## Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://www.etsi.org/ipr>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

---

## Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Broadband Radio Access Networks (BRAN).

The present document gives guidelines for network management of HIPERLAN Type 2 (HIPERLAN/2) devices and defines a HIPERLAN/2 SNMP MIB.

---

## Introduction

The present document is organized in the following way:

- Clause 4 describes some general preconditions for the MIB definition;
- Clause 5 describes the H/2 SNMP MIB;
- Annexes A, B, C, and D contain the MIB definitions (ASN.1).

TR 101 683 [1] contains an overall description of the HIPERLAN/2 system. The Physical (PHY) layer is described in [2], the Data Link Control (DLC) layer is described in [3], the Radio Link Control (RLC) sublayer is described in [4], and the Convergence (CL) layers for Ethernet and ATM UNI are described in [5], [6], [7], and [8].

---

## 1 Scope

The purpose of the present document is to provide a common view of HIPERLAN Type 2 (H/2) devices from different vendors for basic network monitoring and network control. This is achieved by defining a H/2 SNMP MIB to optionally be included in H/2 devices. For network monitoring basic performance and fault monitoring is covered. A basic set of configuration parameters is defined for network control.

Systems management like device setup, software upgrade and also the manager side for network management is out of the scope of the present document.

---

## 2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, subsequent revisions do apply.
- A non-specific reference to an ETS shall also be taken to refer to later versions published as an EN with the same number.

### 3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

AP	Access Point
ASN.1	Abstract Syntax Notation One
CL	Convergence Layer
H/2	HIPERLAN Type 2
MIB	Management Information Base
MT	Mobile Terminal
OID	Object Identifier
PC	Personal Computer
SMI	Structure of Management Information
SNMP	Simple Network Management Protocol
TS	Technical Specification

## 4 H/2 Network Management

This clause gives the preconditions for clause 5 where the H/2 MIB, the SNMP framework etc. are described.

The purpose of defining a MIB and related principles is to provide a common view to the human network manager of H/2 devices from different vendors. Basic performance and fault monitoring is covered for network monitoring. A basic set of configuration parameters is defined for network control.

Systems management like device setup and software upgrade and also the manager side for network management are considered to be vendor specific and are not described in the present document. Vendor specific additions to the H/2 MIB can be placed in vendor specific MIBs.

It is assumed that each H/2 device with SNMP support besides the H/2 MIB contains at least parts of the Internet standard MIB, MIB-II.

### 4.1 Basic Principles

- SNMP network management requires an IP core network. SNMP often implies a corporate (business) environment.
- Centralized mode (see [3]) is covered. In the future direct mode (see [3]) may be covered.
- The H/2 SNMP MIB is defined in the present document for the AP. In the future it may be adapted to any managed H/2 device by excluding or adding groups and single objects.
- SMIv2 (Structure of Management Information) is used for the definition of the H/2 MIB. An easy transformation to SMIv1 (and SNMPv1) is provided so a SNMPv1 manager can be used. For more information on SMI see 5.1.
- SNMPv3 is recommended for security reasons, but SNMPv3 is not mandatory. For more information on security see 5.1 and 5.2.

### 4.2 Management of MT

In a corporate network the MTs (PCs) are normally not monitored via SNMP because of the large number of devices. In a H/2 environment the mobility of the MTs adds extra complexity.

The AP's view of the associated MTs is included in the H/2 MIB located in the AP. This can be the start for trouble shooting MT related problems.

### 4.3 Mapping of the H/2 Radio Interface on the Interface Table of MIB-II (informative)

The interface table (ifTable) of the standard Internet MIB MIB-II provides information for understanding of how the network interfaces of a device are performing. All types of managed network devices support the interface table of MIB-II. An AP normally supports interface entries for the core network interface and the H/2 radio interface.

Characteristics of the H/2 radio interface are mapped on an interface entry of the interface table of MIB-II. This makes the H/2 device look like any network device to the network manager.

Different methods can be used when mapping the H/2 radio interface on the ifTable of MIB-II. The mapping can be done according to RFC 1213 [25] or via an extended ifTable as described in RFC 2233 [26]. If the extended ifTable is used it is possible to define interface entries for supported CLs besides the H/2 interface entry. The order of the interfaces can be defined e.g. indicating that a CL interface is on top of the H/2 interface.

Table 1 proposes a mapping for an AP according to RFC 1213 [25]. Some comments:

- The layer described in ifTable is DLC. Upper layer is CL. The interface to and from the upper layer is DLC-U-SAP, see DLC [3]. Lower layer is PHY [2].

- Packet in RFC 1213 [25] means here a UDCH, UMCH, or UBCH message (see [3]).
- From ifSpeed, ifInOctets, and ifOutOctets it should be possible to calculate the utilization of the H/2 interface. Just counting the data octets does not tell the utilization because of the link adaptation. Example: In a cell, there is a single MT near the AP constantly using a data rate of 5Mbit/s. The MT is moved to the cell border still using a data rate of 5 Mbit/s. The utilization of the H/2 interface of the AP is now perhaps 5 times larger than before. This is the reason why ifInOctets and ifOutOctets in Table 1 are provided as normalized octets. A normalized octet represents a constant portion of the MAC frame, see clause 4.4.

NOTE: ifInOctets and ifOutOctets is not showing the data traffic through the AP. The traffic can be estimated from other attributes e.g. ifInUcastPkts and ifOutUcastPkts (see Table 1).

**Table 1: Mapping of a H/2 Interface Entry**

Object	Syntax / Access	Description (RFC 1213 [25])	H/2 Implementation
ifDescr	DisplayString read-only	Information about the interface including the name of the manufacturer, the product name and the version of the hardware interface.	According to description.
ifType	INTEGER read-only	The type of interface, distinguished according to the physical/link protocol(s) immediately "below" the network layer in the protocol stack.	"hiperlan2(183)" or "other(1)"
ifMtu	INTEGER read-only	The size of the largest datagram, which can be sent/received on the interface, specified in octets.	Not very relevant but in order not to fool a smart management application set equal to smallest MTU size of supported CLs e.g. 1 518 in case of Ethernet.
ifSpeed	Gauge read-only	An estimate of the interface's current bandwidth in bits per second. For interfaces which do not vary in bandwidth or for those where no accurate estimation can be made, this object should contain the nominal bandwidth.	A fix max bit rate supported by the AP. ifSpeed should be set so it is not exceeded but not too high either so the real speed always is far from ifSpeed. See also clause 4.4.
ifPhysAddress	PhysAddress read-only	The interface's address at the protocol layer immediately "below" the network layer in the protocol stack. For interfaces which do not have such an address (e.g., a serial line), this object should contain an octet string of zero length.	According to description.
ifAdminStatus	INTEGER read-write	The desired state of the interface. The testing state indicates that no operational packets can be passed	According to description.
ifOperStatus	INTEGER read-only	The current operational state of the interface. The testing(3) state indicates that no operational packets can be passed	According to description.
ifLastChange	TimeTicks read-only	The value of sysUpTime (time since start) at the time the interface entered its current operational state.	According to description.
ifInOctets	Counter read-only	The total number of octets received on the interface (i.e. from media), including framing characters.	Provided as "normalized octets" showing how occupied the medium is. See "Definition of Normalized Octet" below.
ifOutOctets	Counter read-only	The total number of octets transmitted out of the interface (i.e. to media), including framing characters.	Provided as "normalized octets" showing how occupied the medium is. See clause 4.4.
ifInUcastPkts	Counter read-only	The number of subnetwork-unicast packets delivered to a higher-layer protocol	Number of DLC-SDUs containing unicast information delivered from DLC to CL over DLC-U-SAP. Multicast as n times unicast is counted as unicast. I.e. the number of received UDCH messages DLC is handing over to CL.
ifOutUcastPkts	Counter read-only	The total number of packets that higher-level protocols requested be transmitted to a subnetwork-unicast address, including those that were discarded or not sent.	Number of DLC-SDUs containing unicast information delivered from CL to DLC over DLC-U-SAP. Multicast as n times unicast is counted as unicast. I.e. the number of UDCH messages DLC is requested to transmit.
ifInNUcastPkts	Counter read-only	The number of non-unicast (i.e., subnetwork-broadcast or subnetwork-multicast) packets delivered to a higher-layer protocol.	0. UMCH or UBCH is only for downlink.
ifOutNUcastPkts	Counter read-only	The total number of packets that higher-level protocols requested be transmitted to a non-unicast (i.e., a subnetwork-	Number of DLC-SDUs containing multicast or broadcast information delivered from CL to DLC over DLC-U-SAP. In case of

Object	Syntax / Access	Description (RFC 1213 [25])	H/2 Implementation
		broadcast or subnetwork-multicast) address, including those that were discarded or not sent.	repetition mode [3] the UBCH message is only counted once. I.e. the number of UMCH and UBCH messages DLC is requested to transmit.
ifInDiscards	Counter read-only	The number of inbound packets which were chosen to be discarded even though no errors had been detected to prevent their being deliverable to a higher-layer protocol. One possible reason for discarding such a packet could be to free up buffer space.	According to description. Discards in CL are counted too when relevant.
ifOutDiscards	Counter read-only	The number of outbound packets which were chosen to be discarded even though no errors had been detected to prevent their being transmitted. One possible reason for discarding such a packet could be to free up buffer space.	According to description. Discards in CL are counted too when relevant.
ifInErrors	Counter read-only	The number of inbound packets that contained errors preventing them from being deliverable to a higher-layer protocol.	Number of discarded uplink UDCH messages. Could not be correctly received from the MT in spite of retries (bit errors or any other error but not resource problems).
ifOutErrors	Counter read-only	The number of outbound packets that could not be transmitted because of errors	Number of discarded UDCH, UMCH, and UBCH messages. Could not be correctly transmitted by the AP in spite of retries (bit errors or any other error but not resource problems).
ifInUnknownProtos	Counter read-only	The number of packets received via the interface which were discarded because of an unknown or unsupported protocol	0
ifOutQLen	Gauge read-only	The length of the output packet queue (in packets).	Not supported.
ifSpecific	OBJECT IDENTIFIER read-only	A reference to MIB definitions specific to the particular media being used to realize the interface.	{0 0}. Not useful.

## 4.4 Definition of Normalized Octet (informative)

A normalized octet is a logical concept intended to represent a constant portion of the MAC frame. Normalized octets are used when implementing support for ifInOctets and ifOutOctets (see Table 1) in the H/2 device. A definition of a normalized octet needs the definition of a normalized bit. The time interval of a normalized bit is constant while the time interval of a data bit is variable depending on the link adaptation. The normalization means that the number of normalized bits per OFDM symbol is calculated so that when the MAC frame is full ifSpeed is reached. A simplified example is shown below:

Example: A vendor has estimated the maximum data rate under best conditions (ifSpeed) to 25 Mbit/s for an AP of a certain type. The time interval of an OFDM symbol is 4 µs. This corresponds to  $0,25 \times 10^6$  OFDM symbols/s. The normalized number of bits per OFDM symbol (n) can now be calculated:

$$n \times 0,25 \times 10^6 = 25 \times 10^6 \Rightarrow n = 100 \text{ normalized bits per OFDM symbol.}$$

One way to implement the support for e.g. ifOutOctets is to count the number of downlink OFDM symbols in each MAC frame, multiply with n/8, and add to ifOutOctets.

## 4.5 Agent Implementation

The implementation of the H/2 MIB and the H/2 mapping on the interface table of MIB-II are done via "best effort" in a vendor device. Any deviations for an agent implementation shall be documented in an agent capability specification (RFC 2580 [16]).

NOTE: The implementation of the H/2 MIB shall be done so the MIB attributes reflect the real values the attributes represent. An example of a bad implementation is a counter that is not stepped frequently not following the real value it represents. The update of the attributes should be done at least once a second.

## 5 H/2 SNMP MIB

### 5.1 The SNMP Network Management Framework

Managed objects are accessed via a virtual information store, called Management Information Base (MIB). Objects in the MIB are defined according to a SMI (Structure of Management Information) definition.

The SNMP Management Framework is defined in a set of RFCs. Framework components are:

- 1) An overall architecture (RFC 2571 [10]).
- 2) The SMI, i.e. mechanisms for describing and naming management objects and events. The first version, SMIv1, is described in STD 16, RFC 1155 [11], STD 16, RFC 1212 [12] and RFC 1215 [13]. The second version, called SMIv2, is described in STD 58, RFC 2578 [14], STD 58, RFC 2579 [15] and STD 58, RFC 2580 [16].
- 3) Message protocols for transferring management information. The first version, SNMPv1, is described in STD 15 [17], RFC 1157 [16]. The second version, SNMPv2c (not an Internet standards track protocol) is described in RFC 1901 [18] and RFC 1906 [19]. The third version, SNMPv3, is described in RFC 1906 [19], RFC 2572 [20] and RFC 2574 [21].
- 4) Protocol operations for accessing management information. The first set of protocol operations and associated PDU formats are described in STD 15 [17], RFC 1157 [16]. A second set of protocol operations and associated PDU formats are described in RFC 1905 [22].
- 5) Fundamental applications (RFC 2573 [23]) and the view-based access control mechanism (RFC 2575 [24]).

The present document specifies a MIB module that is compliant to SMIv2. A MIB conforming to SMIv1 can be produced through appropriate translations. The translated MIB shall be semantically equivalent, except where objects or events are omitted because no translation is possible (use of Counter64). Some machine readable information in SMIv2 will be converted into textual descriptions in SMIv1 during the translation process. This is not considered to change the semantics of the MIB.

### 5.2 Security Considerations

The H/2 MIB contains some read-only objects and some read-write objects. Unauthorized access to readable objects can be considered to be rather harmless. Unauthorized access to writable objects can be harmful, e.g. disturbing the operations of a H/2 device.

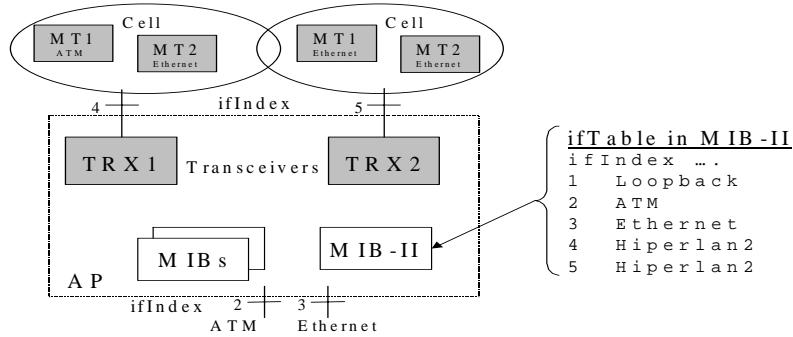

SNMPv1 provides an insecure environment. SNMPv3 adds security features. Implementors should consider using the User-based Security Model RFC 2574 [21] and the View-based Access Control Model RFC 2575 [24] of SNMPv3. The user should configure the system such way, that only authorized users have access to various parts of the MIB.

In case the SNMP framework only provides an insecure environment the implementors should consider to implement at least the H/2 security attributes with "MAX-ACCESS read-only" instead of "read-write", see annex B.

### 5.3 Overview

#### 5.3.1 AP System

Figure 1 shows an AP connected to an ATM network and to an Ethernet network. The AP contains two H/2 transceivers. Each transceiver is handling the radio traffic within its cell. The transceivers have different characteristics (configuration and behaviour) concerning H/2.

**Figure 1: H/2 AP**

The AP contains a number of MIBs, the set of these MIBs is vendor specific. It is however assumed that at least parts of MIB-II (the standard Internet MIB) is supported by the AP. The interface table of MIB-II contains one entry for each physical network interface of the AP including the H/2 radio interface(s). The interface table of MIB-II for this AP will look similar to the table shown in figure 1.

### 5.3.2 Overview of H/2 MIB (informative)

The H/2 MIB defined in the present document is intended to be placed in an AP. In the future the H/2 MIB can be placed in any H/2 device, i.e. any SNMP managed device with at least one H/2 interface. By excluding some groups and objects and by adding other groups and objects, the H/2 MIB can be adapted to any H/2 device type. The rest of this clause assumes that the device is an AP.

H/2 attributes common to the whole AP are located in a **H/2 System** group.

Besides the System group and the convergence layer group, the MIB is indexed to allow for one SNMP agent to support all transceivers in the AP. Index is ifIndex of the interface table of MIB-II.

**Addresses:** AP ID, NET ID, and NOP ID can be configured (set) via SNMP.

**Reset of H/2 Device:** it is possible to reset (restart) the whole H/2 device by setting h2SysReset. The AP and the H/2 interfaces handled by the AP are restarted. Restart can be used after a reconfiguration. How the configuration of a device is done is vendor specific but in order to have a consistent set of configuration parameter values following way of working can be used:

- the user sets the parameters one by one using SNMP, but the new parameter values are not yet in use;
- the device is restarted;
- the new parameter values are now used.

**Security:** encryption and authentication can be setup via SNMP. Default setup is encryption but no authentication.

There are interval values for unicast and common key refresh. The values can be changed if the default values are not acceptable.

The H/2 device supplies a list of supported encryption and authentication algorithms. There is also a list of used encryption and authentication algorithms. This list gives the preferred order of algorithms at association time. The used lists can be modified.

The CL group is a placeholder for the CL MIBs describing the CLs supported by the device.

A table is showing **handovers** from each neighbour cell. The table is built up from information at handover time. The table depicts how the MTs are moving to this cell from the neighbour cells.

**Utilization.** Number of currently associated MTs give hints on the usage of each H/2 interface. The peak number of associated MTs is kept and can be reset to the current number of associated MTs. The total number of associations is counted.

How the MAC frame is utilized is described by "%downlink usage" and "%uplink usage". These attributes indicate if all radio capacity is used or not.

The **MT table** describes and identifies all associated MTs. The latest RSS0 and RSS1 measurements of the MT are available (see [2]). The measurement values can be useful when troubleshooting.

Notifications (events) are sent (configurable) in case of a H/2 security violation (denied authentication), association failure, not normal disassociation, or failed handover. Information from the latest event of each type is also kept in MIB attributes.

**Time** attributes i.e. attributes with SYNTAX TimeTicks, see annex B, are given as number of time ticks (0,01s) since system start.

For more information on the MIB contents see annex B.

### 5.3.3 Relationships to other MIBs

#### 5.3.3.1 Common Definitions

All common H/2 definitions are specified in the module ETSI-H2-REG. This module contains mainly OIDs (Object Identifiers) to be used by the other H/2 modules. The other H/2 modules import used definitions from the definition module.

The H/2 MIBs are located within the HIPERLAN/2 area of the BRAN domain [9].

#### 5.3.3.2 Relationship to the CL MIBs

The CL MIBs are placed in the CL group of the H/2 MIB.

#### 5.3.3.3 Relationship to the "Interfaces" Group

Each H/2 radio interface shall be described by one entry in the interface table of MIB-II. The interface shall be described on DLC level i.e. independent of used CLs. See clause 4.3 for an example of an implementation.

### 5.3.4 Definitions to Import into a SNMP Manager (informative)

As an example, before managing a set of H/2 devices with an Ethernet interface following definitions should be imported into the SNMP manager:

- 1) ETSI-H2-REG containing common H/2 definitions;
- 2) ETSI-H2-MIB defining the H/2 main MIB;
- 3) ETSI-H2ETHCL-MIB defining the H/2 Ethernet CL MIB;
- 4) Any standard MIBs supported by the device and not yet imported into the SNMP manager;
- 5) Any vendor specific MIBs supported by the H/2 device.

## 5.4 Definitions

The definitions can be found in annexes A, B, C, and D.

---

## Annex A (normative): ETSI-H2-REG. Common Definitions Module
