Intellectual Property Rights

Essential patents

IPRs essential or potentially essential to normative deliverables may have been declared to ETSI. The declarations pertaining to these essential IPRs, if any, are publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<https://ipr.etsi.org/>).

Pursuant to the ETSI Directives including the ETSI IPR Policy, no investigation regarding the essentiality of IPRs, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Trademarks

The present document may include trademarks and/or tradenames which are asserted and/or registered by their owners. ETSI claims no ownership of these except for any which are indicated as being the property of ETSI, and conveys no right to use or reproduce any trademark and/or tradename. Mention of those trademarks in the present document does not constitute an endorsement by ETSI of products, services or organizations associated with those trademarks.

DECT™, **PLUGTESTS™**, **UMTS™** and the ETSI logo are trademarks of ETSI registered for the benefit of its Members. **3GPP™** and **LTE™** are trademarks of ETSI registered for the benefit of its Members and of the 3GPP Organizational Partners. **oneM2M™** logo is a trademark of ETSI registered for the benefit of its Members and of the oneM2M Partners. **GSM®** and the GSM logo are trademarks registered and owned by the GSM Association.

Foreword

This Technical Report (TR) has been produced by ETSI Technical Committee Mobile Standards Group (MSG).

Modal verbs terminology

In the present document "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the [ETSI Drafting Rules](#) (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

Introduction

The present document presents the justification for the selection of the technical requirements within the Harmonised Standard for Base Stations under the guidance of ETSI EG 203 336 [i.2].

1 Scope

The present document describes why some parameters in the ETSI Guide [i.2] and 3GPP specifications [i.28] and [i.32] have not been included in the Base Station Harmonised Standards for E-UTRA [i.3], MSR [i.4], AAS [i.5] and NR [i.6].

3 Definition of terms, symbols and abbreviations

3.1 Terms

For the purposes of the present document, the following terms apply:

beam: main lobe of the radiation pattern of an *antenna array*

NOTE: For certain BS *antenna array*, there may be more than one *beam*.

beamwidth: *beam* which has a half-power contour that is essentially elliptical, the half-power beamwidths in the two pattern cuts that respectively contain the major and minor axis of the ellipse

BS class: classification of BS according to its intended use

NOTE: There are three *BS classes* in the present document: *wide area Base Station*, *medium range Base Station* and *local Area Base Station*.

carrier aggregation: aggregation of two or more component carriers in order to support wider *transmission bandwidths*

local area Base Station: Base Stations characterized by requirements derived from picocell scenarios with a BS to UE minimum coupling loss equal to 45 dB

medium range Base Station: Base Stations characterized by requirements derived from micro cell scenarios with a BS to UE minimum coupling loss equal to 53 dB

operating band: frequency range in which BS operates (paired or unpaired), that is defined with a specific set of technical requirements

TAB connector: *transceiver array boundary* connector

transceiver array boundary: conducted interface between the transceiver unit array and the composite antenna

transmission bandwidth: RF Bandwidth of an instantaneous transmission from a UE or BS, expressed in resource block units

NOTE: It is used as a frequency reference point for both transmitter and receiver requirements.

transmitter OFF period: time period during which the BS transmitter is not allowed to transmit

transmitter ON period: time period during which the BS transmitter is transmitting data and/or reference symbols

transmitter transient period: time period during which the transmitter is changing from the OFF period to the ON period or vice versa

wide area Base Station: Base Stations characterized by requirements derived from Macro Cell scenarios with a BS to UE minimum coupling loss equal to 70 dB

3.2 Symbols

For the purposes of the present document, the following symbols apply:

E_b/N_0 Energy per bit to noise power spectral density ratio

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

3GPP	3 rd Generation Partnership Project
AAS	Active Antenna System
ACLR	Adjacent Channel Leakage power Ratio
ACS	Adjacent Channel Selectivity
ADC	Analog-to-Digital Converter
AWGN	Average White Gaussian Noise
BS	Base Station
DDC	Digital Down Conversion
DL	Downlink
EG	ETSI Guide
EU	European Union
E-UTRA	Evolved UTRA
EVM	Error Vector Magnitude
FR1	Frequency Range 1
FR2	Frequency Range 2
ITU-R	Radiocommunication sector of the International Telecommunication Union
LO	Local Oscillator
MIMO	Multiple Input Multiple Output
MSG	Mobile Standards Group
MSR	Multi Standard Radio
NR	New Radio

NOTE: Also known as 5G.

OBUE	Operating Band Unwanted Emissions
RBW	Resolution Bandwidth
RE	Resource Element
RF	Radio Frequency
RIS	Radio Interface Specification
SNR	Signal to Noise Ratio

TAB	Transceiver Array Boundary
TDD	Time Division Duplex
TR	Technical Report
UE	User Equipment
UL	Uplink
UTRA	UMTS Terrestrial Radio Access

4 Technical parameters

4.1 General

The essential requirement in article 3.2 of Directive 2014/53/EU [i.1] states:

"Radio equipment shall be so constructed that it both effectively uses and supports the efficient use of radio spectrum in order to avoid harmful interference."

When deciding which transmitter parameters have been included, justification for the requirements in relation to transmitters is given by recital 10 of the Directive, which states:

"...when the transmitter is properly installed, maintained and used for its intended purpose it generates radio waves emissions that do not create harmful interference, while unwanted radio waves emissions generated by the transmitter (e.g. in adjacent channels) with a potential negative impact on the goals of radio spectrum policy should be limited to such a level that, according to the state of the art, harmful interference is avoided."

The intention of the essential requirements in article 3.2 of Directive 2014/53/EU [i.1] in relation to a receiver is explained in recitals 10 and 11 of the Directive, which state:

"...in the case of a receiver, it has a level of performance that allows it to operate as intended and protects it against the risk of harmful interference, in particular from shared or adjacent channels, and, in so doing, supports improvements in the efficient use of shared or adjacent channels. Although receivers do not themselves cause harmful interference, reception capabilities are an increasingly important factor in ensuring the efficient use of radio spectrum by way of an increased resilience of receivers against harmful interference and unwanted signals on the basis of the relevant essential requirements of Union harmonisation legislation."

As such, in the following, efficient use of spectrum for the receiver is then considered in the scope of increasing resilience of receivers against harmful interference and unwanted signals, and not maximizing data throughput performance.

4.2 ETSI Guide parameters

4.2.1 Introduction

The parameters under article 3.2 of Directive 2014/53/EU [i.1] listed in ETSI EG 203 336 [i.2] are analysed in the following clauses.

4.2.2 Transmitter power limits

Transmitter power limits for BS are not considered in the Harmonised Standards as most spectrum decisions [i.8] to [i.27] have no obligatory limit on in-band power, where in-band power limits apply in the spectrum decision these of course apply. In addition, power limits are defined in national Radio Interface Specifications (RIS) and also in individual or general licence authorizations, and these apply.

As transmitter power accuracy is specified and measured, no separate maximum transmitter power requirement or test is needed.

4.2.3 Transmitter frequency stability

The frequency stability could impact the radio system transmitter's ability to occupy a specified bandwidth at its own assigned portion of frequency (channel bandwidth), without leaking into adjacent channels. The frequency error requirement defined in 3GPP [i.28] to [i.32] is on the order of 0,05 to 0,1 ppm (0,05 ppm corresponds to 100 Hz at 2 GHz carrier signal). This accuracy is related to the cell search and initial access and is not relevant for harmful interference or efficient use of spectrum, since it is several orders of magnitude stricter than what would be needed to ensure that the transmitter occupies its assigned channel without leaking into adjacent channels. The already included ACLR and OBUE requirements ensure that the transmitter's power does not adversely leak into adjacent channels. For this reason, a requirement on transmitter frequency stability is not considered for inclusion in the Harmonised Standards.

4.2.4 Transmitter intermodulation attenuation

The FR1 BS Harmonised Standards include requirements for transmitter intermodulation for both conducted and radiated requirements.

For FR2 radiated requirements, there is no transmitter intermodulation requirement as high isolation path loss due to the high mm-wave frequencies in the co-location scenarios mean the signal coupled between co-located antennas is so low that a transmitter capable of meeting the other RF linearity requirements will easily meet the emissions requirements under such a low level reverse interferer, as such no transmitter intermodulation requirement is necessary.

4.2.5 Transmitter time domain characteristics

The Harmonised Standard does not include transmitter time domain characteristics; however, transmit ON/OFF power is specified in 3GPP, e.g. [i.34] and [i.35].

The UTRA/E-UTRA/NR system uses fixed channels and does not use frequency hopping, so time domain alignment cannot interfere with other channels.

For TDD operation, a power mask is defined for the BS output power, defining the OFF power level during the uplink subframes and the maximum time for the transmitter transient period between the transmitter ON and OFF states. The transmit OFF power is the power measured over the transmission bandwidth when the transmitter is OFF. The transmitter transient period is the time period during which the transmitter is changing from the OFF period to the ON period or vice versa.

Both requirements would protect reception phase from transmission phases, enabling TDD operations inside the Base Station channel bandwidth. For this reason, transmitter ON/OFF power requirement is not relevant for harmful interference or efficient use of spectrum.

4.2.6 Transmitter transients

The Harmonised Standard does not include transmitter transient's technical requirements, and it is also not included in the 3GPP requirements.

For BS operating in TDD mode, the time required to switch between UL and DL or transmit and receive is specified in 3GPP [i.28] to [i.32] as transmit transient period and is in the order of 10 microseconds. This switching speed if it were to generate transients they would be in the order of 100's of kHz. In BS Harmonised Standards, the potential transients at these offsets do not affect the system and can be treated as in band and are covered by the operating band emissions requirements.

4.2.7 Receiver co-channel rejection

All receiver requirements are predicated on an assumption of the ability to maintain a certain quality metric at a minimum E_b/N_0 value. The ability of the receiver to demodulate in the presence of on-channel noise is hence tested in all receiver requirements, sensitivity ACS, blocking, etc. Any in-band interference adds to the N_0 power value, and as such co-channel interference does not need to be specifically tested.

4.2.8 Receiver selectivity

4.2.8.1 Receiver spurious response rejection

Receiver spurious response rejection is a measure of the receiver's capability to receive a wanted signal without exceeding a given degradation due to the presence of an unwanted signal at any frequency at which a response is obtained.

The BS Harmonised Standards out of band blocking requirements cover all out of band frequencies including any spurious response.

4.2.9 Other receiver effects

4.2.9.1 Receiver dynamic range

In the UTRA/E-UTRA/NR systems, the UL power levels from the UE are controlled, and as such, it is not possible to receive a wanted signal that is high enough to produce any overloading effects. Linearity and high input signal levels are characterized by un-wanted in-band input signals in the in-band blocking requirement.

Receiver dynamic range is defined as the range of the wanted input signal level over which a receiver functions at a specified performance level. The lower end of this range is normally the sensitivity of the receiver. The upper end of a receiver's dynamic range determines how strong a received signal can be before producing degradation due to overloading.

Many receivers are deployed in a manner that results in a situation where it is impossible to receive a wanted signal that is high enough to produce any overloading effect. In these cases, ETSI Technical Bodies may decide not to specify receiver dynamic range.

The dynamic range of a receiver may be specified in an Harmonised Standard as a "stand-alone" requirement where the operational situation provides minimum/maximum operational distances from a common transmitter.

In all other cases, it is considered that the dynamic range of the receiver is implicitly covered in an Harmonised Standard where interference characteristics are specified in terms of selectivity requirements, including blocking.

4.2.9.2 Reciprocal mixing

Reciprocal mixing occurs when noise sidebands of the Local Oscillator (LO) mix with interfering signals at distances from the wanted signal comparable to the LO offset range where phase noise is higher than the thermal noise (i.e. from few hundreds Hz to few MHz) converting unwanted noise at the frequency of the receiver which may result in "desensitization" of the receiver (see note 1), additional to that produced by the interference itself. In direct Digital Down Conversion receivers (DDC), a similar effect occurs caused by the phase jitter (see note 2) of the clock associated with the ADC.

It is considered that the reciprocal mixing effects are implicitly covered in the Harmonised Standards where comprehensive interference characteristics are specified in terms of selectivity and/or blocking requirements, thus removing the need for this parameter to be included in the Harmonised Standards as the effects of receiver selectivity and reciprocal mixing cannot be separated.

NOTE 1: In communications receivers intended for use in interference-limited rather than noise-limited environments, degradation due to reciprocal mixing may occur before degradation due to non-linearity. As a result, reciprocal mixing may be the dominant effect in those receivers' performance.

NOTE 2: The term "jitter" is often used in digital systems whereas the term "phase noise" is used in traditional radio systems; however, the two terms refer to the variation in phase of a signal and are, therefore, essentially the same phenomenon.

In the BS Harmonised Standard, the effects of reciprocal mixing are covered by the ACS and the in-band blocking requirements.

4.3 3GPP parameters

4.3.1 Output power dynamics

The Harmonised Standard does not include transmitter output power dynamics.

The output power dynamics requirements in 3GPP interpretation are defined to ensure that the BS transmitter has an output power dynamic range to handle the modulation schemes and channel bandwidths that are part of the downlink. Resource Element (RE) power control dynamic range defines the range needed for power control per RE relative to the average RE power at max BS output power, defined for each of the downlink modulation schemes. The total power dynamic range is defined for each channel bandwidth to enable dynamics from 1 RE up to the maximum number of RE for that channel bandwidth. All requirements relate to the possibility for scheduling in the downlink, which creates varying output power levels, while the maximum power level is defined by the already included Base Station maximum output power requirement. For this reason, the output power dynamic range requirements are not relevant for harmful interference or efficient use of spectrum.

4.3.2 Transmit signal quality

Modulation Quality/Error Vector Magnitude (EVM)

EVM is a measure of the difference between the ideal modulation symbols and the measured symbols after equalization at the receiver. This maximum allowed transmitter error is set to achieve enough SNR at the receiver for the chosen modulation scheme. Since it is not related to carrier leakage or unwanted emissions from the transmitter, it is not relevant for harmful interference or efficient use of spectrum.

Time Alignment Error

Several features require the Base Station to transmit from two or more antennas, such as transmitter diversity and MIMO. For carrier aggregation, the carriers may also be transmitted from different antennas. In order for the UE to properly receive the signals from multiple antennas, the timing relation between any two transmitter branches is specified in terms of a maximum time alignment error between transmitter branches. For this reason, Time Alignment Error requirement is not relevant for harmful interference or efficient use of spectrum.

Frequency error is also in the transmit signal quality clause but has been discussed in clause 4.2.3 on the frequency stability.

4.3.3 Occupied bandwidth

The occupied bandwidth is the width of a frequency band such that, below the lower and above the upper frequency limits, the mean powers emitted are each equal to a specified percentage (0,5 %) of the total mean transmitted power (see also Recommendation ITU-R SM.328 [i.33]).

The occupied bandwidth, defined in the Radio Regulations of the International Telecommunication Union ITU [i.36], is a useful concept for specifying the spectral properties of a given emission in the simplest possible manner. The test purpose is to verify that the emission of the BS does not occupy an excessive bandwidth for the service to be provided and is, therefore, not likely to create interference to other users of the spectrum beyond undue limits.

The method is to measure the spectrum emission of the transmitted signal using at least the number of measurement points and across a specified span. The selected Resolution Bandwidth (RBW) filter of the analyser is 30 kHz or less.

While the occupied bandwidth is related to unwanted emissions outside the assigned channel, it is not a precise measure, since it does not identify where the unwanted emissions would fall in the out-of-band domain, where the already included requirements on Operating band unwanted emissions and ACLR are securing a low level of interference to other systems. For this reason, the occupied bandwidth is not relevant for harmful interference or efficient use of spectrum.

4.3.4 In channel selectivity

In channel selectivity is a requirement defined in the 3GPP specifications for the BS [i.28] to [i.32].

The in-channel selectivity is defined as a measure of the receiver's ability to receive a wanted signal at its assigned resource block locations in the presence of an interfering signal received at a larger power spectral density, at which a throughput requirement is fulfilled. The intention of this requirement is to address in-band adjacent resource block selectivity, i.e. the reception of simultaneous user signals at greatly different power spectral density levels. As mentioned in the naming of this requirement, In-Channel selectivity would not improve performance against unwanted signals or harmful interference from adjacent channels. For this reason, In-Channel selectivity requirement is not relevant for harmful interference or efficient use of spectrum.

4.3.5 Dynamic range

Dynamic range is a requirement defined in the 3GPP specifications for the BS [i.28] to [i.32].

The term "Dynamic Range" as defined by 3GPP requires additional clarification. Dynamic range of a receiver is usually defined as the input signal power range at the antenna input port over which the data error rate does not exceed a specific value. The lower end of the dynamic range is close to the receiver sensitivity power level, while the maximum input power level at which the error data rate remains below the target specification determines the upper end of the dynamic range. The specification of the "Dynamic Range" as introduced in e.g. [i.32] describes a completely different test case. The dynamic range is specified as a measure of the capability of the receiver to receive a wanted signal in the presence of an interfering signal inside the received channel bandwidth. In this condition, a throughput requirement is met for a specified reference measurement channel. The interfering signal for the dynamic range requirement is an Average White Gaussian Noise (AWGN) signal. The target throughput is specified to be ≥ 95 % for the given conditions. This requirement is relevant for BS due to the multiple transmissions that can exist in the receiver channel; however, this is not very relevant when it comes to efficient use of spectrum or harmful interference. Interference level in a cellular network is a design parameter controlled by the network operator. The Dynamic range requirement as defined in 3GPP is therefore not needed in the Harmonised Standard.
