## Foreword

This European Telecommunication Standard (ETS) has been produced by the Special Mobile Group (SMG) Technical Committee (TC) of the European Telecommunications Standards Institute (ETSI).

This ETS specifies the Radio Link Protocol (RLP) for data transmission over within the digital cellular telecommunications system. This ETS is a GSM technical specification version 5.

The ETS from which this Phase 2+ ETS has evolved is Phase 2 GSM ETS 300 563 + Amendment 1 (GSM 04.22 version 4.4.0).

The specification from which this ETS has been derived was originally based on CEPT documentation, hence the presentation of this ETS may not be entirely in accordance with the ETSI rules.

Transposition dates						
Date of adoption:	4 April 1997					
Date of latest announcement of this ETS (doa):	31 August 1997					
Date of latest publication of new National Standard or endorsement of this ETS (dop/e):	28 February 1998					
Date of withdrawal of any conflicting National Standard (dow):	28 February 1998

## 1 Scope

This European Telecommunication Standard (ETS) specifies the Radio Link Protocol (RLP) for data transmission over the GSM PLMN. RLP covers the Layer 2 functionality of the ISO OSI Reference Model (IS 7498). It is based on ideas contained in IS 3 309, IS 4 335 and IS 7 809 (HDLC of ISO) as well as CCITT X.25 and Q.92x (LAP-B and LAP-D of CCITT, respectively.) RLP has been tailored to the special needs of digital radio transmission. RLP provides to its users the OSI Data Link Service (IS 8 886).

RLP is intended for use with non-transparent data-transfer. Protocol conversion may be provided for a variety of protocol configurations. Those foreseen immediately are:

- Character-mode protocols using start-stop transmission (IA5);
- X.25 LAP-B.

For reasons of better presentation, material about protocol conversion has been placed within those Specifications concerned with the relevant Terminal Adaptors, i.e. GSM 07.02 for the asynchronous case and GSM 07.03 for the synchronous case. Care must be taken that that material also applies to Interworking Functions; see GSM 09.04 - 09.07.

## 2 Normative references

This ETS incorporates by dated and undated reference, provisions from other publications. These normative references are cited at the appropriate places in the text and the publications are listed hereafter. For dated references, subsequent amendments to or revisions of any of these publications apply to this ETS only when incorporated in it by amendment or revision. For undated references, the latest edition of the publication referred to applies.

#### 2.1 Definitions and abbreviations

For the purposes of this ETS, the following definitions apply:

**command:** An instruction represented in the RLP header, causing the receiving RLP entity to execute a specific function.

frame check sequence: A field of redundant information based on a cyclic code, used for error detection.

**I + S frame:** An RLP frame that is used for user information transfer, carrying supervisory information piggyback.

**improper frame:** An RLP frame having an FCS error or having a header the contents of which is inconsistent with this ETS.

**non-transparent:** In PLMN data transmission, a configuration where at layer 2, protocol information of the fixed network is mapped on RLP elements, and vice versa.

**piggybacking:** Means by which one and the same frame can carry both user information and RLP related supervisory information.

**response:** A reply represented in the RLP-header, by which the sending RLP entity reports back about its status.

**RLP frame:** A sequence of contiguous bits, representing an RLP procedural element.

**RLP header:** That part of an RLP frame that encodes either a command or a response, located at the beginning of the RLP frame.

**S frame:** An RLP frame that contains supervisory information in the absence of user information.

**transparent:** In PLMN data transmission, a configuration where at layer 2 (and also at the layers above) no protocol conversion takes place.

U frame: An RLP frame that contains unnumbered protocol control information.

Abbreviations used in this ETS are listed in GSM 01.04 [1].

#### 3 Introduction

RLP makes use of an underlying FEC (Forward Error Correction) mechanism. For RLP to perform adequately it is assumed that the basic radio channel together with FEC provides for a block error rate of less than 10 %, where a block consists of 240 bits.

RLP frames are sent in strict alignment with the radio transmission (for details, see GSM 04.21). RLP frames are of fixed size of 240 bits. Whenever such a 240 bit frame is to be sent, the RLP entity has to provide the necessary protocol information to be contained in it. Provision is made for discontinuous transmission (DTX).

RLP spans from the Mobile Station (MS) to the interworking function (IWF), located at the nearest Mobile Switching Centre (MSC), or beyond. Depending on the exact location of the IWF, handover of the MS may result in link-reset or even total loss of the connection.

In the terminology of HDLC, RLP is used in a balanced configuration, employing asynchronous operation, i.e. either station has the right to set-up, reset, or disconnect a link at any time. Procedural means are provided for to deal with contentious situations, should they ever occur.

RLP is full-duplex in the sense that it allows for information to be transferred in both directions simultaneously.

#### Page 10 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

## 4 Frame structure

#### 4.1 Basic frame structure

An RLP-frame has a fixed length of 240 bits consisting of a header (16 bits), an information field (200 bits), and an FCS (frame check sequence) field (24 bits). As a benefit of using strict alignment with underlying radio transmission there is no need for frame delimiters (like flags etc.) in RLP. In consequence, there is no "bit-stuffing" necessary in order to achieve code transparency. Frames cannot be aborted while being transmitted.

Header	Information	FCS
16 bit	200 bit	24 bit

#### Figure 1: Frame structure

#### 4.2 RLP header

An RLP-header carries one of three types of control information, the first being unnumbered protocol control information (U frames), the second being supervisory information (S frames), the third being user information carrying supervisory information piggybacked (I + S frames).

#### 4.3 Order of transmission

The header, as defined in subclause 5.2, shall be transmitted from left to right. The FCS shall be transmitted commencing with the highest order term. The order of bit transmission for the information field is from left to right.

#### 4.4 Frame check sequence

The FCS shall be the ones complement of the modulo 2 sum of:

a) the remainder of:

 $x^{216} \left(x^{23} + x^{22} + x^{21} + x^{20} + x^{19} + x^{18} + x^{17} + x^{16} + x^{15} + x^{14} + x^{13} + x^{12} + x^{11} + x^{10} + x^9 + x^8 + x^7 + x^6 + x^5 + x^4 + x^3 + x^2 + x + 1\right)$ 

divided modulo 2 by the generator polynomial:

 $x^{24} + x^{23} + x^{21} + x^{20} + x^{19} + x^{17} + x^{16} + x^{15} + x^{13} + x^8 + x^7 + x^5 + x^4 + x^2 + 1$ 

and

b) the remainder of the division modulo 2 by the generator polynomial:

 $x^{24} + x^{23} + x^{21} + x^{20} + x^{19} + x^{17} + x^{16} + x^{15} + x^{13} + x^8 + x^7 + x^5 + x^4 + x^2 + 1$ 

of the product of  $x^{24}$  by the content of the frame, excluding the FCS field. (The first bit transmitted corresponds to the highest order term.)

Implementation note: As a typical implementation, at the transmitter, the initial content of the register of the device computing the remainder of the division is pre-set to all ones and is then modified by division by the generator polynomial (as described above) of the header and information field; the ones complement of the resulting remainder is transmitted as the 24 bit FCS sequence.

At the receiver, the initial content of the register of the device computing the remainder is pre-set to all ones. The final remainder after multiplication by  $x^{24}$  and then division (modulo 2) by the generator polynomial:

 $x^{24} + x^{23} + x^{21} + x^{20} + x^{19} + x^{17} + x^{16} + x^{15} + x^{13} + x^8 + x^7 + x^5 + x^4 + x^2 + 1$ 

of the serial incoming protected bits and the FCS will be:

0 1 1 0 1 1 0 1 1 0 0 0 1 0 0 1 0 0 1 1 0 0 0 0 (x<sup>23</sup> to x<sup>0</sup>, resp.)

in the absence of transmission errors.

#### 5 Elements and procedure

#### 5.1 Modes

An RLP entity can be in one of two modes:

- Asynchronous Balanced Mode (ABM).
- Asynchronous Disconnected Mode (ADM).

#### 5.1.1 Asynchronous Balanced Mode (ABM)

In ABM, which is the data link operational mode, either RLP entity may send commands at any time and may initiate response frame transmission without receiving explicit permission to do so from the other RLP-station. In ABM, frames shall be used for information field transfer and/or to indicate status changes in the RLP-station.

#### 5.1.2 Asynchronous Disconnected Mode (ADM)

In ADM, which is the data-link non-operational mode, the RLP entity shall be logically disconnected from the data link and shall, therefore, neither transmit nor accept numbered information frames.

The RLP entity shall, however, be permitted to transmit and accept NULL, DM, UI, TEST and XID frames. Either RLP entity can issue an SABM command at any time, in order to terminate the ADM state. In that case, entrance of the ABM state will be indicated by a UA response from the opposite station. If the opposite station is not able to enter ABM, it will indicate this by a DM response. All commands other than those mentioned above and any unsolicited response will be ignored in ADM under all circumstances.

## Page 12 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

#### 5.2 Header and parameters

The formats defined for the header are listed in figure 2 below.

#### 5.2.1 Generally used bits

NOTE:

C/R = COMMAND/RESPONSE BIT X = DON'T CARES N(S): Bit 4 low order bit

#### Figure 2: Header format

## 5.2.1.1 Command/response bit, C/R

The C/R-bit is used to indicate whether the frame is a command or response frame and whether the P/F-bit is to be interpreted as a poll or final bit, resp. For commands, the C/R bit shall be set to "1", for responses it shall be set to "0".

## 5.2.1.2 Poll/Final bit, P/F

The P/F-bit is used to mark a special instance of command/response exchange. With a command, it is called the P-bit, with a response, it is called the F-bit. In any one direction, only one P/F-bit exchange may be outstanding at any time. A response with the F-bit set to "1" shall always reflect the latest receive status of the RLP entity.

A P/F-bit exchange always starts with a command frame with the P-bit set to "1", which shall be answered by a response frame with the F-bit set to "1" at the earliest response opportunity.

No unsolicited F-bit = "1" is allowed. Such a frame shall be considered "improper" (see subclause 5.3.1). In ABM, the use of the P/F-bit with numbered information exchange is only allowed for checkpoint-recovery (see subclause 5.3.3).

#### 5.2.2 Unnumbered frames, U

#### 5.2.2.1 Set asynchronous balanced mode SABM (11100)

The SABM encoding is used as a command only. It is always used with the P-bit set to "1".

The SABM command is used either to initiate a link for numbered information transfer, i.e. to go from ADM to ABM, or to reset a link already established for numbered information transfer. With an SABM command, no information transfer is allowed.

When issuing an SABM, the RLP entity has set to zero its internal variables for sending and receiving numbered information. The other RLP entity, on receiving an SABM command, will either confirm it by setting to zero its internal variables for sending and receiving numbered information and then issuing an UA (unnumbered acknowledgement) response or reject it by sending a DM (disconnected mode) response. In the former case, both entities have entered ABM and numbered information transfer may commence. In the latter case, both entities are in ADM.

When an SABM command is issued, a loss of information may occur. Appropriate action is in the responsibility of the layers above.

#### 5.2.2.2 Unnumbered Acknowledge. UA (00110)

The UA encoding is used as a response only. It is used to positively acknowledge an SABM or DISC command. With the UA response, no information transfer is allowed.

#### 5.2.2.3 Disconnect, DISC (00010)

The DISC encoding is used as a command only. It is used to disestablish a link, previously established for numbered information transfer, i.e. to terminate ABM and go into ADM. With the DISC command, no information transfer is allowed.

The other RLP-entity shall answer with a UA response before actioning the DISC command. When a DISC command is actioned, loss of information may occur. It is the responsibility of the layers above, to provide for a "graceful" disconnect.

#### 5.2.2.4 Disconnected Mode, DM (11000)

The DM encoding is used as a response only. It is used by RLP entity to report that it is in ADM and, as an answer to SABM, that it is (possibly temporary) unable to action a mode setting command. With the DM response, no information transfer is allowed.

#### 5.2.2.5 Unnumbered Information, UI (00000)

The information field is to be interpreted as unnumbered information. Unnumbered Information (UI) frames can be sent in both ADM and ABM. There is no acknowledgement of receipt of UI-frames within RLP.

#### 5.2.2.6 Exchange Identification, XID (11101)

The information field is to be interpreted as exchange identification. This frame is used to negotiate and renegotiate parameters of RLP and layer 2 Relay function. XID frames can be sent in both ADM and ABM.

The negotiation procedure is one step i.e. one side will start the process by sending an XID command, offering a certain set of parameters from the applicable parameter repertoire (see table 1) the sending entity wants to negotiate proposing values within the allowed range. In return, the other side will send an XID response, either confirming these parameter values by returning the requested values, or offering higher or lower ones in their place (see table 1 for sense of negotiation), except when the indicated RLP version is a lower one where a limited set of those parameters presented in the XID command may be answered according to the negotiated version. In RLP versions higher than "0", any unrecognisable parameters will be ignored. Default values will apply to those parameters which are not commented upon by the responding side (see subclause 5.4 for default values). This normally will end the negotiation process. XID frames are always used with the P/F-bit set to "1".

#### Page 14 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

Without any prior XID exchange, default values will apply (see subclause 5.4). A negotiation of data compression parameters (see table 1) is only allowed in ADM.

In the case of a collision of XID commands, all XID commands shall be ignored. The MS shall restart the parameter negotiation on expiry of T1, while the Interworking Function shall do so on expiry of twice the value of T1. An unsuccessful XID exchange shall be repeated on expiry of T1. After N2 times of unsuccessful repetition, the link shall be disconnected.

In table 1 a list of parameters is given which constitute the parameter repertoire. In addition, the format of the XID information field is given.

Parameter Name	Туре	Length	Format (87654321)	Units	Sense of Negotiation	Valid in Versions
RLP version N°	1	1	bbbbbbbb <sup>*</sup>	./.	down	≥ 0
IWF to MS window size	2	1	00bbbbbb	./.	down	≥ 0
MS to IWF window size	3	1	00bbbbbb	./.	down	≥ 0
Acknowledgement timer(T1)	4	1	bbbbbbbb	10ms	up	≥ 0
Retransmission attempts (N2)	5	1	bbbbbbbb	./.	up	≥ 0
Reply delay (T2) **	6	1	bbbbbbbb	10ms	up	≥ 0
$\begin{array}{c} \text{Compression} & \text{P}_{\text{T}} \\ \text{P}_{0} \\ \text{P}_{1} \text{ low} \end{array}$	7	4	aaaa 00bb cccccccc	./. ./.	none see [15]	≥1
P <sub>1</sub> high P <sub>2</sub>			ccccccc ddddddd	./. ./.	down down	

#### Table 1: XID parameters

- \* NOTE 1: Characters "a", "b", "c" and "d" indicate a bit which is part of the parameter value in question. Parameters indicated by "a" are not negotiable.
- \*\* NOTE 2: In case of negotiation of this parameter it may be necessary to negotiate also the "Acknowledgement timer" (T1).

The type and length are encoded within one octet, the type field occupying bits 8 to 5 and the length field occupying bits 4 to 1; 1 resp. 5 being the least significant bit. The least significant bit shall always be transmitted first.

A parameter item consists of the type/length-octet followed by the value of that parameter, where the length-indicator gives the number of octets the value actually occupies. Such parameter items may be arranged in arbitrary order, with the exception of the RLP version number, which shall be sent first in RLP versions higher than "0". The parameter items must begin in the first octet of the XID-information field and follow on contiguously. The parameter list is delimited by parameter type zero.

## 5.2.2.7 Test, TEST (00111)

The information field of that frame is to be interpreted as test information. Test frames can be sent in both ADM and ABM. A test sequence is always initiated by sending a TEST command in one direction and completed by sending a TEST response in the other direction.

## 5.2.2.8 Null information, NULL (11110)

In ADM, null-frames shall be sent each time there is a send opportunity but no UI, TEST or XID frame is awaiting transmission.

In ABM, null-frames shall be sent in reset state if there is a send opportunity and no unnumbered frames are to be sent.

The information field is to be interpreted as null information i.e. the information field is not used and its contents may be arbitrary.

## 5.2.3 Supervisory frames, S, and numbered information transfer and supervisory frames combined, I+S

In ABM, there are cases where there is no user information pending transmission. In consequence, supervisory (S) frames alone must be conveyed. In such cases, the information field is to be interpreted as null information, i.e. the information field is not used and may be of arbitrary contents.

For reasons of optimization in the special situation of digital radio transmission, numbered information transfer frames carry also supervisory type information ("piggy-backing"). Numbered information can be exchanged only in ABM.

NOTE: The extent to which piggy-backing is used by the sending RLP entity is optional. An RLP entity receiving any of allowed piggy-backed formats, however, shall take the appropriate actions. Implementors should be aware that not using the full capability of piggy-backing could, in certain circumstances, result in a less than optimal performance.

#### 5.2.3.1 Send Sequence number, N(S)

The sequence number contains the number of the I frame. As far as N(S) is concerned, modulus 62 arithmetic is applied for frame numbering, thus allowing for a maximum window size of 61. On mutual agreement between the communicating parties, a smaller window size may be established. With the exception of SREJ conditions, information frames are transmitted in numerical order of their N(S). Normal information transfer is halted, when the number of outstanding, unacknowledged frames is equal to the currently established window size.

#### 5.2.3.2 Receive sequence number, N(R)

The N(R) field is used in ABM to designate the next information frame to be sent by the other RLP entity and to confirm that all frames up to and including N(R) - 1 have been received properly. As an exception to this, in the case of SREJ (selective reject), N(R) designates the information frame that is selectively rejected and thus requested for retransmission. In this case, no previously received frames are confirmed.

N(R) provides for a modulus of 62, thereby allowing for a maximum window size of 61, i.e. a maximum of 61 information frames may be outstanding at any time.

## 5.2.3.3 Receive ready, RR (00)

The RR encoding can be used either as command or response. In ABM, it is used by an RLP entity to confirm all information frames up to and including N(R)-1. In doing so, the RLP-station allows the other station to transmit up to k additional information frames, counting from N(R) onwards. The issue of an RR command/response clears any previous busy condition in that direction.

#### 5.2.3.4 Reject, REJ (01)

The REJ encoding can be used either as command or response. It is used by an RLP entity to indicate that in numbered information transfer one or more out-of sequence frames have been received. Frames up to and including N(R)-1 have been received correctly, frames N(R) and following are requested to be retransmitted. Following retransmission of those frames, further frames awaiting initial transmission may be sent. With respect to each direction of transmission, only one REJ condition may exist at any given time.

A REJ condition is cleared:

- on receipt of the frame numbered N(R);
- on time-out;
- or on reset (SABM).

An REJ shall be sent at the earliest opportunity. On time-out, REJ frames shall not be repeated. An RLP-entity receiving an REJ frame with the same N(R), which has already been the starting frame of a retransmission sequence due to P/F-bit checkpointing, shall inhibit the retransmission due to that particular REJ frame.

## Page 16 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

### 5.2.3.5 Receive not ready, RNR (10)

The RNR encoding can be used either as command or response. It is used by an RLP entity to indicate that it is temporarily not ready to receive numbered information frames. In that case, the RLP entity is said to be in the busy condition. All frames up to and including N(R)-1 shall be considered acknowledged. Subsequent frames, if any, shall not be considered confirmed. The acceptance status of those is a matter of further status exchange.

#### 5.2.3.6 Selective reject, SREJ (11)

The SREJ encoding can be used either as command or response. The SREJ command/response is used to request retransmission of a single frame, thus, under certain circumstances, providing for more efficient error recovery than by REJ. No acknowledgement of received I frames is indicated by an SREJ frame, thus allowing an RLP entity to transmit one or more SREJ frames with a different N(R) before earlier SREJ conditions have been cleared.

An SREJ condition shall be cleared:

- on receipt of an information frame with N(S) equal N(R) of the SREJ;
- on time out;
- on reset (SABM).

No SREJ shall be issued during a pending REJ condition. For each frame, only one SREJ condition may exist at any time.

SREJ frames shall be sent at the earliest possibility. On time-out, SREJ frames may be repeated.

NOTE: Sending SREJ commands/responses is not mandatory.

#### 5.3 Error Recovery

#### 5.3.1 Improper frames

Frames containing an FCS error or having a control field the contents of which is not implemented or inconsistent with those defined in this ETS are called improper frames. Improper frames shall be ignored, i.e. the receiving RLP station shall not make any use of their contents.

#### 5.3.2 N(S) sequence error

In numbered information transfer, any information frame with an N(S) out of the normal sequence shall lead to an N(S) sequence error condition, unless that frame is requested for retransmission by an SREJ, sent at an earlier time. There are three mechanisms to deal with N(S) sequence errors:

- REJ recovery;
- SREJ recovery;
- P/F-bit recovery (checkpointing);

the first two being the responsibility of the receiving station, the last being the responsibility of the sending station. There are no strict rules as to whether REJ or SREJ recovery shall be applied, however, if a station decides to initiate REJ or SREJ recovery, it shall do so at the earliest opportunity. The information part of out-of sequence frames shall be discarded, unless the receiving station intends to initiate SREJ recovery.

#### 5.3.3 Time-out and checkpointing

All frames requiring a response or acknowledgement shall be guarded by time-out (timer T1). In detail, those frames are:

- SABM;
- DISC;
- REJ;
- SREJ;
- numbered information frames (see note);
- any frame with the P-bit set to "1" in ABM, i.e. checkpointing.

#### 5.3.3.1 Treatment of errors during link establishment, link reset and link disconnect

An SABM, which is not answered by either UA or DM within the timer period, shall be repeated up to N2 times (Action on finally unsuccessful SABM is for further study, pending decisions on station management.)

A DISC, which is not answered by UA within the timer period, shall be repeated up to N2 times. If the DISC is finally unanswered, the RLP station will go into ADM in any case. For this reason, it is the responsibility of the management of any RLP entity to put the RLP entity into ADM, should there be an indication of a permanent outage, i.e. a loss of connectivity longer than N2 times the timer value.

NOTE: T1 started, or restarted if already running, on the transmission of every numbered information frame.

## Page 18 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

#### 5.3.3.2 Treatment of errors during numbered information transfer

The last frame of a sequence of numbered information frames shall also be guarded by time-out. If neither a positive acknowledgement nor a REJ is received, the RLP entity will start checkpoint recovery, i.e. the station will send a frame with the P-bit set to "1", requesting the latest status information from the other entity, indicated by the F-bit set to "1". In that case, status information is carried either by RR or RNR responses and all frames currently held by the responding RLP entity which are not delivered because of missing frames shall be discarded. A P-bit set to "1" shall only be sent with a Supervisory Frame.

Awaiting the latest status information from the other RLP entity, the sending entity does not react on REJ and SREJ frames received during this time. If such status information is received, retransmission from N(R) onwards will be performed if appropriate. However, no frame sequence starting with a given N(R) shall be retransmitted more than N2 times. If there is a frame sequence that cannot be transmitted successfully after N2 repetitions, the RLP link shall be reset or disconnected.

If no status information is received during the time-out period, this request will be repeated up to N2 times. If still there is no valid status reported back, the RLP link shall be reset or disconnected.

## 5.3.4 Contentious situations

Due to the asynchronous procedure, various contentious situations may arise. A contention of SABMs shall result into both entities be set into ABM or be reset. A contention of DISC's shall result into both entities be disconnected. A contention of SABM and DISC shall result into both entities be disconnected.

#### 5.4 List of system parameters

The system parameters are as follows:

Name	Range of values	Default value	Recommended value
Version N°	0 - 1	0	1
$k MS \Rightarrow IWF$	0 - 61	61	61
$k IWF \Rightarrow MS$	0 - 61	61	61
T1	> 380 ms > 440 ms > 600 ms	480 ms (fullrate on 12 kbit/s) 540 ms (fullrate on 6 kbit/s) 780 ms (halfrate)	480 ms (fullrate on12 kbit/s) 540 ms (fullrate on 6 kbit/s) 780 ms (halfrate)
T2		< 80 ms (fullrate on 12 kbit/s) < 80 ms (fullrate on 6 kbit/s) < 80 ms (halfrate)	< 80 ms (fullrate on 12 kbit/s) < 80 ms (fullrate on 6 kbit/s) < 80 ms (halfrate)
N2	> 0	6	6
PT	0	0	0
P <sub>0</sub>	0 - 3	0	3
P <sub>1</sub>	512 - 65 535	512	2 048
P <sub>2</sub>	6 - 250	6	20

#### Table 2: RLP parameter values

T2 < T1 (2 \* transmission delay)

#### 5.4.1 RLP Version N°

The current version of RLP is "1". "0" is the default value for the version N°. Version "1" is backwards-compatible with version "0". It is assumed that future versions of RLP will be backwards-compatible with former ones.

## 5.4.2 Maximum number of outstanding I frames k

The maximum number (k) of sequentially numbered I frames that may be outstanding (i.e. unacknowledged) at any given time is a system parameter which can never exceed 61. It shall be agreed for a period of time.

#### 5.4.3 Timer T1

The period of Timer T1 is regarded to start at the beginning of the transmission of the relevant frame.

The negotiation (or default) value is defined to be the earliest instant to enter recovery.

The period of Timer T1 at the end of which retransmission of a frame may be initiated according to the procedures described in 5.3 above, is a system parameter agreed for a period of time.

The proper operation of the procedure requires that Timer T1 be greater than the maximum time between transmission of frames (SABM, DM, DISC, I or supervisory commands) and the reception of the corresponding frame returned as a response to this frame (UA, DM or acknowledging frame). Therefore, the RLP entity should not delay the response or acknowledging frame returned to the above frame by more than a value T2. T2 is a system parameter, which is less than T1.

#### 5.4.4 Maximum number of retransmissions N2

The value of the maximum number of retransmissions N2 of a frame following the running out of Timer T1 is a system parameter agreed for a period of time.

#### 5.4.5 Data Compression Parameters

If the Layer 2 Relay function supports a data compression function and its use is desired the needed data compression parameters have to be negotiated. The parameter  $P_T$  is not negotiable. In case of V.42 bis the parameters  $P_0$ ,  $P_1$  and  $P_2$  have to be negotiated. The parameters are defined as follows:

- P<sub>T</sub>: Type of data compression
  - 0 V.42 bis
  - other values are reserved
- P<sub>0</sub>: V.42bis data compression request
  - 0 compress in neither direction
  - 1 compress in initiator-responder direction only
  - 2 compress in responder-initiator direction only
  - 3 compress in both directions
- P<sub>1</sub>: V.42bis number of possible codewords in the algorithm
- P<sub>2</sub>: V.42bis maximum encodable data string length

The initiator is the sender of XID command, the responder is the sender of XID response.

#### 5.5 Support for discontinuous transmission (DTX)

In both ADM and ABM, whenever the RLP entity has no numbered or unnumbered supervisory commands/responses and no information transfer frames pending transmission, the RLP entity shall indicate to the lower layer that the DTX function may be invoked.

NOTE: In case DTX is invoked, in ADM a NULL-frame will be sent, and in ABM an RR or RNR S-frame will be sent.

## Page 20 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

## 6 Service definitions

#### 6.1 Introduction

This chapter defines the service provided by the RLP-sublayer to the L2R-sublayer at the boundary between the RLP-sublayer and the L2R-sublayer.

The relationships between RLP-sublayer, L2R-sublayer and RLP-protocol are shown in figure 3.

#### Figure 3: Basic relationship between RLP and L2R

The RLP service is defined in terms of:

- the primitive actions and events of the service;
- the parameters associated with each primitive action and event;
- the inter-relationship between, and the valid sequence of, these actions and events.

#### 6.2 Conventions

For the description of the Data Link Service, the following conventions are used with time-sequence diagrams:

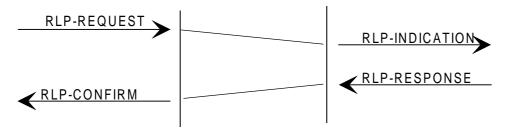

Figure 4: Confirmed service with acknowledgement

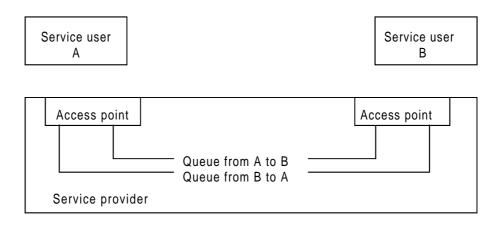

Figure 5: Unconfirmed service

In time-sequence diagrams, time moves from top to bottom. Arrows indicate the flow of information. Such flow of information may be subject to implicit flow-control. Skewed lines indicate a logical relationship between arrows. For clarity, the absence of such a relation may be marked by the symbol "~" (tilde).

#### 6.3 Queue model

Between the two endpoints of an RLP-connection, there exists a flow control function. As a means of specifying this flow control feature and its relationship with other capabilities of the RLP, the following queue model is provided.

#### Figure 6: Queue Model

The following objects may be placed in a queue by a service user:

- a) connect;
- b) connection-mode data (numbered information);
- c) reset;
- d) disconnect.

The following objects may be placed in a queue by a service provider:

- a) reset;
- b) synchronization mark;
- c) disconnect.

NOTE: Other possible objects (i.e. unnumbered information, identification, test) are irrelevant (-) to the queue model and for reasons of simplicity are not shown.

Following	Connect	Data	Reset	Sync Mark	Disconnect
Preceding					
Connect	NA			NA	DES
Data	NA		DES	NA	DES
Reset	NA		DES		DES
Synchronization Mark	NA		DES	NA	DES
Disconnect	NA	NA	NA	NA	DES

Legend:

- NA : Not applicable.
- -- : not destructive, not able to advance ahead of the preceding object.
- DES : Destructive to the preceding object.

## Annex A (informative): RLP SDL Diagrams

This annex describes a model implementation of an RLP entity for RLP version "0".

The description should help to clarify GSM 04.22, the RLP service and protocol definition.

However, it is not intended to restrict any implementation of an RLP entity in any way, on condition the implementation shows the correct behaviour at the RLP protocol level.

The model implementation consists of three processes. Process "SEND\_PDU" adds the CRC to a given PDU and hands it to the lower layer entity for transmission. Process "RECEIVE\_PDU" gets a received PDU block, checks the value of the CRC and the bits of the PDU header. If the CRC has the right value and if the header is syntactically correct, the receipt event is signalled to the "RLP\_KERNEL" process, which is the protocol handling automaton.

Each process is described as an extended finite state machine (using SDL-Diagrams).

Each state of the automaton is described by a (main-)state number and a corresponding (main-)state name. The state may further be distinguished by the value of other state variables. This scheme is used because not every state variable needs to be defined in every state. The states are defined in subclause A.1.

The RLP machine reacts on events, which may be classified as:

- lower layer interface events;
- upper layer interface events; and
- station management or internal events.

The events of the RLP-Kernel are described in subclause A.2.

## A.1 List of RLP entity states

#### A.1.1 (main) states

state number	state symbol	state name
0	S0	ADM and Detached
1	S1	ADM and Attached
2	S2	Pending Connect Request
3	S3	Pending Connect Indication
4	S4	ABM and Connection Established
5	S5	Disconnect Initiated
6	S6	Pending Reset Request
7	S7	Pending Reset Indication
8	S8	Permanent Error

#### A.1.2 state variables

The main states are further distinguished by the values of the state variables. However, not every state variable is used (evaluated/ defined) in every state.

First some constants need to be defined:

M = 62	number of different sequence numbers (modulus).
Nmin $= 0$	smallest sequence number.
Nmax = 61	largest sequence number (= M - 1)
N2 = 6	maximum number of retransmissions.

variable name	variable type and range	semantic
Ackn_FBit	(0, 1)	Value of the F-Bit used in the next acknowledging PDU
Ackn_State	(idle, send)	Ackn_State = send means, an acknowledging PDU (Supervisory or Data) has to be sent
С	(0, 1)	to store the C/R-Bit value of a received S- or I-frames
Data	char[25]	to store temporarily the information part (user data) of a received I-frame
DISC_Count	(0, 1,, N2)	to count the transmissions of DISC
DISC_PBit	(0, 1)	The value of the P-bit in the next DISC command PDU
DISC_State	(idle, send, wait)	if (DISC_State = send) the DISC command PDU has to be sent at the next possible opportunity if (DISC_State = wait) the RLP entity waits for the corresponding response
DM_FBit	(0, 1)	Value of the F-Bit used in the next DM response PDU
DM_State	(idle, send)	if (DM_State = send) the PDU DM has to be sent
DTX_SF	(N, RR, RNR)	to store the last Supervisory frame for DTX (only RR or RNR can be suppressed)
DTX_VR	(0, 1,, Nmax)	to store the last transmitted value of VR (used to decide the DTX condition)
F	(0, 1)	to store temporarily the F-bit of a received response PDU
NR	(0, 1,, Nmax)	to store temporarily the receive sequence number of a received S- or I-frame

## Page 28 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

NS	(0, 1,, Nmax)	to store temporarily the send sequence number of a received I-frame
Р	(0, 1)	to store temporarily the P-bit of a received command PDU
P_F	(0, 1)	to store temporarily the P- or F-bit of received command or response PDUs
Poll_Count	(0, 1,, N2)	to count the transmissions of poll requests
Poll_State	(idle, send, wait)	(Poll_State = send) means, a supervisory PDU with P-bit set to one has to be sent
		(Poll_State = wait) means, the RLP entity waits for the response with F-bit set to one
Poll_xchg	(idle, wait)	(Poll_xchg = idle) means, sending of a frame with P-bit set is allowed (Poll_xchg = wait) means, an acknowledgement of a previous P-bit is outstanding
R[M]	record array	Receiver slots (M slots, numbered 0 to M-1)
R[n].Data	char[25]	to store user information
R[n].State	(idle, rcvd, ackn, srej, wait)	<ul> <li>(R[n].State = rcvd) means, data has been received (with sequence number n)</li> <li>(R[n].State = ackn) means, data has been received and acknowledged</li> <li>(R[n].State = srej) means, the retransmission of data has to be requested using srej(n).</li> <li>(R[n].State = wait) means, the entity waits for the requested retransmitted data</li> </ul>
REJ_State	(idle, send, wait)	The REJ_State is send if and only if a REJ PDU has to be
		sent
returncode	Integer	sent used in procedures to report a result
returncode RRReady	Integer Boolean	
	-	used in procedures to report a result
RRReady	Boolean	used in procedures to report a result Remote Receiver Ready
RRReady SABM_Count	Boolean (0, 1,, N2)	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent
RRReady SABM_Count SABM_State	Boolean (0, 1,, N2) (idle, send, wait)	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent if (State = wait) the RLP entity waits for the UA response
RRReady SABM_Count SABM_State S[M]	Boolean (0, 1,, N2) (idle, send, wait) record array	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent if (State = wait) the RLP entity waits for the UA response Sender Slots (M slots, numbered 0 to M-1)
RRReady SABM_Count SABM_State S[M] S[n].Data	Boolean (0, 1,, N2) (idle, send, wait) record array char[25]	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent if (State = wait) the RLP entity waits for the UA response Sender Slots (M slots, numbered 0 to M-1) user information to be sent (S[n].State = send) means, data has to be sent
RRReady SABM_Count SABM_State S[M] S[n].Data S[n].State	Boolean (0, 1,, N2) (idle, send, wait) record array char[25] (idle, send, wait)	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent if (State = wait) the RLP entity waits for the UA response Sender Slots (M slots, numbered 0 to M-1) user information to be sent (S[n].State = send) means, data has to be sent (with sequence# n)
RRReady SABM_Count SABM_State S[M] S[n].Data S[n].State SF	Boolean (0, 1,, N2) (idle, send, wait) record array char[25] (idle, send, wait) (RR, RNR, REJ, SREJ)	used in procedures to report a result Remote Receiver Ready to count the transmissions of SABM if (State = send) the SABM PDU has to be sent if (State = wait) the RLP entity waits for the UA response Sender Slots (M slots, numbered 0 to M-1) user information to be sent (S[n].State = send) means, data has to be sent (with sequence# n) to store the last superv. System RLP - Overview

0422AF01.DRW 93-03-01

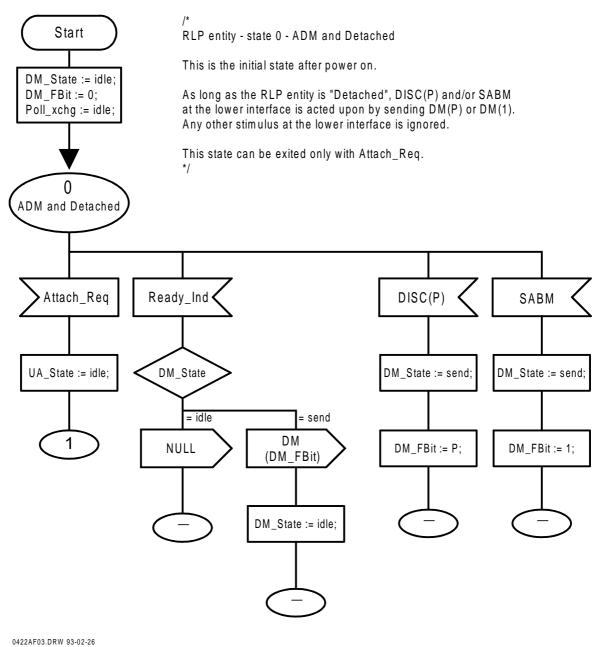

Figure 1

#### Page 32 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

0422AF02.DRW 93-05-25

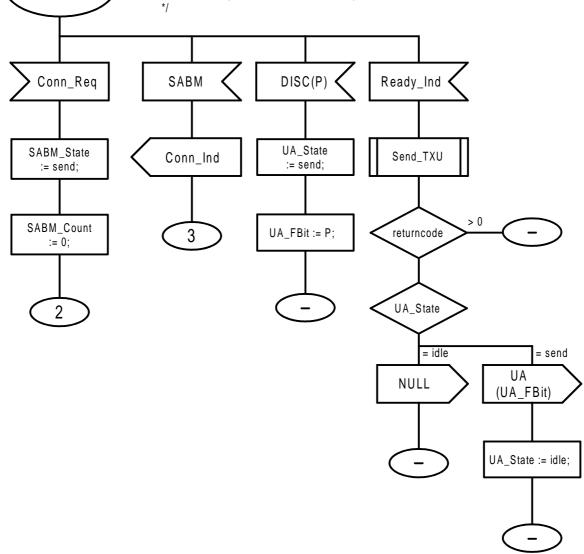

#### Page 34 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

ADM and Attached

RLP entity - state 1 - ADM and Attached

The RLP entity is ready to establish a connection, either by initiating the connection itself (Conn\_Req) or by responding to an incomming connection request (SABM).

Upon receiving a DISC PDU, the sending of the UA response is initiated.

0422AF04.DRW 93-02-25

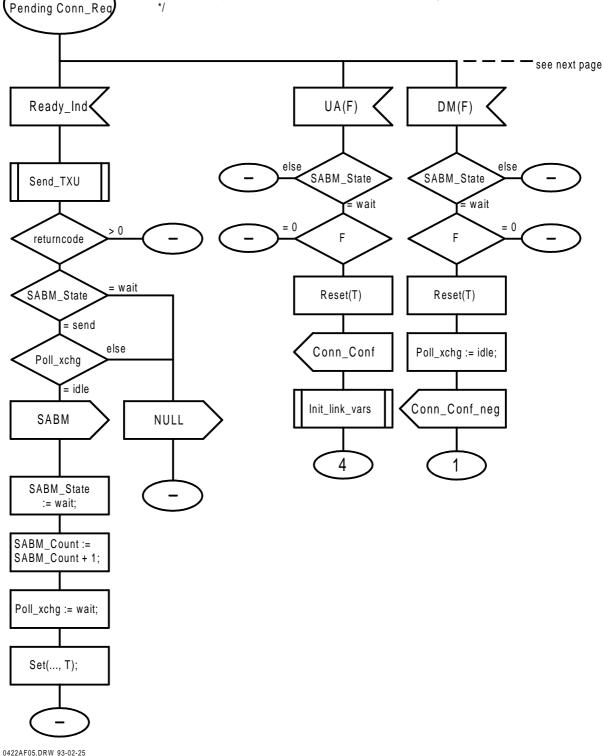

RLP entity - state 2 - Pending connect request

2

Send (up to N2 repetitions) SABM and wait for the corresponding UA with FBit = 1.

The (sub)state is controlled by the variable SABM\_State (values idle, send, wait) and SABM\_Count (values 0, 1, ..., N2).

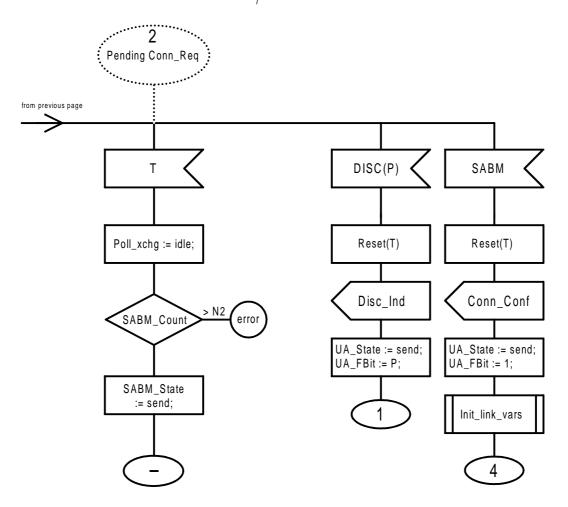

This state may be exited with a Disconnect Request (see figure 14).

#### Page 36 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

RLP entity - state 2 - Pending connect request

This figure allowes up to N2 repetitions of SABM and describes the disconnect and the SABM contention case.  $^{\ast/}$ 

0422AF06.DRW 93-02-25

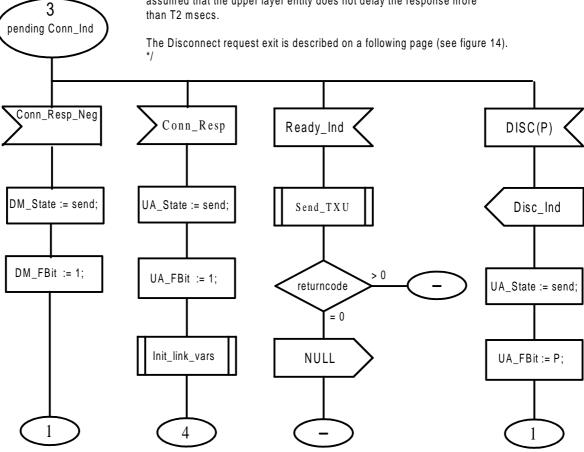

Figure 6

1

RLP entity - state 3 - pending Connect indication

After having received SABM, the RLP entity is waiting for the Connect response.

The upper layer entity may respond with Conn\_Resp or Disc\_Req. It is assumed that the upper layer entity does not delay the response more than T2 msecs.

0422AF07.DRW 94-09-15

Figure 7

#### Page 38 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

RLP entity - state 4 - Connection established

This is the data transfer state. The user entity may transmit data by fireing Data\_Requests. However, he is allowed to do so only if there are idle sender slots.

The data stored in the send slots will be transmitted at the next possible opportunity.

4 This state may be exited by a Disconnect Request (see figure 14). Connection \*/ established see next page Data\_Req DISC(P) Ready\_Ind (data) S[VD].State := send; Send\_TXU Reset(T); S[VD].Data := data; > 0 Reset(T\_RCVR) VD := VD + 1 returncode Reset all T\_RCVS's modulo M; Send\_Data Disc\_Ind UA\_State := send; UA\_FBit := P; 0422AF08.DRW 93-09-10 1

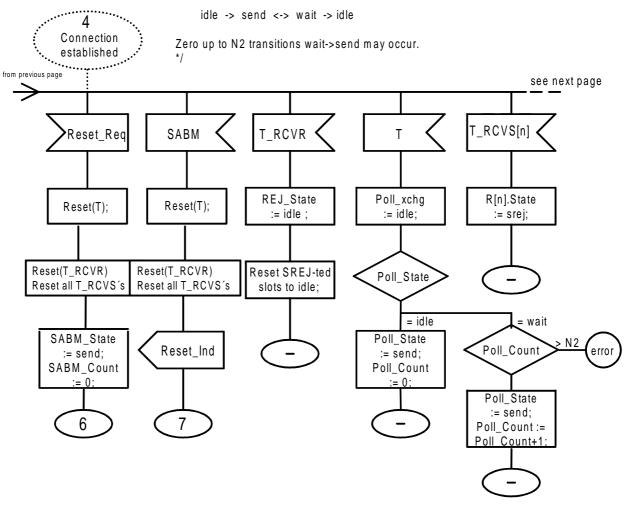

/

RLP entity - state 4 - Connection established

This dagram describes RESET and the Timeout-handling.

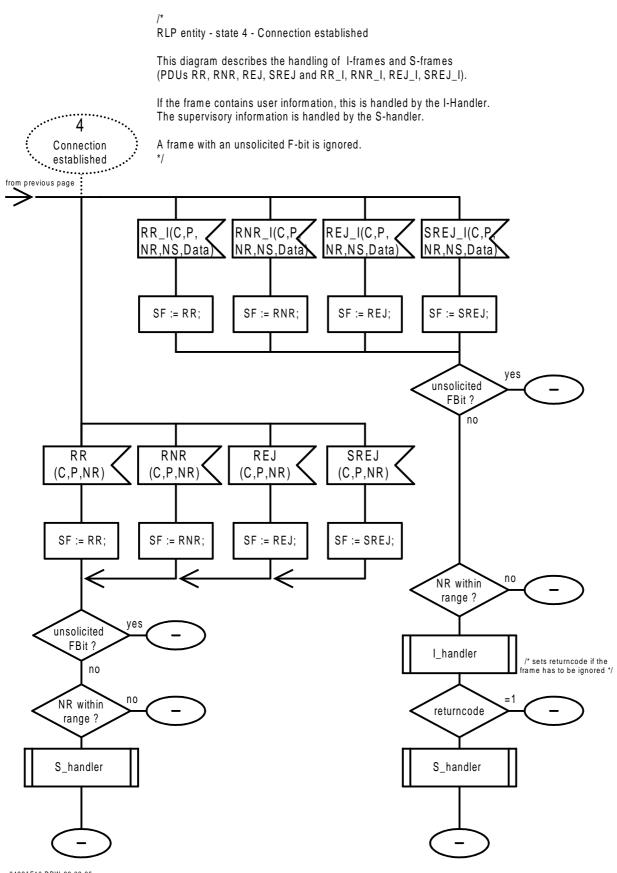

A timeout leads to error recovery by polling. This is controlled by the Poll\_State variable. The Poll\_State transitions are:

0422AF09.DRW 93-09-10

Figure 9

#### Page 42 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

\*/

6

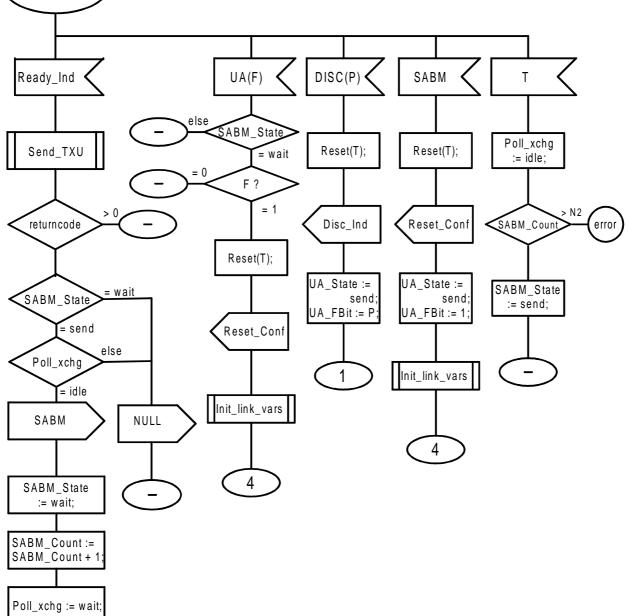

pending Reset\_Req

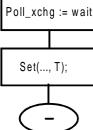

RLP entity - state 6 - pending Reset Request

Send (up to N2 repetitions) SABM and wait for the responding UA with FBit=1.

The substate is controlled by the variable SABM\_State (values idle, send, wait) and SABM\_Count (values 0..N2).

This state may be exited with a Disconnect Request (see figure 14).

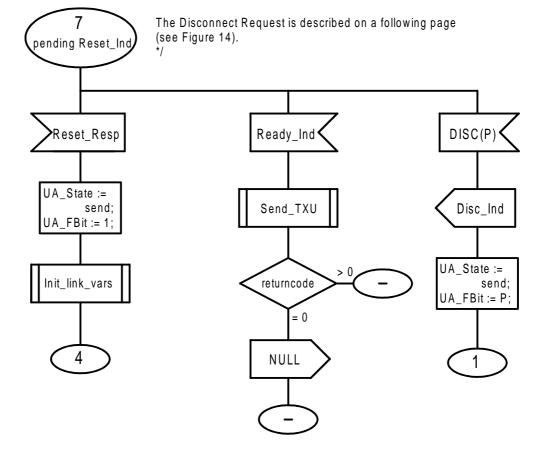

/\*

RLP entity - state 7 - pending Reset Indication

After having received SABM and having indicated Reset, the RLP entity is waiting for the Reset\_Response.

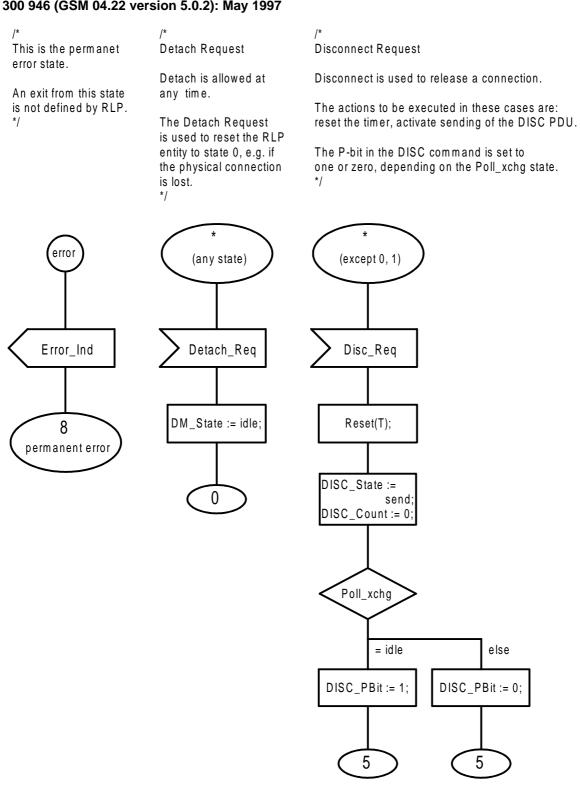

The upper layer entity may respond with Reset\_Resp or Disc\_Req. It is assumed, that the upper layer entity does not delay the response more than T2 msecs.

0422AF13.DRW 93-03-01

Figure 13

# Page 44 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

0422AF14.DRW 93-02-25

/\*

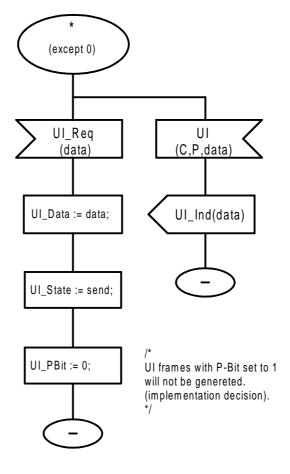

. UI handling (UI\_Req, UI)

Ul\_Requests are controlled using the state variable Ul\_State. The values (state transitions) are: idle -> send -> idle

It is assumed that the upper layer entity issues an UI\_Req only if the RLP entity's UI\_State is idle. The UI data is stored in the variable UI\_Data.

The UI\_PDU is generated at the next possible opportunity, i.e. after the higher priviled ged PDUs (TEST PDUs, XID PDUs, if any) have been transmitted.

\*/

0422AF15.DRW 93-02-26

Figure 15

#### Page 46 ETS 300 946 (GSM 04.22 version 5.0.2): May 1997

, XID handling (XID\_Req, XID)

XID requests are controlled using the state variable XID\_C\_State and XID\_R\_State. The state transitions being used are:

idle -> send -> wait -> idle. The XID data is stored in the variable XID\_C\_Data. (except 0) \*/ XID\_Req XID T\_ XID (C,P\_F,data (data) Poll\_xchg := idle; 0 XID\_R\_Stat С >= N2 XID Count erroi = 1 = idle = wait else < N2 else XID\_C\_State XID\_R\_State XID\_C\_State XID\_C\_State := send; := send; XID\_C\_State wait idle := send; else XID\_Ind XID\_Ind XID\_Count XID\_C\_Data  $P_F$ (data) (contention) := 0; := data; XID\_Count := 1 XID\_Count + 1; XID\_R\_State := Poll\_xchg Poll\_xchg XID\_C\_PBit wait local resp. := idle; := idle: := 1; XID\_C\_State XID\_R\_FBit  $Reset(T_XID)$ := P\_F; := idle; XID\_C\_Data := data; Xid Ind Set (data) ..(+),T\_XID XID\_C\_State := idle;

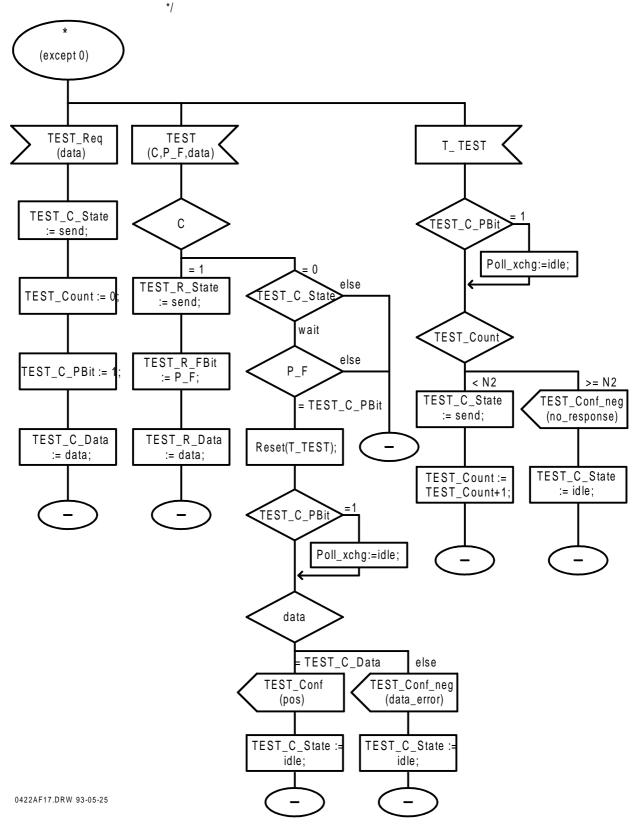

/\*

The action on a received XID command PDU depends on the state variable XID\_C\_State. In the contation case the XID Command is sent again after a certain delay, depending on the 'location' of the RLP entity.

The XID command/response PDU is sent at the earliest possible opportunity, next after a possible pending TEST PDU (see procedure SEND\_TXU) The value of the timer should be T1 ms in the Mobile Station, it should be twice this value in the Interworking Unit. This scheme is used to avoid repetinion of contentions.

Initialise link variables - This procedure is called if the link is established or the link is reset.

State = idle means: nothing to do, slot may be used (again). State = send means: send data at the next possible opportunity. State = wait means: wait for the acknowledgement \*/
