figure 1: Overview of audio processing functions

5 Enhanced speech channel transcoding

As shown in figure 1, the speech encoder takes its input as a 13-bit uniform Pulse Code Modulated (PCM) signal either from the audio part of the Mobile Station or on the network side, from the Public Switched Telephone Network (PSTN) via an 8-bit/A-law to 13-bit uniform PCM conversion. The encoded speech at the output of the speech encoder is delivered to the channel coding function defined in GSM 05.03 to produce an encoded block consisting of 456 bits leading to a gross bit rate of 22.8 kbit/s.

In the receive direction, the inverse operations take place. GSM 06.60 describes the detailed mapping between input blocks of 160 speech samples in 13-bit uniform PCM format to encoded blocks of 260 bits and from encoded blocks of 260 bits to output blocks of 160 reconstructed speech samples. The sampling rate is 8000 sample/s leading to a bit rate for the encoded bit stream of 13 kbit/s. The coding scheme is the so-called Algebraic Code Excited Linear Prediction, hereafter referred to as ACELP.

GSM 06.60 describes the codec and GSM 06.53 defines the C code, thus enabling the verification of compliance to GSM 06.60 to a high degree of confidence by use of a set of digital test sequences given in GSM 06.54.

6 Enhanced speech channel discontinuous transmission (DTX)

During a normal phone conversation, the participants alternate so that, on the average, each direction of transmission is occupied about 50% of the time. Discontinuous transmission (DTX) is a mode of operation where the transmitters are switched on only for those frames which contain useful information. This may be done for the following two purposes:

- 1) In the MS, battery life will be prolonged or a smaller battery could be used for a given operational duration.
- 2) The average interference level over the air interface is reduced, leading to better Radio Frequency (RF) spectrum efficiency.

The overall DTX mechanism is implemented in the DTX handlers (Transmit (TX) and Receive (RX)) described in GSM 06.81 and requires the following functions:

- a Voice Activity Detector (VAD) on the TX side, see GSM 06.82;
- evaluation of the background acoustic noise on the TX side, in order to transmit characteristic parameters to the RX side, see GSM 06.62;
- generation of comfort noise on the RX side during periods where the radio transmission is turned off, see GSM 06.62.

The transmission of comfort noise information to the RX side is achieved by means of a Silence Descriptor (SID) frame. The SID frame is transmitted at the end of speech bursts and serves as an end of speech marker for the RX side. In order to update the comfort noise characteristics at the RX side, SID frames are transmitted at regular intervals also during speech pauses. This also serves the purpose of improving the measurement of the radio link quality by the Radio SubSystem (RSS).

The DTX handlers interwork with the RSS using flags. The RSS is in control of the actual transmitter keying on the TX side, and performs various pre-processing functions on the RX side. This is described in GSM 06.81.

The speech flag (SP) indicates whether information bits are speech or SID information. The SP flag is calculated from the VAD flag by the TX DTX handler. When SID information is transmitted (SP="0") the operation of the speech encoder is modified to reduce the remaining computation for that frame. This is described in GSM 06.62.

7 Enhanced speech channel voice activity detection (VAD)

The enhanced full rate VAD function is described in GSM 06.82.

The input to the VAD is a set of parameters computed by the enhanced full rate speech encoder defined in GSM 06.60. The VAD uses this information to decide whether each 20 ms speech coder frame contains speech or not. Note that the VAD flag is an input to TX DTX handler and does not control the transmitter keying directly.

GSM 06.82 describes the VAD algorithm and GSM 06.53 defines the C code. The verification of compliance to GSM 06.82 is achieved by use of digital test sequences (see GSM 06.54) applied to the same interface as the test sequences for the speech codec.

8 Enhanced speech channel comfort noise insertion

The enhanced full rate noise comfort insertion function is described in GSM 06.62.

When switching the transmission on and off during DTX operation, the effect would be a modulation of the background noise at the receiving end, if no precautions were taken. When transmission is on, the background noise is transmitted together with the speech to the receiving end. As the speech burst ends, the connection is off and the perceived noise would drop to a very low level. This step modulation of noise may be perceived as annoying and reduce the intelligibility of speech, if presented to a listener without modification.

This "noise contrast effect" is reduced in the GSM system by inserting an artificial noise, termed comfort noise, at the receiving end when speech is absent.

The comfort noise processes are as follows:

- the evaluation of the acoustic background noise in the transmitter;
- the noise parameter encoding (SID frames) and decoding;
- and the generation of comfort noise in the receiver.

The comfort noise processes and the algorithm for updating the noise parameters during speech pauses are defined in detail in GSM 06.62.

The comfort noise mechanism is based on the enhanced full rate speech codec defined in GSM 06.60.

9 Enhanced speech channel lost speech frame substitution and muting

The enhanced full rate speech frame substitution and muting function is described in GSM 06.61.

In the receiver, frames may be lost due to transmission errors or frame stealing. GSM 06.61 describes the actions to be taken in these cases, both for lost speech frames and for lost SID frames in DTX operation.

In order to mask the effect of an isolated lost frame, the lost speech frame is substituted by a predicted frame based on previous frames. Insertion of silence frames is not allowed. For several subsequent lost frames, a muting technique shall be used to indicate to the listener that transmission has been interrupted.

10 Enhanced full rate codec homing

The GSM enhanced full rate speech transcoder, VAD, DTX system and comfort noise parts of the audio processing functions (see figure 1) are defined in bit exact arithmetic. Consequently, they shall react on a given input sequence always with the corresponding bit exact output sequence, provided that the internal state variables are also always exactly in the same state at the beginning of the experiment.

The input test sequences provided in GSM 06.54 shall force the corresponding output test sequences, provided that the tested modules are in their home-state when starting.

The modules may be set into their home states by provoking the appropriate homing-functions.

NOTE: This is normally done during reset (initialisation of the codec).

Special inband signalling frames (encoder-homing-frame and decoder-homing-frame) described in GSM 06.60 have been defined to provoke these homing-functions also in remotely placed modules.

This mechanism is specified to support three main areas:

- type approval of mobile terminal equipment;
- type approval of infrastructure equipment;
- remote control and testing for operation and maintenance.

At the end of the first received homing frame, the audio functions that are defined in a bit exact way shall go into their predefined home states. The output corresponding to the first homing frame is dependent on the codec state when the frame was received. Any consecutive homing frames shall produce corresponding homing frames at the output.
