Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: *"Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards"*, which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://ipr.etsi.org>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Satellite Earth Stations and Systems (SES).

The present document is specifying the Satellite Radio Interface referenced as SRI Family G at ITU-R, in the frame of the modification of ITU-R Recommendation M.1457 [i.5]. This modification has been approved at SG8 meeting in November 2005.

The present document is part 2, sub-part 3 of a multi-part deliverable covering Satellite Earth Stations and Systems (SES); Satellite Component of UMTS/IMT-2000; G-family enhancements, as identified below:

Part 1: "Physical channels and mapping of transport channels into physical channels";

Part 2: "Multiplexing and channel coding";

Sub-part 1: "G-family (S-UMTS-G 25.212)";

Sub-part 2: "A-family (S-UMTS-A 25.212)";

Sub-part 3: "G-family enhancements (S-UMTS-G enhanced 25.212)";

Part 3: "Spreading and modulation";

Part 4: "Physical layer procedures";

Part 5: "UE Radio Transmission and Reception";

Part 6: "Ground stations and space segment radio transmission and reception".

Introduction

S-UMTS stands for the Satellite component of the Universal Mobile Telecommunication System. S-UMTS systems will complement the Terrestrial UMTS (T-UMTS) and inter-work with other IMT-2000 family members through the UMTS core network. S-UMTS will be used to deliver 3rd generation Mobile Satellite Services (MSS) utilizing either low (LEO) or medium (MEO) earth orbiting, or geostationary (GEO) satellite(s). S-UMTS systems are based on terrestrial 3GPP specifications and will support access to GSM/UMTS core networks.

NOTE 1: The term T-UMTS will be used in the present document to further differentiate the Terrestrial UMTS component.

Due to the differences between terrestrial and satellite channel characteristics, some modifications to the terrestrial UMTS (T-UMTS) standards are necessary. Some specifications are directly applicable, whereas others are applicable with modifications. Similarly, some T-UMTS specifications do not apply, whilst some S-UMTS specifications have no corresponding T-UMTS specification.

Since S-UMTS is derived from T-UMTS, the organization of the S-UMTS specifications closely follows the original 3rd Generation Partnership Project (3GPP) structure. The S-UMTS numbers have been designed to correspond to the 3GPP terrestrial UMTS numbering system. All S-UMTS specifications are allocated a unique S-UMTS number as follows:

S-UMTS-n xx.yyy

Where:

- The numbers xx and yyy correspond to the 3GPP numbering scheme.
- n (n = A, B, C, etc.) denotes the family of S-UMTS specifications.

An S-UMTS system is defined by the combination of a family of S-UMTS specifications and 3GPP specifications, as follows:

- If an S-UMTS specification exists it takes precedence over the corresponding 3GPP specification (if any). This precedence rule applies to any references in the corresponding 3GPP specifications.

NOTE 2: Any references to 3GPP specifications within the S-UMTS specifications are not subject to this precedence rule.

EXAMPLE: An S-UMTS specification may contain specific references to the corresponding 3GPP specification.

- If an S-UMTS specification does not exist, the corresponding 3GPP specification may or may not apply. The exact applicability of the complete list of 3GPP specifications shall be defined at a later stage.

The present document is part of the S-UMT sub-part 3 specifications. Sub-part 3 specifications are identified in the title and can also be identified by the specification number:

- Sub-part 1 specifications have an S-UMTS-G prefix in the title and a sub-part number of "1" (TS 101 851-x-1).
- Sub-part 2 specifications have an S-UMTS-A prefix in the title and a sub-part number of "2" (TS 101 851-x-2).
- Sub-part 3 specifications have an S-UMTS-G enhanced prefix in the title and a sub-part number of "3" (TS 101 851-x-3).

The sub-part 1 specifications introduce the WCDMA satellite radio interface (ITU-R G-family) specifications for the third generation (3G) wireless communication systems. It is also based on the WCDMA UTRA FDD radio interface already standardized in 3GPP. Mobile satellite systems intending to use this interface will address user equipment fully compatible with 3GPP UTRA FDD WCDMA, with adaptation for agility to the Mobile Satellite Service (MSS) frequency band.

The sub-part 2 specifications introduce the SW-CDMA satellite radio interface (ITU-R A-family) specifications for third generation (3G) wireless communication systems. SW-CDMA is based on the adaptation to the satellite environment of terrestrial WCDMA. The intention is to reuse the same core network and reuse the radio interface specifications for the Is and Cu interface. Only the Uu interface is adapted to the satellite environment. SW-CDMA operates in FDD mode with RF channel bandwidth of either 2,350 MHz or 4,700 MHz for each transmission direction.

The sub-part 3 specifications introduce the WCDMA satellite radio interface enhancement (G enhance-family). It considers G-family as radio interface basis, adding as option selected enhancing features from ITU-R A and/or C-family in order to optimize the radio interface over satellite. It is based on the results of the TR 102 278 [i.6] identifying a way to achieve harmonization between A, C and G-family satellite radio interfaces for IMT-2000 in ITU-R.

The G-family enhancements made of A, C and G features are described in annex C.

The sub-parts 1 and 2 will be withdrawn if the A and C family will be removed from the satellite radio interface list of IMT-2000 in ITU-R Recommendation M.1850 [i.7] and then, the sub-part 3 will be revised.

1 Scope

The present document describes the characteristics of the Layer 1 multiplexing and channel coding used for family G enhanced of the satellite component of UMTS (S-UMTS-G enhanced).

It is based on the FDD mode of UTRA defined by TS 125 211 [i.1], TS 125 212 [i.2], TS 125 213 [i.3] and TS 125 214 [i.4] and adapted for operation over satellite transponders.

Furthermore, it specifies enhancing features optimizing the basic G family radio interface performances over satellite and new functions.

2 References

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the reference document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at <http://docbox.etsi.org/Reference>.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

2.1 Normative references

3 Definitions, symbols and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

Transmission Gap (TG): consecutive empty slots that have been obtained with a transmission time reduction method

NOTE: The transmission gap can be contained in one or two consecutive radio frames.

Transmission Gap Length (TGL): number of consecutive empty slots that have been obtained with a transmission time reduction method $0 \leq TGL \leq 14$

NOTE: The CFNs of the radio frames containing the first empty slot of the transmission gaps, the CFNs of the radio frames containing the last empty slot, the respective positions N_{first} and N_{last} within these frames of the first and last empty slots of the transmission gaps, and the transmission gap lengths can be calculated with the compressed mode parameters described in TS 125 215 [5].

TrCH number: transport channel number which identifies a TrCH in the context of L1

NOTE: The L3 transport channel identity (TrCH ID) maps onto the L1 transport channel number. The mapping between the transport channel number and the TrCH ID is as follows: TrCH 1 corresponds to the TrCH with the lowest TrCH ID, TrCH 2 corresponds to the TrCH with the next lowest TrCH ID and so on.

3.2 Symbols

For the purposes of the present document, the following symbols apply:

δ	DTX indication bits
$\lceil x \rceil$	round towards ∞ , i.e. integer such that $x \leq \lceil x \rceil < x + 1$
$\lfloor x \rfloor$	round towards $-\infty$, i.e. integer such that $x - 1 < \lfloor x \rfloor \leq x$
$ x $	absolute value of x
$\text{sgn}(x)$	signum function, i.e. $\text{sgn}(x) = \begin{cases} 1; & x \geq 0 \\ -1; & x < 0 \end{cases}$
N_{first}	The first slot in the <i>TG</i> , located in the first compressed radio frame if the <i>TG</i> spans two frames
N_{last}	The last slot in the <i>TG</i> , located in the second compressed radio frame if the <i>TG</i> spans two frames
N_{tr}	Number of transmitted slots in a radio frame

Unless otherwise is explicitly stated when the symbol is used, the meaning of the following symbols is:

i	TrCH number
j	TFC number
k	Bit number
l	TF number
m	Transport block number
n_i	Radio frame number of TrCH i
p	PhCH number
r	Code block number
I	Number of TrCHs in a CCTrCH
C_i	Number of code blocks in one TTI of TrCH i
F_i	Number of radio frames in one TTI of TrCH i
M_i	Number of transport blocks in one TTI of TrCH i
$N_{\text{data},j}$	Number of data bits that are available for the CCTrCH in a radio frame with TFC j
$N_{\text{data},j}^{\text{cm}}$	Number of data bits that are available for the CCTrCH in a compressed radio frame with TFC j
P	Number of PhCHs used for one CCTrCH
PL	Puncturing Limit for the uplink. Signalled from higher layers
RM_i	Rate Matching attribute for TrCH i . Signalled from higher layers

Temporary variables, i.e. variables used in several clauses with different meaning:

x, X
 y, Y
 z, Z

3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

BCH	Broadcast CHannel
BER	Bit Error Rate
CCPCH	Common Control Physical CHannel
CCTrCH	Coded Composite Transport CHannel
CFN	Connection Frame Number
CRC	Cyclic Redundancy Check
DCH	Dedicated CHannel

DL	DownLink (Forward link)
DPCCCH	Dedicated Physical Control CHannel
DPCH	Dedicated Physical CHannel
DPDCH	Dedicated Physical Data CHannel
DTX	Discontinuous Transmission
FACH	Forward Access CHannel
FBI	FeedBack Indicator
FDD	Frequency Division Duplex
FDD	Frequency Division Duplexing
FER	Frame Error Rate
GEO	Geostationary Earth Orbit
GF	Galois Field
GSM	Global Systems for Mobile communications
LEO	Low Earth Orbit
LSB	Least Significant Bit
MAC	Medium Access Control
MEO	Medium Earth Orbit
ML	Maximum Likelihood
MSB	Most Significant Bit
MSS	Mobile Satellite Services
PCCC	Parallel Concatenated Convolutional Code
PCH	Paging CHannel
PhCH	Physical CHannel
PL	Puncturing Limit
PRACH	Physical Random Access CHannel
RACH	Random Access CHannel
RF	Radio Frequency
RM	Rate Matching
S-CCPCH	Secondary Common Control Physical CHannel
SF	Spreading Factor
SRI	Satellite Radio Interface
SSDT	Satellite Spot Diversity Transmission
S-UMTS	Satellite Universal Mobile Telecommunication Systems
SW-CDMA	Satellite Wideband Code Division Multiple Access
TF	Transport Format
TFC	Transport Format Combination
TFCI	Transport Format Combination Indicator
TFCS	Transmit Format Combination Set
TG	Transmission Gap
TGL	Transmission Gap Length
TPC	Transmit Power Control
TrCH	Transport CHannel
TTI	Transmission Time Interval
T-UMTS	Terrestrial Universal Mobile Telecommunications System
UL	UpLink (Reverse link)
USRAN	UMTS Satellite Radio Access Network
UTRA	UMTS Terrestrial Radio Access
UTRA	UMTS Terrestrial Radio Access
WCDMA	Wideband Code Division Multiple Access

4 Multiplexing, channel coding and interleaving

4.1 General

Data stream from/to MAC and higher layers (Transport block/Transport block set) is encoded/decoded to offer transport services over the radio transmission link. Channel coding scheme is a combination of error detection, error correcting, rate matching, interleaving and transport channels mapping onto/splitting from physical channels.

4.2 General coding/multiplexing of TrCHs

This clause only applies to the transport channels:

- DCH;
- RACH;
- BCH;
- FACH; and
- PCH.

Other transport channels which do not use the general method are described separately below.

Data arrives to the coding/multiplexing unit in form of transport block sets once every transmission time interval. The transmission time interval is transport-channel specific from the set {10 ms, 20 ms, 40 ms, 80 ms}.

The following coding/multiplexing steps can be identified:

- add CRC to each transport block (see clause 4.2.1);
- transport block concatenation and code block segmentation (see clause 4.2.2);
- channel coding (see clause 4.2.3);
- radio frame equalization (see clause 4.2.4);
- rate matching (see clause 4.2.7);
- insertion of discontinuous transmission (DTX) indication bits (see clause 4.2.9);
- interleaving (two steps, see clauses 4.2.5 and 4.2.11);
- radio frame segmentation (see clause 4.2.6);
- multiplexing of transport channels (see clause 4.2.8);
- physical channel segmentation (see clause 4.2.10);
- mapping to physical channels (see clause 4.2.12);
- data scrambling (only for downlink, and optional) (see clause 4.2.15).

The coding/multiplexing steps for uplink and downlink are shown in figures 1 and 2 respectively (N.B. figure 1 and 2a applies for optional mode A).

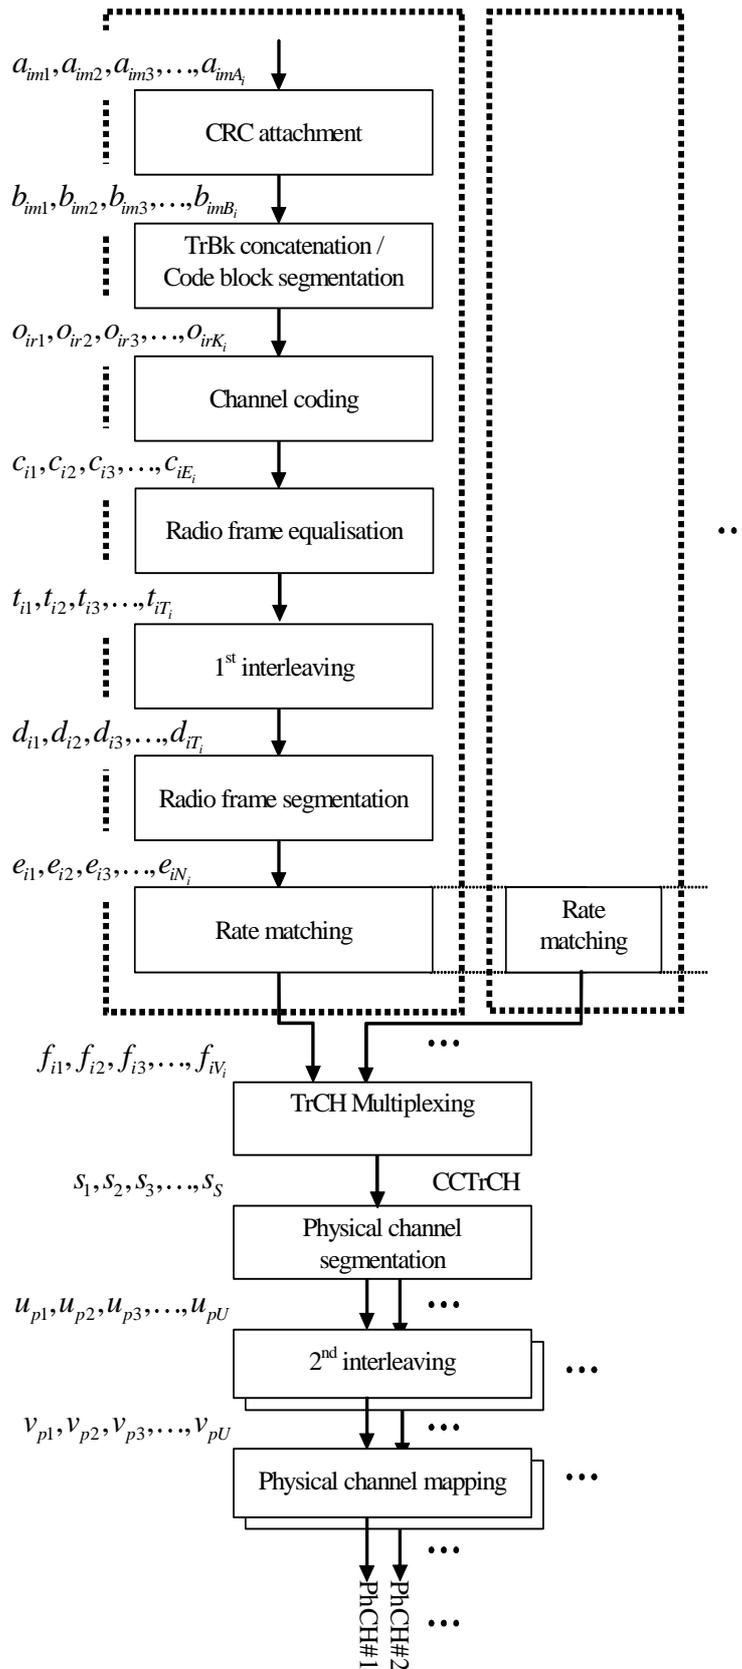

Figure 1: Transport channel multiplexing structure for uplink

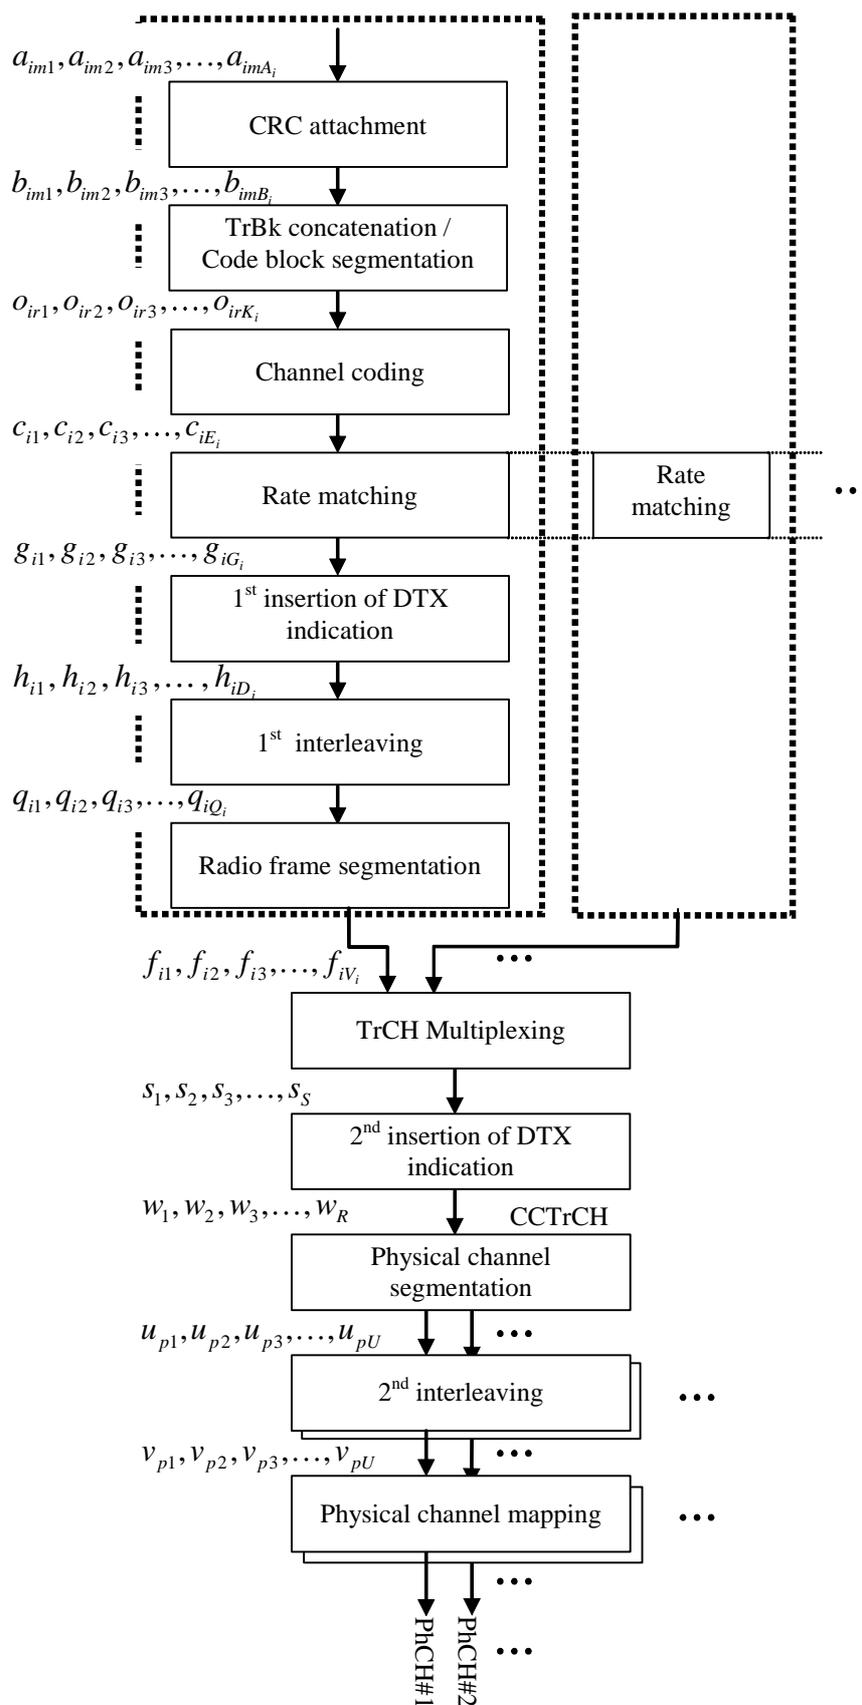

Figure 2: Transport channel multiplexing structure for downlink

The single output data stream from the TrCH multiplexing, including DTX indication bits in downlink, is denoted *Coded Composite Transport Channel (CCTrCH)*. A CCTrCH can be mapped to one or several physical channels.

In optional mode A, the following is applied with the addition of add a scrambling step (in bold in the figure) for downlink:

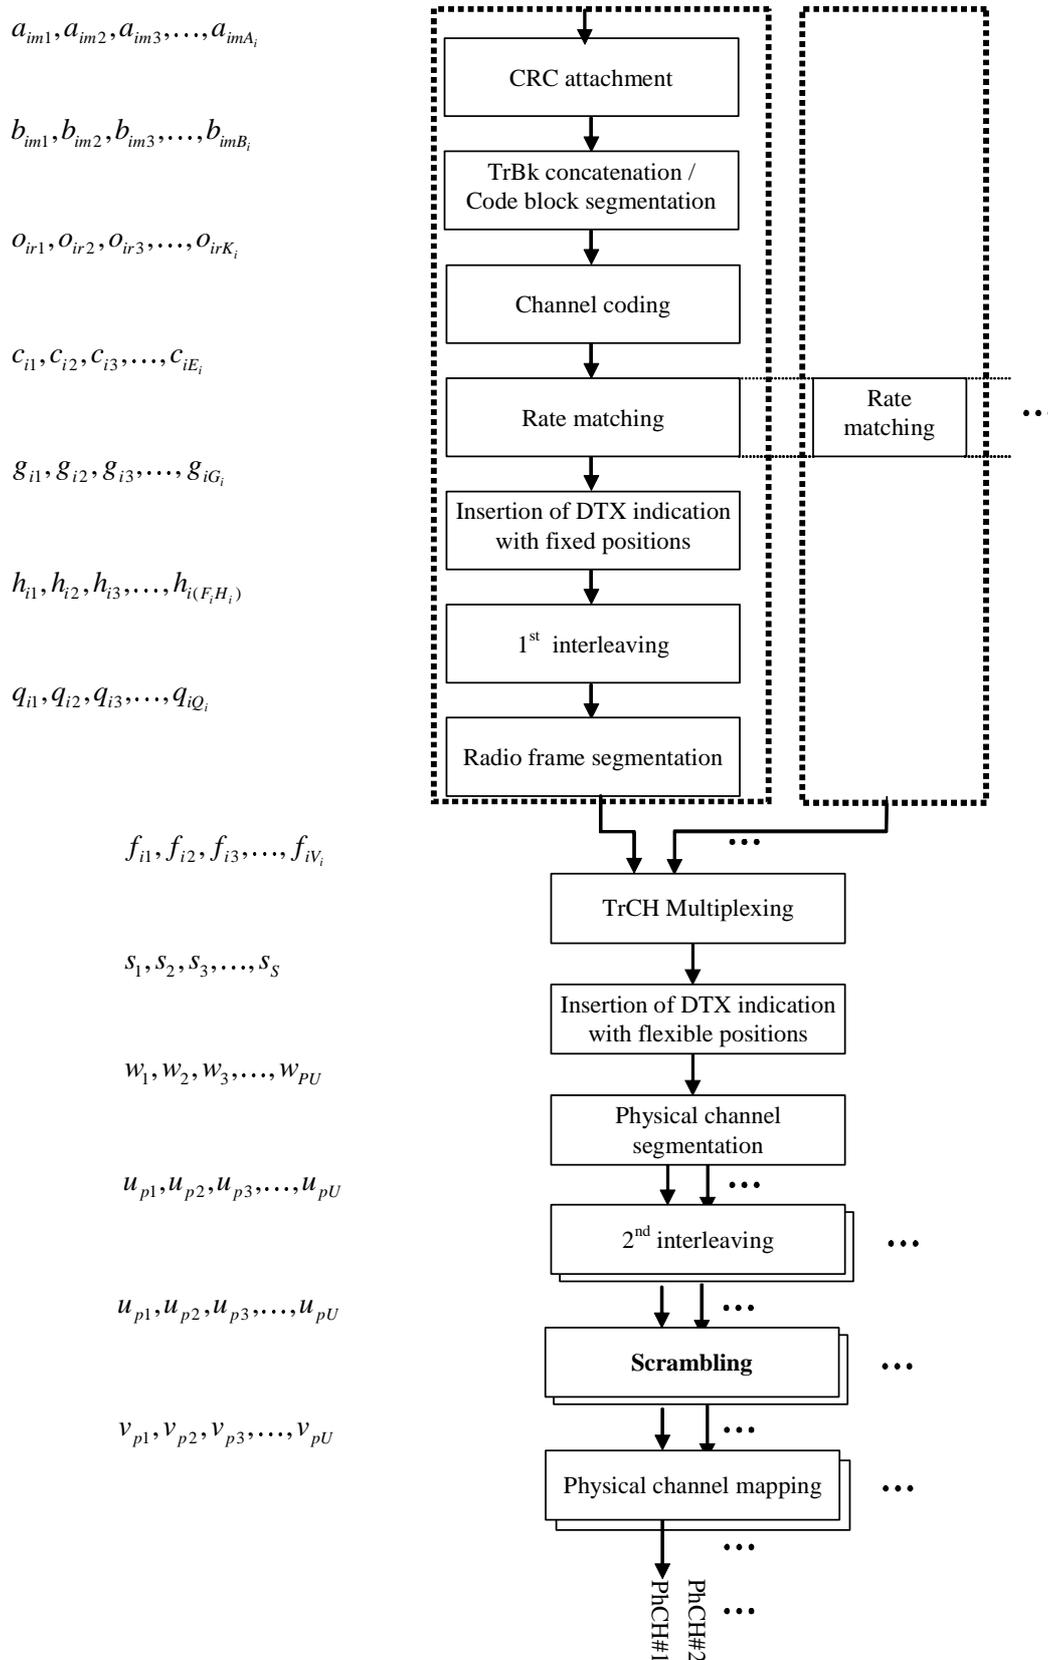

Figure 2a: Transport channel multiplexing structure for downlink (Optional mode A)

4.2.1 CRC attachment

Error detection is provided on transport blocks through a Cyclic Redundancy Check (CRC). The size of the CRC is 24 bits, 16 bits, 12 bits, 8 bits or 0 bit and it is signalled from higher layers what CRC size that should be used for each TrCH.

4.2.1.1 CRC Calculation

The entire transport block is used to calculate the CRC parity bits for each transport block. The parity bits are generated by one of the following cyclic generator polynomials:

- $g_{\text{CRC24}}(D) = D^{24} + D^{23} + D^6 + D^5 + D + 1$;
- $g_{\text{CRC16}}(D) = D^{16} + D^{12} + D^5 + 1$;
- $g_{\text{CRC12}}(D) = D^{12} + D^{11} + D^3 + D^2 + D + 1$;
- $g_{\text{CRC8}}(D) = D^8 + D^7 + D^4 + D^3 + D + 1$.

Denote the bits in a transport block delivered to layer 1 by $a_{im1}, a_{im2}, a_{im3}, \dots, a_{imA_i}$, and the parity bits by $p_{im1}, p_{im2}, p_{im3}, \dots, p_{imL_i}$. A_i is the size of a transport block of TrCH i , m is the transport block number, and L_i is the number of parity bits. L_i can take the values 24, 16, 12, 8, or 0 depending on what is signalled from higher layers.

The encoding is performed in a systematic form, which means that in GF(2), the polynomial:

$$a_{im1}D^{A_i+23} + a_{im2}D^{A_i+22} + \dots + a_{imA_i}D^{24} + p_{im1}D^{23} + p_{im2}D^{22} + \dots + p_{im23}D^1 + p_{im24}$$

yields a remainder equal to 0 when divided by $g_{\text{CRC24}}(D)$, polynomial:

$$a_{im1}D^{A_i+15} + a_{im2}D^{A_i+14} + \dots + a_{imA_i}D^{16} + p_{im1}D^{15} + p_{im2}D^{14} + \dots + p_{im15}D^1 + p_{im16}$$

yields a remainder equal to 0 when divided by $g_{\text{CRC16}}(D)$, polynomial:

$$a_{im1}D^{A_i+11} + a_{im2}D^{A_i+10} + \dots + a_{imA_i}D^{12} + p_{im1}D^{11} + p_{im2}D^{10} + \dots + p_{im11}D^1 + p_{im12}$$

yields a remainder equal to 0 when divided by $g_{\text{CRC12}}(D)$ and polynomial:

$$a_{im1}D^{A_i+7} + a_{im2}D^{A_i+6} + \dots + a_{imA_i}D^8 + p_{im1}D^7 + p_{im2}D^6 + \dots + p_{im7}D^1 + p_{im8}$$

yields a remainder equal to 0 when divided by $g_{\text{CRC8}}(D)$.

If no transport blocks are input to the CRC calculation ($M_i = 0$), no CRC attachment shall be done. If transport blocks are input to the CRC calculation ($M_i \neq 0$) and the size of a transport block is zero ($A_i = 0$), CRC shall be attached, i.e. all parity bits equal to zero.

4.2.1.2 Relation between input and output of the CRC attachment block

The bits after CRC attachment are denoted by $b_{im1}, b_{im2}, b_{im3}, \dots, b_{imB_i}$, where $B_i = A_i + L_i$. The relation between a_{imk} and b_{imk} is:

$$\begin{aligned} b_{imk} &= a_{imk} & k &= 1, 2, 3, \dots, A_i \\ b_{imk} &= p_{im(L_i+1-(k-A_i))} & k &= A_i + 1, A_i + 2, A_i + 3, \dots, A_i + L_i \end{aligned}$$

4.2.2 Transport block concatenation and code block segmentation

All transport blocks in a TTI are serially concatenated. If the number of bits in a TTI is larger than Z , the maximum size of a code block in question, then code block segmentation is performed after the concatenation of the transport blocks. The maximum size of the code blocks depends on whether convolutional coding or turbo coding is used for the TrCH.

4.2.2.1 Concatenation of transport blocks

The bits input to the transport block concatenation are denoted by $b_{im1}, b_{im2}, b_{im3}, \dots, b_{imB_i}$ where i is the TrCH number, m is the transport block number, and B_i is the number of bits in each block (including CRC). The number of transport blocks on TrCH i is denoted by M_i . The bits after concatenation are denoted by $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$, where i is the TrCH number and $X_i = M_i B_i$. They are defined by the following relations:

$$\begin{aligned}
 x_{ik} &= b_{i1k} & k &= 1, 2, \dots, B_i \\
 x_{ik} &= b_{i,2,(k-B_i)} & k &= B_i + 1, B_i + 2, \dots, 2B_i \\
 x_{ik} &= b_{i,3,(k-2B_i)} & k &= 2B_i + 1, 2B_i + 2, \dots, 3B_i \\
 & & & \dots \\
 x_{ik} &= b_{i,M_i,(k-(M_i-1)B_i)} & k &= (M_i - 1)B_i + 1, (M_i - 1)B_i + 2, \dots, M_i B_i.
 \end{aligned}$$

4.2.2.2 Code block segmentation

Segmentation of the bit sequence from transport block concatenation is performed if $X_i > Z$. The code blocks after segmentation are of the same size. The number of code blocks on TrCH i is denoted by C_i . If the number of bits input to the segmentation, X_i , is not a multiple of C_i , filler bits are added to the beginning of the first block. If turbo coding is selected and $X_i < 40$, filler bits are added to the beginning of the code block. The filler bits are transmitted and they are always set to 0. The maximum code block sizes are:

- convolutional coding: $Z = 504$;
- turbo coding: $Z = 5\ 114$.

The bits output from code block segmentation, for $C_i \neq 0$, are denoted by $o_{ir1}, o_{ir2}, o_{ir3}, \dots, o_{irK_i}$, where i is the TrCH number, r is the code block number, and K_i is the number of bits per code block.

Number of code blocks:

$$C_i = \lceil X_i / Z \rceil$$

Number of bits in each code block (applicable for $C_i \neq 0$ only):

if $X_i < 40$ and Turbo coding is used, then

$$K_i = 40$$

else

$$K_i = \lceil X_i / C_i \rceil$$

endif

Number of filler bits: $Y_i = C_i K_i - X_i$

```

for  $k = 1$  to  $Y_i$            -- Insertion of filler bits
     $o_{i1k} = 0$ 
end for
for  $k = Y_i + 1$  to  $K_i$ 
     $o_{i1k} = x_{i,(k-Y_i)}$ 
end for
 $r = 2$                        -- Segmentation
while  $r \leq C_i$ 
    for  $k = 1$  to  $K_i$ 
         $o_{irk} = x_{i,(k+(r-1) \cdot K_i - Y_i)} I$ 
    end for
     $r = r + 1$ 
end while

```

4.2.3 Channel coding

Code blocks are delivered to the channel coding block. They are denoted by $o_{ir1}, o_{ir2}, o_{ir3}, \dots, o_{irK_i}$, where i is the TrCH number, r is the code block number, and K_i is the number of bits in each code block. The number of code blocks on TrCH i is denoted by C_i . After encoding the bits are denoted by $y_{ir1}, y_{ir2}, y_{ir3}, \dots, y_{irY_i}$, where Y_i is the number of encoded bits. The relation between o_{irk} and y_{irk} and between K_i and Y_i is dependent on the channel coding scheme.

The following channel coding schemes can be applied to TrCHs:

- convolutional coding;
- turbo coding.

Usage of coding scheme and coding rate for the different types of TrCH is shown in table 1.

The values of Y_i in connection with each coding scheme:

- convolutional coding with rate 1/2: $Y_i = 2 \times K_i + 16$; rate 1/3: $Y_i = 3 \times K_i + 24$;
- turbo coding with rate 1/3: $Y_i = 3 \times K_i + 12$.

Table 1: Usage of channel coding scheme and coding rate

Type of TrCH	Coding scheme	Coding rate
BCH	Convolutional coding	1/2
PCH		
RACH		
DCH, FACH	Turbo coding	1/3, 1/2
		1/3

4.2.3.1 Convolutional coding

Convolutional codes with constraint length 9 and coding rates 1/3 and 1/2 are defined.

The configuration of the convolutional coder is presented in figure 3.

Output from the rate 1/3 convolutional coder shall be done in the order output 0, output 1, output 2, output 0, output 1, output 2, output 0, ..., output 2. Output from the rate 1/2 convolutional coder shall be done in the order output 0, output 1, output 0, output 1, output 0, ..., output 1.

8 tail bits with binary value 0 shall be added to the end of the code block before encoding.

The initial value of the shift register of the coder shall be "all 0" when starting to encode the input bits.

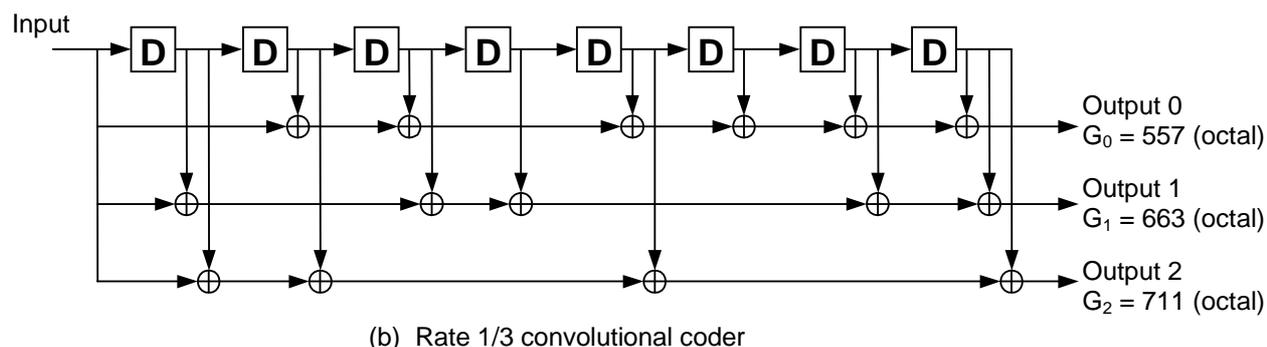

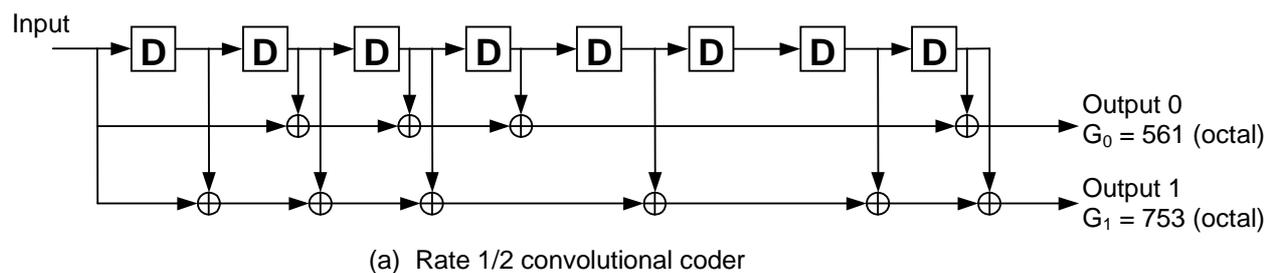

Figure 3: Rate 1/2 and rate 1/3 convolutional coders

4.2.3.2 Turbo coding

4.2.3.2.1 Turbo coder

The scheme of Turbo coder is a Parallel Concatenated Convolutional Code (PCCC) with two 8-state constituent encoders and one Turbo code internal interleaver. The coding rate of Turbo coder is 1/3. The structure of Turbo coder is illustrated in figure 4.

The transfer function of the 8-state constituent code for PCCC is:

$$G(D) = \left[1, \frac{g_1(D)}{g_0(D)} \right],$$

where

$$g_0(D) = 1 + D^2 + D^3,$$

$$g_1(D) = 1 + D + D^3.$$

The initial value of the shift registers of the 8-state constituent encoders shall be all zeros when starting to encode the input bits.

Output from the Turbo coder is:

$$x_1, z_1, z'_1, x_2, z_2, z'_2, \dots, x_K, z_K, z'_K,$$

where x_1, x_2, \dots, x_K are the bits input to the Turbo coder i.e. both first 8-state constituent encoder and Turbo code internal interleaver, and K is the number of bits, and z_1, z_2, \dots, z_K and z'_1, z'_2, \dots, z'_K are the bits output from first and second 8-state constituent encoders, respectively.

The bits output from Turbo code internal interleaver are denoted by x'_1, x'_2, \dots, x'_K , and these bits are to be input to the second 8-state constituent encoder.

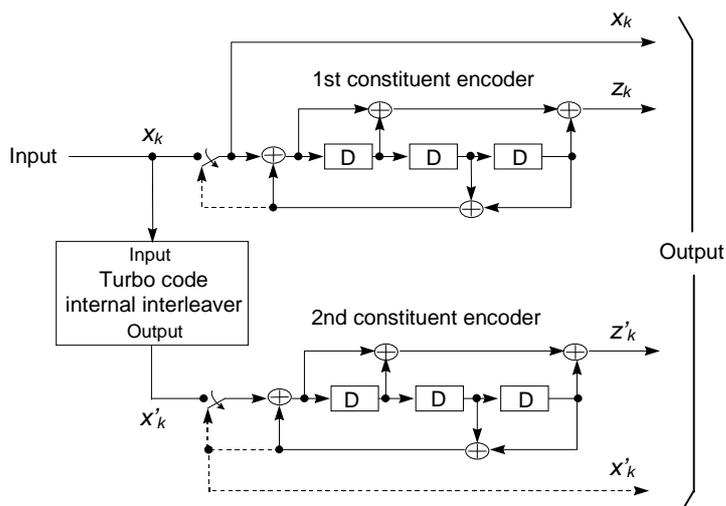

Figure 4: Structure of rate 1/3 Turbo coder (dotted lines apply for trellis termination only)

4.2.3.2.2 Trellis termination for Turbo coder

Trellis termination is performed by taking the tail bits from the shift register feedback after all information bits are encoded. Tail bits are padded after the encoding of information bits.

The first three tail bits shall be used to terminate the first constituent encoder (upper switch of figure 4 in lower position) while the second constituent encoder is disabled. The last three tail bits shall be used to terminate the second constituent encoder (lower switch of figure 4 in lower position) while the first constituent encoder is disabled.

The transmitted bits for trellis termination shall then be:

$$x_{K+1}, z_{K+1}, x_{K+2}, z_{K+2}, x_{K+3}, z_{K+3}, x'_{K+1}, z'_{K+1}, x'_{K+2}, z'_{K+2}, x'_{K+3}, z'_{K+3}.$$

4.2.3.2.3 Turbo code internal interleaver

The Turbo code internal interleaver consists of bits-input to a rectangular matrix with padding, intra-row and inter-row permutations of the rectangular matrix, and bits-output from the rectangular matrix with pruning. The bits input to the Turbo code internal interleaver are denoted by $x_1, x_2, x_3, \dots, x_K$, where K is the integer number of the bits and takes one value of $40 \leq K \leq 5114$. The relation between the bits input to the Turbo code internal interleaver and the bits input to the channel coding is defined by $x_k = O_{irk}$ and $K = K_i$.

The following clause specific symbols are used in clauses 4.2.3.2.3.1 to 4.2.3.2.3.3:

K	Number of bits input to Turbo code internal interleaver
R	Number of rows of rectangular matrix
C	Number of columns of rectangular matrix
p	Prime number
v	Primitive root
$\langle s(j) \rangle_{j \in \{0,1,\dots,p-2\}}$	Base sequence for intra-row permutation
q_i	Minimum prime integers
r_i	Permuted prime integers
$\langle T(i) \rangle_{i \in \{0,1,\dots,R-1\}}$	Inter-row permutation pattern
$\langle U_i(j) \rangle_{j \in \{0,1,\dots,C-1\}}$	Intra-row permutation pattern of i -th row
i	Index of row number of rectangular matrix
j	Index of column number of rectangular matrix
k	Index of bit sequence

4.2.3.2.3.1 Bits-input to rectangular matrix with padding

The bit sequence $x_1, x_2, x_3, \dots, x_K$ input to the Turbo code internal interleaver is written into the rectangular matrix as follows:

- 1) Determine the number of rows of the rectangular matrix, R , such that:

$$R = \begin{cases} 5, & \text{if } (40 \leq K \leq 159) \\ 10, & \text{if } ((160 \leq K \leq 200) \text{ or } (481 \leq K \leq 530)) \\ 20, & \text{if } (K = \text{any other value}) \end{cases} .$$

The rows of rectangular matrix are numbered $0, 1, \dots, R - 1$ from top to bottom.

- 2) Determine the prime number to be used in the intra-permutation, p , and the number of columns of rectangular matrix, C , such that:

if $(481 \leq K \leq 530)$ then

$$p = 53 \text{ and } C = p.$$

else

Find minimum prime number p from table 2 such that:

$$K \leq R \times (p + 1),$$

and determine C such that:

$$C = \begin{cases} p - 1 & \text{if } K \leq R \times (p - 1) \\ p & \text{if } R \times (p - 1) < K \leq R \times p \\ p + 1 & \text{if } R \times p < K \end{cases} .$$

endif

The columns of rectangular matrix are numbered 0, 1, ..., $C - 1$ from left to right.

Table 2: List of prime number p and associated primitive root v

p	v								
7	3	47	5	101	2	157	5	223	3
11	2	53	2	103	5	163	2	227	2
13	2	59	2	107	2	167	5	229	6
17	3	61	2	109	6	173	2	233	3
19	2	67	2	113	3	179	2	239	7
23	5	71	7	127	3	181	2	241	7
29	2	73	5	131	2	191	19	251	6
31	3	79	3	137	3	193	5	257	3
37	2	83	2	139	2	197	2		
41	6	89	3	149	2	199	3		
43	3	97	5	151	6	211	2		

- 3) Write the input bit sequence $x_1, x_2, x_3, \dots, x_K$ into the $R \times C$ rectangular matrix row by row starting with bit y_1 in column 0 of row 0:

$$\begin{bmatrix} y_1 & y_2 & y_3 & \dots & y_C \\ y_{(C+1)} & y_{(C+2)} & y_{(C+3)} & \dots & y_{2C} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{((R-1)C+1)} & y_{((R-1)C+2)} & y_{((R-1)C+3)} & \dots & y_{R \times C} \end{bmatrix}$$

where $y_k = x_k$ for $k = 1, 2, \dots, K$ and if $R \times C > K$, the dummy bits are padded such that $y_k = 0$ or 1 for $k = K + 1, K + 2, \dots, R \times C$. These dummy bits are pruned away from the output of the rectangular matrix after intra-row and inter-row permutations.

4.2.3.2.3.2 Intra-row and inter-row permutations

After the bits-input to the $R \times C$ rectangular matrix, the intra-row and inter-row permutations for the $R \times C$ rectangular matrix are performed stepwise by using the following algorithm with steps 1) to 6):

- 1) Select a primitive root v from table 2 in clause 4.2.3.2.3.1, which is indicated on the right side of the prime number p .
- 2) Construct the base sequence $\langle s(j) \rangle_{j \in \{0, 1, \dots, p-2\}}$ for intra-row permutation as:
$$s(j) = (v \times s(j-1)) \bmod p, \quad j = 1, 2, \dots, (p-2), \text{ and } s(0) = 1.$$
- 3) Assign $q_0 = 1$ to be the first prime integer in the sequence $\langle q_i \rangle_{i \in \{0, 1, \dots, R-1\}}$, and determine the prime integer q_i in the sequence $\langle q_i \rangle_{i \in \{0, 1, \dots, R-1\}}$ to be a least prime integer such that $\text{g.c.d.}(q_i, p-1) = 1$, $q_i > 6$, and $q_i > q_{(i-1)}$ for each $i = 1, 2, \dots, R-1$. Here g.c.d. is greatest common divisor.
- 4) Permute the sequence $\langle q_i \rangle_{i \in \{0, 1, \dots, R-1\}}$ to make the sequence $\langle r_i \rangle_{i \in \{0, 1, \dots, R-1\}}$ such that:

$$r_{T(i)} = q_i, \quad i = 0, 1, \dots, R-1,$$

where $\langle T(i) \rangle_{i \in \{0, 1, \dots, R-1\}}$ is the inter-row permutation pattern defined as the one of the four kinds of patterns, which are shown in table 3, depending on the number of input bits K .

Table 3: Inter-row permutation patterns for Turbo code internal interleaver

Number of input bits K	Number of rows R	Inter-row permutation patterns $\langle T(0), T(1), \dots, T(R-1) \rangle$
$(40 \leq K \leq 159)$	5	$\langle 4, 3, 2, 1, 0 \rangle$
$(160 \leq K \leq 200)$ or $(481 \leq K \leq 530)$	10	$\langle 9, 8, 7, 6, 5, 4, 3, 2, 1, 0 \rangle$
$(2\,281 \leq K \leq 2\,480)$ or $(3\,161 \leq K \leq 3\,210)$	20	$\langle 19, 9, 14, 4, 0, 2, 5, 7, 12, 18, 16, 13, 17, 15, 3, 1, 6, 11, 8, 10 \rangle$
$K = \text{any other value}$	20	$\langle 19, 9, 14, 4, 0, 2, 5, 7, 12, 18, 10, 8, 13, 17, 3, 1, 16, 6, 15, 11 \rangle$

5) Perform the i -th ($i = 0, 1, \dots, R - 1$) intra-row permutation as:

if ($C = p$) then

$$U_i(j) = s((j \times r_i) \bmod (p-1)), j = 0, 1, \dots, (p-2), \text{ and } U_i(p-1) = 0,$$

where $U_i(j)$ is the original bit position of j -th permuted bit of i -th row.

endif

if ($C = p + 1$) then

$$U_i(j) = s((j \times r_i) \bmod (p-1)), j = 0, 1, \dots, (p-2). U_i(p-1) = 0, \text{ and } U_i(p) = p,$$

where $U_i(j)$ is the original bit position of j -th permuted bit of i -th row, and

if ($K = R \times C$) then

Exchange $U_{R-1}(p)$ with $U_{R-1}(0)$.

endif

endif

if ($C = p - 1$) then

$$U_i(j) = s((j \times r_i) \bmod (p-1)) - 1, j = 0, 1, \dots, (p-2),$$

where $U_i(j)$ is the original bit position of j -th permuted bit of i -th row.

endif

6) Perform the inter-row permutation for the rectangular matrix based on the pattern $\langle T(i) \rangle_{i \in \{0,1,\dots,R-1\}}$,

where $T(i)$ is the original row position of the i -th permuted row.

4.2.3.2.3.3 Bits-output from rectangular matrix with pruning

After intra-row and inter-row permutations, the bits of the permuted rectangular matrix are denoted by y'_k :

$$\begin{bmatrix} y'_1 & y'_{(R+1)} & y'_{(2R+1)} & \cdots & y'_{((C-1)R+1)} \\ y'_2 & y'_{(R+2)} & y'_{(2R+2)} & \cdots & y'_{((C-1)R+2)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ y'_R & y'_{2R} & y'_{3R} & \cdots & y'_{C \times R} \end{bmatrix}$$

The output of the Turbo code internal interleaver is the bit sequence read out column by column from the intra-row and inter-row permuted $R \times C$ rectangular matrix starting with bit y'_1 in row 0 of column 0 and ending with bit y'_{CR} in row $R - 1$ of column $C - 1$. The output is pruned by deleting dummy bits that were padded to the input of the rectangular matrix before intra-row and inter row permutations, i.e. bits y'_k that corresponds to bits y_k with $k > K$ are removed from the output. The bits output from Turbo code internal interleaver are denoted by x'_1, x'_2, \dots, x'_K , where x'_1 corresponds to the bit y'_k with smallest index k after pruning, x'_2 to the bit y'_k with second smallest index k after pruning, and so on. The number of bits output from Turbo code internal interleaver is K and the total number of pruned bits is:

$$R \times C - K.$$

4.2.3.3 Concatenation of encoded blocks

After the channel coding for each code block, if C_i is greater than 1, the encoded blocks are serially concatenated so that the block with lowest index r is output first from the channel coding block, otherwise the encoded block is output from channel coding block as it is. The bits output are denoted by $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$, where i is the TrCH number and $E_i = C_i Y_i$. The output bits are defined by the following relations:

$$\begin{aligned} c_{ik} &= y_{i1k} & k &= 1, 2, \dots, Y_i \\ c_{ik} &= y_{i,2,(k-Y_i)} & k &= Y_i + 1, Y_i + 2, \dots, 2Y_i \\ c_{ik} &= y_{i,3,(k-2Y_i)} & k &= 2Y_i + 1, 2Y_i + 2, \dots, 3Y_i \\ & \dots & & \\ c_{ik} &= y_{i,C_i,(k-(C_i-1)Y_i)} & k &= (C_i - 1)Y_i + 1, (C_i - 1)Y_i + 2, \dots, C_i Y_i \end{aligned}$$

If no code blocks are input to the channel coding ($C_i = 0$), no bits shall be output from the channel coding, i.e. $E_i = 0$.

4.2.4 Radio frame size equalization

Radio frame size equalization is padding the input bit sequence in order to ensure that the output can be segmented in F_i data segments of same size as described in clause 4.2.4. Radio frame size equalization is only performed in the UL.

The input bit sequence to the radio frame size equalization is denoted by $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$, where i is TrCH number and E_i the number of bits. The output bit sequence is denoted by $t_{i1}, t_{i2}, t_{i3}, \dots, t_{iT_i}$, where T_i is the number of bits. The output bit sequence is derived as follows:

$$\begin{aligned} t_{ik} &= c_{ik}, \text{ for } k = 1 \dots E_i; \text{ and} \\ t_{ik} &= \{0, 1\} \text{ for } k = E_i + 1 \dots T_i, \text{ if } E_i < T_i; \end{aligned}$$

where

$$T_i = F_i \times N_i; \text{ and}$$

$N_i = \lceil E_i / F_i \rceil$ is the number of bits per segment after size equalization.

4.2.5 1st interleaving

In Compressed Mode by puncturing, bits marked with a fourth value on top of $\{0, 1, \delta\}$ and noted p, are introduced in the radio frames to be compressed, in positions corresponding to the first bits of the radio frames. They will be removed in a later stage of the multiplexing chain to create the actual gap. Additional puncturing has been performed in the rate matching step, over the TTI containing the compressed radio frame, to create room for these p-bits. The following clause describes this feature.

4.2.5.2 1st interleaver operation

The 1st interleaving is a block interleaver with inter-column permutations. The input bit sequence to the block interleaver is denoted by $x_{i,1}, x_{i,2}, x_{i,3}, \dots, x_{i,X_i}$, where i is TrCH number and X_i the number of bits. Here X_i is guaranteed to be an integer multiple of the number of radio frames in the TTI. The output bit sequence from the block interleaver is derived as follows:

- 1) Select the number of columns $C1$ from table 4 depending on the TTI. The columns are numbered $0, 1, \dots, C1 - 1$ from left to right.
- 2) Determine the number of rows of the matrix, $R1$ defined as:

$$R1 = X_i / C1.$$

The rows of the matrix are numbered $0, 1, \dots, R1 - 1$ from top to bottom.

- 3) Write the input bit sequence into the $R1 \times C1$ matrix row by row starting with bit $x_{i,1}$ in column 0 of row 0 and ending with bit $x_{i,(R1 \times C1)}$ in column $C1 - 1$ of row $R1 - 1$:

$$\begin{bmatrix} x_{i,1} & x_{i,2} & x_{i,3} & \dots & x_{i,C1} \\ x_{i,(C1+1)} & x_{i,(C1+2)} & x_{i,(C1+3)} & \dots & x_{i,(2 \times C1)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ x_{i,((R1-1) \times C1+1)} & x_{i,((R1-1) \times C1+2)} & x_{i,((R1-1) \times C1+3)} & \dots & x_{i,(R1 \times C1)} \end{bmatrix}$$

- 4) Perform the inter-column permutation for the matrix based on the pattern $\langle P1_{C1}(j) \rangle_{j \in \{0,1,\dots,C1-1\}}$ shown in table 4, where $P1_{C1}(j)$ is the original column position of the j -th permuted column. After permutation of the columns, the bits are denoted by y_{ik} :

$$\begin{bmatrix} y_{i,1} & y_{i,(R1+1)} & y_{i,(2 \times R1+1)} & \dots & y_{i,((C1-1) \times R1+1)} \\ y_{i,2} & y_{i,(R1+2)} & y_{i,(2 \times R1+2)} & \dots & y_{i,((C1-1) \times R1+2)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{i,R1} & y_{i,(2 \times R1)} & y_{i,(3 \times R1)} & \dots & y_{i,(C1 \times R1)} \end{bmatrix}$$

- 5) Read the output bit sequence $y_{i,1}, y_{i,2}, y_{i,3}, \dots, y_{i,(C1 \times R1)}$ of the block interleaver column by column from the inter-column permuted $R1 \times C1$ matrix. Bit $y_{i,1}$ corresponds to row 0 of column 0 and bit $y_{i,(R1 \times C1)}$ corresponds to row $R1 - 1$ of column $C1 - 1$.

Table 4: Inter-column permutation patterns for 1st interleaving

TTI	Number of columns $C1$	Inter-column permutation patterns $\langle P1_{C1}(0), P1_{C1}(1), \dots, P1_{C1}(C1-1) \rangle$
10 ms	1	$\langle 0 \rangle$
20 ms	2	$\langle 0, 1 \rangle$
40 ms	4	$\langle 0, 2, 1, 3 \rangle$
80 ms	8	$\langle 0, 4, 2, 6, 1, 5, 3, 7 \rangle$

4.2.5.3 Relation between input and output of 1st interleaving in uplink

The bits input to the 1st interleaving are denoted by $t_{i,1}, t_{i,2}, t_{i,3}, \dots, t_{i,T_i}$, where i is the TrCH number and T_i the number of bits. Hence, $z_{i,k} = t_{i,k}$ and $Z_i = T_i$.

The bits output from the 1st interleaving are denoted by $d_{i,1}, d_{i,2}, d_{i,3}, \dots, d_{i,T_i}$, and $d_{i,k} = y_{i,k}$.

4.2.5.4 Relation between input and output of 1st interleaving in downlink

If fixed positions of the TrCHs in a radio frame is used then the bits input to the 1st interleaving are denoted by $h_{i1}, h_{i2}, h_{i3}, \dots, h_{iD_i}$, where i is the TrCH number. Hence, $z_{ik} = h_{ik}$ and $Z_i = D_i$.

If flexible positions of the TrCHs in a radio frame is used then the bits input to the 1st interleaving are denoted by $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$, where i is the TrCH number. Hence, $z_{ik} = g_{ik}$ and $Z_i = G_i$.

The bits output from the 1st interleaving are denoted by $q_{i1}, q_{i2}, q_{i3}, \dots, q_{iQ_i}$, where i is the TrCH number and Q_i is the number of bits. Hence, $q_{ik} = y_{ik}$, $Q_i = F_i H_i$ if fixed positions are used, and $Q_i = G_i$ if flexible positions are used.

4.2.6 Radio frame segmentation

When the transmission time interval is longer than 10 ms, the input bit sequence is segmented and mapped onto consecutive F_i radio frames. Following rate matching in the DL and radio frame size equalization in the UL the input bit sequence length is guaranteed to be an integer multiple of F_i .

The input bit sequence is denoted by $x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$ where i is the TrCH number and X_i is the number bits. The F_i output bit sequences per TTI are denoted by $y_{i,n_1}, y_{i,n_2}, y_{i,n_3}, \dots, y_{i,n_{Y_i}}$ where n_i is the radio frame number in current TTI and Y_i is the number of bits per radio frame for TrCH i . The output sequences are defined as follows:

$$y_{i,n,k} = x_{i,((n-1)Y_i)+k}, n_i = 1 \dots F_i, k = 1 \dots Y_i$$

where $Y_i = (X_i / F_i)$ is the number of bits per segment.

The n_i -th segment is mapped to the n_i -th radio frame of the transmission time interval.

4.2.6.1 Relation between input and output of the radio frame segmentation block in uplink

The input bit sequence to the radio frame segmentation is denoted by $d_{i1}, d_{i2}, d_{i3}, \dots, d_{iT_i}$, where i is the TrCH number and T_i the number of bits. Hence, $x_{ik} = d_{ik}$ and $X_i = T_i$.

The output bit sequence corresponding to radio frame n_i is denoted by $e_{i1}, e_{i2}, e_{i3}, \dots, e_{iN_i}$, where i is the TrCH number and N_i is the number of bits. Hence, $e_{i,k} = y_{i,n,k}$ and $N_i = Y_i$.

4.2.6.2 Relation between input and output of the radio frame segmentation block in downlink

The bits input to the radio frame segmentation are denoted by $q_{i1}, q_{i2}, q_{i3}, \dots, q_{iQ_i}$, where i is the TrCH number and Q_i the number of bits. Hence, $x_{ik} = q_{ik}$ and $X_i = Q_i$.

The output bit sequence corresponding to radio frame n_i is denoted by $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$, where i is the TrCH number and V_i is the number of bits. Hence, $f_{i,k} = y_{i,n,k}$ and $V_i = Y_i$.

4.2.7 Rate matching

Rate matching means that bits on a transport channel are repeated or punctured. Higher layers assign a rate-matching attribute for each transport channel. This attribute is semi-static and can only be changed through higher layer signalling. The rate-matching attribute is used when the number of bits to be repeated or punctured is calculated.

The number of bits on a transport channel can vary between different transmission time intervals. In the downlink the transmission is interrupted if the number of bits is lower than maximum. When the number of bits between different transmission time intervals in uplink is changed, bits are repeated or punctured to ensure that the total bit rate after TrCH multiplexing is identical to the total channel bit rate of the allocated dedicated physical channels.

If no bits are input to the rate matching for all TrCHs within a CCTrCH, the rate matching shall output no bits for all TrCHs within the CCTrCH and no uplink DPDCH will be selected in the case of uplink rate matching.

Notation used in clause 4.2.7

$N_{i,j}$: For uplink: Number of bits in a radio frame before rate matching on TrCH i with transport format combination j .

For downlink: An intermediate calculation variable (not an integer but a multiple of 1/8).

$N_{i,l}^{TTI}$: Number of bits in a transmission time interval before rate matching on TrCH i with transport format l .
Used in downlink only.

$\Delta N_{i,j}$: For uplink: If positive - number of bits that should be repeated in each radio frame on TrCH i with transport format combination j .

If negative - number of bits that should be punctured in each radio frame on TrCH i with transport format combination j .

For downlink: An intermediate calculation variable (not an integer but a multiple of 1/8).

$\Delta N_{i,l}^{TTI}$: If positive - number of bits to be repeated in each transmission time interval on TrCH i with transport format l .

If negative - number of bits to be punctured in each transmission time interval on TrCH i with transport format l .

Used in downlink only.

$Np_{i,l}^{TTI,m}$, $m = 0$ to $(F_{max}/F_i) - 1$:

Positive or null: number of bits to be removed in TTI number m within the largest TTI, to create the required gaps in the compressed radio frames of this TTI, in case of compressed mode by puncturing, for TrCH i with transport format l . In case of fixed positions and compressed mode by puncturing, this value is noted $Np_{i,max}^{TTI,m}$ since it is calculated for all TrCH with their maximum number of bits; thus it is the same for all TFCs.

Used in downlink only.

$Np_{i,l}^n$, $n = 0$ to $F_{max} - 1$:

Positive or null: number of bits, in radio frame number n within the largest TTI, corresponding to the gap for compressed mode in this radio frame, for TrCH i with transport format l . The value will be null for the radio frames not overlapping with a transmission gap. In case of fixed positions and compressed mode by puncturing, this value is noted $Np_{i,max}^n$ since it is calculated for all TrCHs with their maximum number of bits; thus it is the same for all TFCs.

Used in downlink only.

- $N_{TGL}[k]$, $k = 0$ to $F_{\max} - 1$:
Positive or null: number of bits in each radio frame corresponding to the gap for compressed mode for the CCTrCH.
- RM_i : Semi-static rate matching attribute for transport channel i . RM_i is provided by higher layers or takes a value as indicated in clause 4.2.13.
- PL : Puncturing limit for uplink. This value limits the amount of puncturing that can be applied in order to avoid multicode or to enable the use of a higher spreading factor. Signalled from higher layers. The allowed puncturing in % is actually equal to $(1-PL) \times 100$.
- $N_{data,j}$: Total number of bits that are available for the CCTrCH in a radio frame with transport format combination j .
- I : Number of TrCHs in the CCTrCH.
- $Z_{i,j}$: Intermediate calculation variable.
- F_i : Number of radio frames in the transmission time interval of TrCH i .
- F_{\max} Maximum number of radio frames in a transmission time interval used in the CCTrCH:

$$F_{\max} = \max_{1 \leq i \leq I} F_i$$

- n_i : Radio frame number in the transmission time interval of TrCH i ($0 \leq n_i < F_i$).
- q : Average puncturing or repetition distance (normalized to only show the remaining rate matching on top of an integer number of repetitions). Used in uplink only.
- $P1_F(n_i)$: The column permutation function of the 1st interleaver, $P1_F(x)$ is the original position of column with number x after permutation. $P1$ is defined in table 4 of clause 4.2.5.2 (note that the $P1_F$ is self-inverse). Used for rate matching in uplink only.
- $S[n]$: The shift of the puncturing or repetition pattern for radio frame n_i when $n = P1_F(n_i)$. Used in uplink only.
- $TF_i(j)$: Transport format of TrCH i for the transport format combination j .
- $TFS(i)$ The set of transport format indexes l for TrCH i .
- $TFCS$ The set of transport format combination indexes j .
- e_{ini} Initial value of variable e in the rate matching pattern determination algorithm of clause 4.2.7.5.
- e_{plus} Increment of variable e in the rate matching pattern determination algorithm of clause 4.2.7.5.
- e_{minus} Decrement of variable e in the rate matching pattern determination algorithm of clause 4.2.7.5.
- b : Indicates systematic and parity bits:
- $b = 1$: Systematic bit. x_k in clause 4.2.3.2.1.
- $b = 2$: 1st parity bit (from the upper Turbo constituent encoder). z_k in clause 4.2.3.2.1.
- $b = 3$: 2nd parity bit (from the lower Turbo constituent encoder). z'_k in clause 4.2.3.2.1.

The * (star) notation is used to replace an index x when the indexed variable X_x does not depend on the index x . In the left wing of an assignment the meaning is that " $X_* = Y$ " is equivalent to "**for all** x **do** $X_x = Y$ ". In the right wing of an assignment, the meaning is that " $Y = X_*$ " is equivalent to "**take any** x **and do** $Y = X_x$ ".

The following relations, defined for all TFC j , are used when calculating the rate matching parameters:

$$Z_{0,j} = 0$$

$$Z_{i,j} = \left\lfloor \frac{\left(\left(\sum_{m=1}^i RM_m \times N_{m,j} \right) \times N_{data,j} \right)}{\sum_{m=1}^I RM_m \times N_{m,j}} \right\rfloor \text{ for all } i = 1 \dots I \quad (1)$$

$$\Delta N_{i,j} = Z_{i,j} - Z_{i-1,j} - N_{i,j} \text{ for all } i = 1 \dots I$$

4.2.7.1 Determination of rate matching parameters in uplink

4.2.7.1.1 Determination of SF and number of PhCHs needed

In uplink, puncturing can be applied to match the CCTrCH bit rate to the PhCH bit rate. The bit rate of the PhCH(s) is limited by the UE capability and restrictions imposed by USRAN, through limitations on the PhCH spreading factor. The maximum amount of puncturing that can be applied is 1-PL, PL is signalled from higher layers. The number of available bits in the radio frames of one PhCH for all possible spreading factors is given in TS 101 851-1-3 [1]. Denote these values by N_{256} , N_{128} , N_{64} , N_{32} , N_{16} , N_8 , and N_4 , where the index refers to the spreading factor. The possible number of bits available to the CCTrCH on all PhCHs, N_{data} , then are:

$$\{ N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2 \times N_4, 3 \times N_4, 4 \times N_4, 5 \times N_4, 6 \times N_4 \}.$$

For a RACH CCTrCH SET0 represents the set of N_{data} values allowed by the USRAN, as set by the minimum SF provided by higher layers. SET0 may be a subset of $\{ N_{256}, N_{128}, N_{64}, N_{32} \}$. SET0 does not take into account the UE's capability.

For other CCTrCHs, SET0 denotes the set of N_{data} values allowed by the USRAN and supported by the UE, as part of the UE's capability. SET0 can be a subset of $\{ N_{256}, N_{128}, N_{64}, N_{32}, N_{16}, N_8, N_4, 2 \times N_4, 3 \times N_4, 4 \times N_4, 5 \times N_4, 6 \times N_4 \}$. $N_{data,j}$ for the transport format combination j is determined by executing the following algorithm:

$$\text{SET1} = \{ N_{data} \text{ in SET0 such that } \left(\min_{1 \leq y \leq I} \{ RM_y \} \right) \times N_{data} - \sum_{x=1}^I RM_x \times N_{x,j} \text{ is non negative} \}$$

If SET1 is not empty and the smallest element of SET1 requires just one PhCH then

$$N_{data,j} = \min \text{SET1}$$

else

$$\text{SET2} = \{ N_{data} \text{ in SET0 such that } \left(\min_{1 \leq y \leq I} \{ RM_y \} \right) \times N_{data} - PL \times \sum_{x=1}^I RM_x \times N_{x,j} \text{ is non negative} \}$$

sort SET2 in ascending order

$$N_{data} = \min \text{SET2}$$

while N_{data} is not the max of SET2 and the follower of N_{data} requires no additional PhCH do

$$N_{data} = \text{follower of } N_{data} \text{ in SET2}$$

end while

$$N_{data,j} = N_{data}$$

endif

For a RACH CCTrCH, if $N_{data,j}$ is not part of the UE's capability then the TFC j cannot be used.

4.2.7.1.2 Determination of parameters needed for calculating the rate matching pattern

The number of bits to be repeated or punctured, $\Delta N_{i,j}$, within one radio frame for each TrCH i is calculated with equation 1 for all possible transport format combinations j and selected every radio frame. $N_{data,j}$ is given from clause 4.2.7.1.1.

In a compressed radio frame, $N_{data,j}$ is replaced by $N_{data,j}^{cm}$ in equation 1. $N_{data,j}^{cm}$ is given as follows:

In a radio frame compressed by higher layer scheduling, $N_{data,j}^{cm}$ is obtained by executing the algorithm in clause 4.2.7.1.1 but with the number of bits in one radio frame of one PhCH reduced to $\frac{N_{tr}}{15}$ of the value in normal mode.

N_{tr} is the number of transmitted slots in a compressed radio frame and is defined by the following relation:

$$N_{tr} = \begin{cases} 15 - TGL, & \text{if } N_{first} + TGL \leq 15 \\ N_{first}, & \text{in first frame if } N_{first} + TGL > 15 \\ 30 - TGL - N_{first}, & \text{in second frame if } N_{first} + TGL > 15 \end{cases}$$

N_{first} and TGL are defined in clause 4.4.

In a radio frame compressed by spreading factor reduction, $N_{data,j}^{cm} = 2 \times (N_{data,j} - N_{TGL})$, where

$$N_{TGL} = \frac{15 - N_{tr}}{15} \times N_{data,j}$$

If $\Delta N_{i,j} = 0$ then the output data of the rate matching is the same as the input data and the rate matching algorithm of clause 4.2.7.5 does not need to be executed.

If $\Delta N_{i,j} \neq 0$ the parameters listed in clauses 4.2.7.1.2.1 and 4.2.7.1.2.2 shall be used for determining e_{ini} , e_{plus} , and e_{minus} (regardless if the radio frame is compressed or not).

4.2.7.1.3 Convolutionally encoded TrCHs

$$R = \Delta N_{i,j} \bmod N_{i,j}$$

NOTE 1: In this context $\Delta N_{i,j} \bmod N_{i,j}$ is in the range of 0 to $N_{i,j} - 1$ i.e. $-1 \bmod 10 = 9$.

if $R \neq 0$ and $2 \times R \leq N_{i,j}$

$$\text{then } q = \lceil N_{i,j} / R \rceil$$

else

$$q = \lceil N_{i,j} / (R - N_{i,j}) \rceil$$

endif

NOTE 2: q is a signed quantity.

if q is even

then $q' = q + \gcd(|q|, F_i) / F_i$ -- where $\gcd(|q|, F_i)$ means greatest common divisor of $|q|$ and F_i

NOTE 3: q' is not an integer, but a multiple of $1/8$.

else

$$q' = q$$

endif

for $x = 0$ to $F_i - 1$

$$S[\lfloor x \times q' \rfloor \bmod F_i] = (\lfloor x \times q' \rfloor \div F_i)$$

end for

$$\Delta N_i = \Delta N_{i,j}$$

$$a = 2$$

For each radio frame, the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5, where:

$$X_i = N_{i,j}, \text{ and}$$

$$e_{\text{mi}} = (a \times S[\text{P1}_{F_i}(n_i)] \times |\Delta N_i| + 1) \bmod (a \cdot N_{i,j}).$$

$$e_{\text{plus}} = a \times N_{i,j}$$

$$e_{\text{minus}} = a \times |\Delta N_i|$$

puncturing for $\Delta N < 0$, repetition otherwise.

4.2.7.1.4 Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e. $\Delta N_{i,j} > 0$, the parameters in clause 4.2.7.1.2.1 are used.

If puncturing is to be performed, the parameters below shall be used. Index b is used to indicate systematic ($b = 1$), 1st parity ($b = 2$), and 2nd parity bit ($b = 3$).

$$a = 2 \text{ when } b = 2$$

$$a = 1 \text{ when } b = 3$$

$$\Delta N_i = \begin{cases} \lfloor \Delta N_{i,j} / 2 \rfloor, & b = 2 \\ \lfloor \Delta N_{i,j} / 2 \rfloor, & b = 3 \end{cases}$$

If ΔN_i is calculated as 0 for $b = 2$ or $b = 3$, then the following procedure and the rate matching algorithm of clause 4.2.7.5 do not need to be performed for the corresponding parity bit stream.

$$X_i = \lfloor N_{i,j} / 3 \rfloor,$$

$$q = \lfloor X_i / |\Delta N_i| \rfloor$$

if ($q \leq 2$)

for $r = 0$ to $F_i - 1$

$$S[(3 \times r + b - 1) \bmod F_i] = r \bmod 2;$$

end for

else

if q is even

then $q' = q - \text{gcd}(q, F_i) / F_i$ -- where $\text{gcd}(q, F_i)$ means greatest common divisor of q and F_i
 -- note that q' is not an integer, but a multiple of $1/8$

else $q' = q$

endif

for $x = 0$ to $F_i - 1$

$$r = \lceil x \times q' \rceil \bmod F_i;$$

$$S[(3 \times r + b - 1) \bmod F_i] = \lceil x \times q' \rceil \text{div } F_i;$$

end for

endif

For each radio frame, the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5, where:

X_i is as above:

$$e_{\text{ini}} = (a \times S[\text{PI}_{F_i}(n_i)] \times |\Delta N_i| + X_i) \bmod (a \times X_i), \text{ if } e_{\text{ini}} = 0 \text{ then } e_{\text{ini}} = a \times X_i$$

$$e_{\text{plus}} = a \times X_i$$

$$e_{\text{minus}} = a \times |\Delta N_i|$$

4.2.7.2 Determination of rate matching parameters in downlink

$N_{\text{data},j}$ does not depend on the transport format combination j . $N_{\text{data},*}$ is given by the channelization code(s) assigned by higher layers.

Denote the number of physical channels used for the CCTrCH by P . $N_{\text{data},*}$ is the number of bits available to the CCTrCH in one radio frame and defined as $N_{\text{data},*} = P \times 15 \times (N_{\text{data}1} + N_{\text{data}2})$, where $N_{\text{data}1}$ and $N_{\text{data}2}$ are defined in TS 101 851-1-3 [1]. Note that contrary to the uplink, the same rate matching patterns are used in TTIs containing no compressed radio frames and in TTIs containing radio frames compressed by spreading factor reduction or higher layer scheduling.

In the following, the total amount of puncturing or repetition for the TTI is calculated.

Additional calculations for TTIs containing radio frames compressed by puncturing in case fixed positions are used, are performed to determine this total amount of rate matching needed.

For compressed mode by puncturing, in TTIs where some compressed radio frames occur, the puncturing is increased or the repetition is decreased compared to what is calculated according to the rate matching parameters provided by higher layers. This allows to cope with reduction of available data bits on the physical channel(s) if the slot format for the compressed frame(s) contains fewer data bits than for the normal frames(s), and to create room for later insertion of marked bits, noted p-bits, which will identify the positions of the gaps in the compressed radio frames.

The amount of additional puncturing corresponds to the number of bits to create the gap in the TTI for TrCH i , plus the difference between the number of data bits available in normal frames and in compressed frames, due to slot format change. In case of fixed positions, it is calculated in addition to the amount of rate matching indicated by higher layers.

It is noted $Np_{i,\text{max}}^{\text{TTI},m}$.

In fixed positions case, to obtain the total rate matching $\Delta N_{i,\max}^{TTI,cm,m}$ to be performed on the TTI m , $Np_{i,\max}^{TTI,m}$ is subtracted from $\Delta N_{i,\max}^{TTI,m}$ (calculated based on higher layers RM parameters as for normal rate matching). This allows to create room for the $Np_{i,\max}^{TTI,m}$ bits p to be inserted later. If the result is null, i.e. the amount of repetition matches exactly the amount of additional puncturing needed, then no rate matching is necessary.

In case of compressed mode by puncturing and fixed positions, for some calculations, $N'_{data,*}$ is used for radio frames with gap instead of $N_{data,*}$, where $N'_{data,*} = P \times 15 \times (N'_{data1} + N'_{data2})$. N'_{data1} and N'_{data2} are the number of bits in the data fields of the slot format used for the frames compressed by puncturing.

4.2.7.2.1 Determination of rate matching parameters for fixed positions of TrCHs

4.2.7.2.1.1 Calculation of $\Delta N_{i,\max}$ for normal mode and compressed mode by spreading factor reduction

First an intermediate calculation variable $N_{i,*}$ is calculated for all transport channels i by the following formula:

$$N_{i,*} = \frac{1}{F_i} \times \left(\max_{l \in TFS(i)} N_{i,l}^{TTI} \right)$$

In order to compute the $\Delta N_{i,l}^{TTI}$ parameters for all TrCH i and all TF l , we first compute an intermediate parameter $\Delta N_{i,\max}$ by the following formula, where $\Delta N_{i,*}$ is derived from $N_{i,*}$ by the formula given at clause 4.2.7:

$$\Delta N_{i,\max} = F_i \times \Delta N_{i,*}$$

If $\Delta N_{i,\max} = 0$ then, for TrCH i , the output data of the rate matching is the same as the input data and the rate matching algorithm of clause 4.2.7.5 does not need to be executed. In this case we have:

$$\forall l \in TFS(i) \Delta N_{i,l}^{TTI} = 0$$

If $\Delta N_{i,\max} \neq 0$ the parameters listed in clauses 4.2.7.2.1.3 and 4.2.7.2.1.4 shall be used for determining e_{ini} , e_{plus} and e_{minus} and $\Delta N_{i,l}^{TTI}$.

4.2.7.2.1.2 Calculations for compressed mode by puncturing

Calculations of $\Delta N_{i,\max}^{TTI,m}$ for all TTI m within largest TTI, for all TrCH i .

First an intermediate calculation variable $N_{i,*}$ is calculated for all transport channels i by the following formula:

$$N_{i,*} = \frac{1}{F_i} \times \left(\max_{l \in TFS(i)} N_{i,l}^{TTI} \right)$$

Then an intermediate calculation variable $\Delta N_{i,*}$ is derived from $N_{i,*}$ by the formula given at clause 4.2.7, for all TrCH i .

In order to compute the $\Delta N_{i,l}^{TTI,m}$ parameters for all TrCH i , all TF l and all TTI with number m in the largest TTI, we first compute an intermediate parameter $\Delta N_{i,\max}^m$ by the following formula:

$$\Delta N_{i,\max}^m = F_i \times \Delta N_{i,*}$$

Calculations of $Np_{i,\max}^n$ and $Np_{i,\max}^{TTI,m}$

Let $Np_{i,\max}^n$ be the number of bits to eliminate on TrCH i to create the gap for compressed mode and to cope for the reduction of the number of available data bits in the compressed frame if the changed slot format contains fewer data bits than for normal frame, in each radio frame n of the TTI, calculated for the Transport Format Combination of TrCH i , in which the number of bits of TrCH i is at its maximum.

$Np_{i,\max}^n$ is calculated for each radio frame n of the TTI in the following way.

Intermediate variables Z_i for $i = 1$ to I are calculated using the formula (1) in clause 4.2.7, by replacing $N_{data,j}$ in the frames compressed by puncturing with $(N_{TGL}[n] + (N_{data,*} - N'_{data,*}))$.

The number of bits corresponding to the gap for TrCH i , in each radio frame of its TTI is calculated using the number of bits to remove on all Physical Channels $N_{TGL}[k]$, where k is the radio frame number in the largest TTI.

For each radio frame k of the largest TTI that is overlapping with a transmission gap, $N_{TGL}[k]$ is given by the relation:

$$N_{TGL} = \begin{cases} \frac{TGL}{15} \times N'_{data,*} & , \text{ if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} \times N'_{data,*} & , \text{ in first radio frame of the gap if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} \times N'_{data,*} & , \text{ in second radio frame of the gap if } N_{first} + TGL > 15 \end{cases}$$

N_{first} and TGL are defined in clause 4.4.

Note that $N_{TGL}[k] = 0$ if radio frame k is not overlapping with a transmission gap.

Then $Np_{i,\max}^n = (Z_i - Z_{i-1})$ for $i = 1$ to I .

The total number of bits $Np_{i,\max}^{TTI,m}$ corresponding to the gaps for compressed mode for TrCH i in the TTI is calculated as:

$$Np_{i,\max}^{TTI,m} = \sum_{n=m \times F_i}^{n=(m+1) \times F_i - 1} Np_{i,\max}^n$$

The amount of rate matching $\Delta N_{i,\max}^{TTI,cm,m}$ for the highest TrCH bit rate is then computed by the following formula:

$$\Delta N_{i,\max}^{TTI,cm,m} = \Delta N_{i,\max}^m - Np_{i,\max}^{TTI,m}$$

If $\Delta N_{i,\max}^{TTI,cm,m} = 0$, then, for TrCH i , the output data of the rate matching is the same as the input data and the rate matching algorithm of clause 4.2.7.5 does not need to be executed.

If $\Delta N_{i,\max}^{TTI,cm,m} \neq 0$, then, for TrCH i , the rate matching algorithm of clause 4.2.7.5 needs to be executed, and the parameters listed in clauses 4.2.7.2.1.3 and 4.2.7.2.1.4 shall be used for determining e_{ini} , e_{plus} , and e_{minus} and $\Delta N_{i,l}^{TTI,m}$.

4.2.7.2.1.3 Determination of rate matching parameters for convolutionally encoded TrCHs

$$\Delta N_i = \Delta N_{i,max}$$

For compressed mode by puncturing, ΔN_i is defined as: $\Delta N_i = \Delta N_{i,max}^{TTI,cm,m}$, instead of the previous relation.

$$a = 2$$

$$N_{max} = \max_{l \in TFS(i)} N_{il}^{TTI}$$

For each transmission time interval of TrCH i with TF l , the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI}$$

$$e_{ini} = 1$$

$$e_{plus} = a \times N_{max}$$

$$e_{minus} = a \times |\Delta N_i|$$

Puncturing if $\Delta N_i < 0$, repetition otherwise. The values of $\Delta N_{i,l}^{TTI}$ may be computed by counting repetitions or puncturing when the algorithm of clause 4.2.7.5 is run. The resulting values of $\Delta N_{i,l}^{TTI}$ can be represented with following expression.

$$\Delta N_{i,l}^{TTI} = \left\lceil \frac{|\Delta N_i| \times X_i}{N_{max}} \right\rceil \times \text{sgn}(\Delta N_i)$$

For compressed mode by puncturing, the above formula produces $\Delta N_{i,l}^{TTI,m}$ instead of $\Delta N_{i,l}^{TTI}$.

4.2.7.2.1.4 Determination of rate matching parameters for Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e. $\Delta N_{i,max} > 0$, the parameters in clause 4.2.7.2.1.3 are used.

If puncturing is to be performed, the parameters below shall be used. Index b is used to indicate systematic ($b = 1$), 1st parity ($b = 2$), and 2nd parity bit ($b = 3$).

$$a = 2 \text{ when } b = 2$$

$$a = 1 \text{ when } b = 3$$

The bits indicated by $b = 1$ shall not be punctured.

$$\Delta N_i^b = \begin{cases} \left\lfloor \frac{\Delta N_{i,max}}{2} \right\rfloor, & \text{for } b = 2 \\ \left\lceil \frac{\Delta N_{i,max}}{2} \right\rceil, & \text{for } b = 3 \end{cases}$$

In Compressed Mode by puncturing, the following relations are used instead of the previous ones:

$$\Delta N_i^b = \left\lfloor \frac{\Delta N_{i,max}^{TTI,cm,m}}{2} \right\rfloor, \text{ for } b = 2$$

$$\Delta N_i^b = \left\lceil \frac{\Delta N_{i,max}^{TTI,cm,m}}{2} \right\rceil, \text{ for } b = 3$$

$$N_{max} = \max_{l \in TFS(i)} (N_{il}^{TTI} / 3)$$

For each transmission time interval of TrCH i with TF l , the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI} / 3$$

$$e_{ini} = N_{max}$$

$$e_{plus} = a \times N_{max}$$

$$e_{minus} = a \times \left| \Delta N_i^b \right|$$

The values of $\Delta N_{i,l}^{TTI}$ may be computed by counting puncturing when the algorithm of clause 4.2.7.5 is run. The resulting values of $\Delta N_{i,l}^{TTI}$ can be represented with following expression.

$$\Delta N_{i,l}^{TTI} = - \left[\frac{\left| \Delta N_i^2 \right| \times X_i}{N_{max}} + 0.5 \right] - \left[\frac{\left| \Delta N_i^3 \right| \times X_i}{N_{max}} \right]$$

In the above equation, the first term of the right hand side represents the amount of puncturing for $b = 2$ and the second term represents the amount of puncturing for $b = 3$.

For compressed mode by puncturing, the above formula produces $\Delta N_{i,l}^{TTI,m}$ instead of $\Delta N_{i,l}^{TTI}$.

4.2.7.2.2 Determination of rate matching parameters for flexible positions of TrCHs

4.2.7.2.2.1 Calculations for normal mode, compressed mode by higher layer scheduling, and compressed mode by spreading factor reduction

First an intermediate calculation variable N_{ij} is calculated for all transport channels i and all transport format combinations j by the following formula:

$$N_{i,j} = \frac{1}{F_i} \times N_{i,TF_i(j)}^{TTI}$$

Then rate matching ratios RF_i are calculated for each the transport channel i in order to minimize the number of DTX bits when the bit rate of the CCTrCH is maximum. The RF_i ratios are defined by the following formula:

$$RF_i = \frac{N_{data,*}}{\max_{j \in TFCs} \sum_{i=1}^{i=l} (RM_i \times N_{i,j})} \times RM_i$$

The computation of $\Delta N_{i,l}^{TTI}$ parameters is then performed in two phases. In a first phase, tentative temporary values of $\Delta N_{i,l}^{TTI}$ are computed, and in the second phase they are checked and corrected. The first phase, by use of the RF_i ratios, ensures that the number of DTX indication bits inserted is minimum when the CCTrCH bit rate is maximum, but it does not ensure that the maximum CCTrCH bit rate is not greater than $N_{data,*}$ per 10 ms. The latter condition is ensured through the checking and possible corrections carried out in the second phase.

At the end of the second phase, the latest value of $\Delta N_{i,l}^{TTI}$ is the definitive value.

The first phase defines the tentative temporary $\Delta N_{i,l}^{TTI}$ for all transport channel i and any of its transport format l by use of the following formula:

$$\Delta N_{i,l}^{TTI} = F_i \times \left\lceil \frac{RF_i \times N_{i,l}^{TTI}}{F_i} \right\rceil - N_{i,l}^{TTI} = F_i \times \left\lceil \frac{N_{data,*} \times RM_i \times N_{i,l}^{TTI}}{F_i \times \max_{j \in TFCS} \sum_{i=1}^I (RM_i \times N_{i,j})} \right\rceil - N_{i,l}^{TTI}$$

The second phase is defined by the following algorithm:

for all j in $TFCS$ in ascending order of TFCI do -- for all TFC

$$D = \sum_{i=1}^{I} \frac{N_{i,TF_i(j)}^{TTI} + \Delta N_{i,TF_i(j)}^{TTI}}{F_i} \quad \text{-- CCTrCH bit rate (bits per 10 ms) for TFC } j$$

if $D > N_{data,*}$ then

for $i = 1$ to I do -- for all TrCH

$$\Delta N = F_i \times \Delta N_{i,j} \quad \text{-- } \Delta N_{i,j} \text{ is derived from } N_{i,j} \text{ by the formula given at clause 4.2.7.}$$

if $\Delta N_{i,TF_i(j)}^{TTI} > \Delta N$ then

$$\Delta N_{i,TF_i(j)}^{TTI} = \Delta N$$

end-if

end-for

end-if

end-for

If $\Delta N_{i,l}^{TTI} = 0$ then, for TrCH i at TF l , the output data of the rate matching is the same as the input data and the rate matching algorithm of clause 4.2.7.5 does not need to be executed.

If $\Delta N_{i,l}^{TTI} \neq 0$ the parameters listed in clauses 4.2.7.2.2.2 and 4.2.7.2.2.3 shall be used for determining e_{ini} , e_{plus} , and e_{minus} .

4.2.7.2.2.2 Determination of rate matching parameters for convolutionally encoded TrCHs

$$\Delta N_i = \Delta N_{il}^{TTI}$$

$$a = 2$$

For each transmission time interval of TrCH i with TF l , the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI}$$

$$e_{ini} = 1$$

$$e_{plus} = a \times N_{il}^{TTI}$$

$$e_{minus} = a \times |\Delta N_i|$$

puncturing for $\Delta N_i < 0$, repetition otherwise.

4.2.7.2.2.3 Determination of rate matching parameters for Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs, i.e. $\Delta N_{il}^{TTI} > 0$, the parameters in clause 4.2.7.2.2 are used.

If puncturing is to be performed, the parameters below shall be used. Index b is used to indicate systematic ($b = 1$), 1st parity ($b = 2$), and 2nd parity bit ($b = 3$).

$$a = 2 \text{ when } b = 2$$

$$a = 1 \text{ when } b = 3$$

The bits indicated by $b = 1$ shall not be punctured.

$$\Delta N_i = \begin{cases} \left\lfloor \frac{\Delta N_{il}^{TTI}}{2} \right\rfloor, & b = 2 \\ \left\lfloor \frac{\Delta N_{il}^{TTI}}{2} \right\rfloor, & b = 3 \end{cases}$$

For each transmission time interval of TrCH i with TF l , the rate-matching pattern is calculated with the algorithm in clause 4.2.7.5. The following parameters are used as input:

$$X_i = N_{il}^{TTI} / 3,$$

$$e_{ini} = X_i,$$

$$e_{plus} = a \times X_i$$

$$e_{minus} = a \times |\Delta N_i|$$

4.2.7.3 Bit separation and collection in uplink

The systematic bits of turbo encoded TrCHs shall not be punctured, the other bits may be punctured. The systematic bits, first parity bits, and second parity bits in the bit sequence input to the rate matching block are therefore separated into three sequences.

The first sequence contains:

- All of the systematic bits that are from turbo encoded TrCHs.
- From 0 to 2 first and/or second parity bits that are from turbo encoded TrCHs. These bits come into the first sequence when the total number of bits in a block after radio frame segmentation is not a multiple of three.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

The second sequence contains:

- All of the first parity bits that are from turbo encoded TrCHs, except those that go into the first sequence when the total number of bits is not a multiple of three.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

The third sequence contains:

- All of the second parity bits that are from turbo encoded TrCHs, except those that go into the first sequence when the total number of bits is not a multiple of three.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

The second and third sequences shall be of equal length, whereas the first sequence can contain from 0 to 2 more bits. Puncturing is applied only to the second and third sequences. The bit separation function is transparent for convolutionally encoded TrCHs and for turbo encoded TrCHs with repetition. The bit separation and bit collection are illustrated in figures 5 and 6.

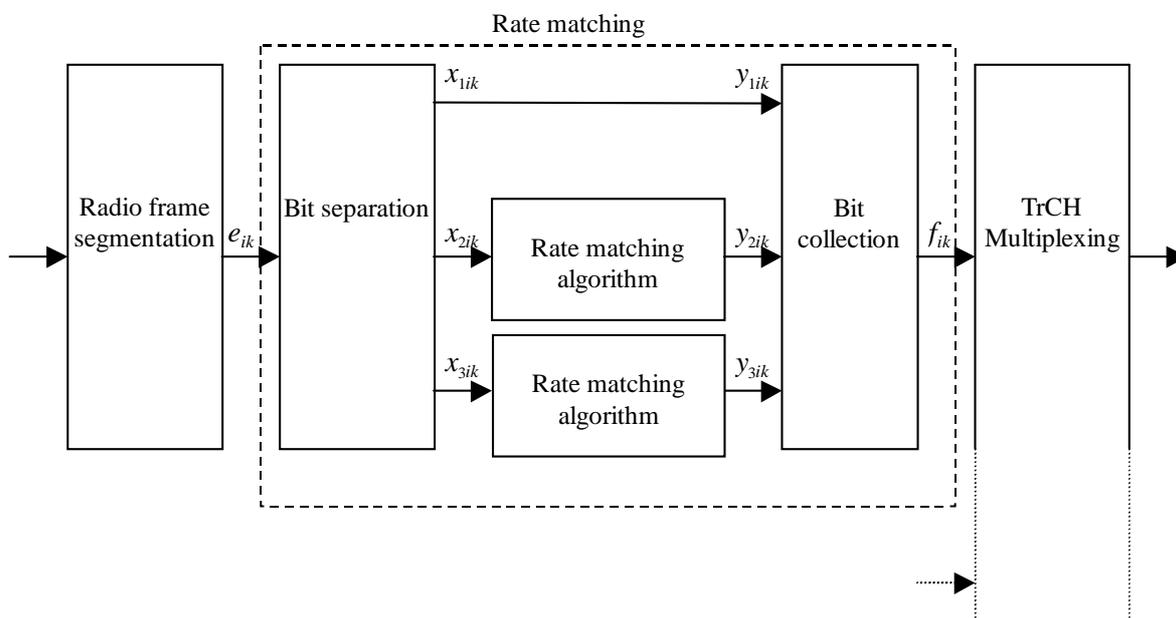

Figure 5: Puncturing of turbo encoded TrCHs in uplink

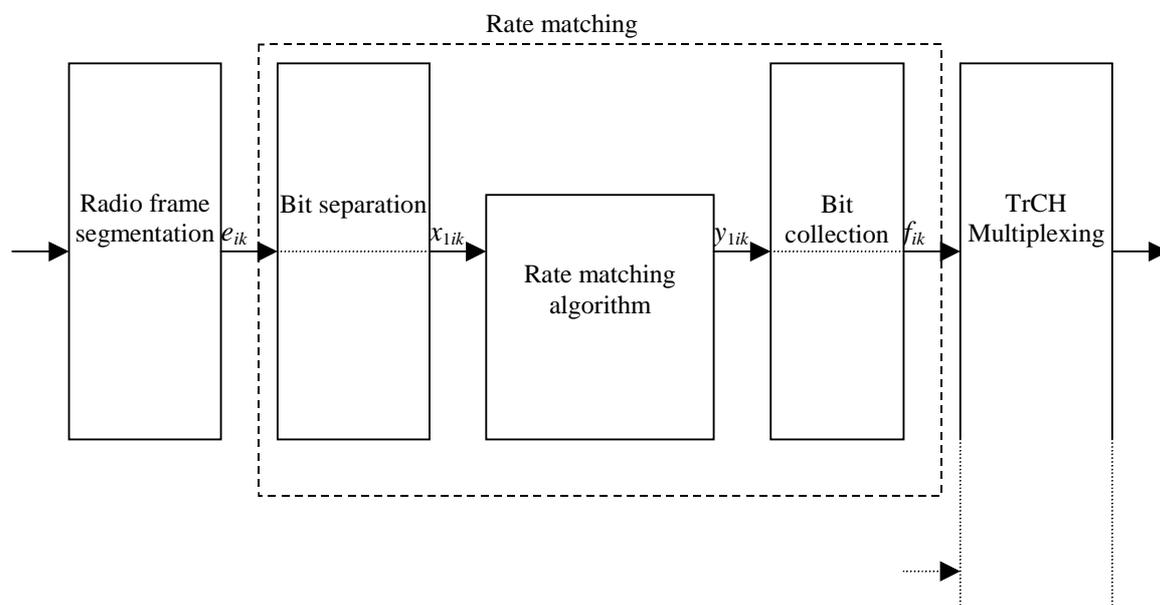

Figure 6: Rate matching for convolutionally encoded TrCHs and for turbo encoded TrCHs with repetition in uplink

The bit separation is dependent on the 1st interleaving and offsets are used to define the separation for different TTIs. b indicates the three sequences defined in this clause, with $b = 1$ indicating the first sequence, $b = 2$ the second one, and $b = 3$ the third one. The offsets α_b for these sequences are listed in table 5.

Table 5: TTI dependent offset needed for bit separation

TTI (ms)	α_1	α_2	α_3
10, 40	0	1	2
20, 80	0	2	1

The bit separation is different for different radio frames in the TTI. A second offset is therefore needed. The radio frame number for TrCH i is denoted by n_i , and the offset by β_{n_i} .

Table 6: Radio frame dependent offset needed for bit separation

TTI (ms)	β_0	β_1	β_2	β_3	β_4	β_5	β_6	β_7
10	0	NA						
20	0	1	NA	NA	NA	NA	NA	NA
40	0	1	2	0	NA	NA	NA	NA
80	0	1	2	0	1	2	0	1

4.2.7.3.1 Bit separation

The bits input to the rate matching are denoted by $e_{i1}, e_{i2}, e_{i3}, \dots, e_{iN_i}$, where i is the TrCH number and N_i is the number of bits input to the rate matching block. Note that the transport format combination number j for simplicity has been left out in the bit numbering, i.e. $N_i = N_{ij}$. The bits after separation are denoted by $x_{bi1}, x_{bi2}, x_{bi3}, \dots, x_{biX_i}$. For turbo encoded TrCHs with puncturing, b indicates the three sequences defined in clause 4.2.7.3, with $b = 1$ indicating the first sequence, and so forth. For all other cases b is defined to be 1. X_i is the number of bits in each separated bit sequence. The relation between e_{ik} and x_{bik} is given below.

For turbo encoded TrCHs with puncturing:

$$x_{1,i,k} = e_{i,3(k-1)+1+(\alpha_1+\beta_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i/3 \rfloor$$

$$x_{1,i,\lfloor N_i/3 \rfloor+k} = e_{i,3\lfloor N_i/3 \rfloor+k} \quad k = 1, \dots, N_i \bmod 3$$

NOTE: When $(N_i \bmod 3) = 0$ this row is not needed.

$$x_{2,i,k} = e_{i,3(k-1)+1+(\alpha_2+\beta_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i/3 \rfloor$$

$$x_{3,i,k} = e_{i,3(k-1)+1+(\alpha_3+\beta_{n_i}) \bmod 3} \quad k = 1, 2, 3, \dots, X_i \quad X_i = \lfloor N_i/3 \rfloor$$

For convolutionally encoded TrCHs and turbo encoded TrCHs with repetition:

$$x_{1,i,k} = e_{i,k} \quad k = 1, 2, 3, \dots, X_i \quad X_i = N_i$$

4.2.7.3.2 Bit collection

The bits x_{bik} are input to the rate matching algorithm described in clause 4.2.7.5. The bits output from the rate matching algorithm are denoted $y_{bi1}, y_{bi2}, y_{bi3}, \dots, y_{biY_i}$.

Bit collection is the inverse function of the separation. The bits after collection are denoted by $z_{bi1}, z_{bi2}, z_{bi3}, \dots, z_{biY_i}$. After bit collection, the bits indicated as punctured are removed and the bits are then denoted by $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$, where i is the TrCH number and $V_i = N_{ij} + \Delta N_{ij}$. The relations between y_{bik} , z_{bik} , and f_{ik} are given below.

For turbo encoded TrCHs with puncturing ($Y_i = X_i$):

$$z_{i,3(k-1)+1+(\alpha_1+\beta_{n_i}) \bmod 3} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3\lfloor N_i/3 \rfloor+k} = y_{1,i,\lfloor N_i/3 \rfloor+k} \quad k = 1, \dots, N_i \bmod 3$$

NOTE: When $(N_i \bmod 3) = 0$ this row is not needed.

$$z_{i,3(k-1)+1+(\alpha_2+\beta_{n_i}) \bmod 3} = y_{2,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

$$z_{i,3(k-1)+1+(\alpha_3+\beta_{n_i}) \bmod 3} = y_{3,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

After the bit collection, bits $z_{i,k}$ with value δ , where $\delta \notin \{0, 1\}$, are removed from the bit sequence. Bit $f_{i,1}$ corresponds to the bit $z_{i,k}$ with smallest index k after puncturing, bit $f_{i,2}$ corresponds to the bit $z_{i,k}$ with second smallest index k after puncturing, and so on.

For convolutionally encoded TrCHs and turbo encoded TrCHs with repetition:

$$z_{i,k} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

When repetition is used, $f_{i,k} = z_{i,k}$ and $Y_i = V_i$.

When puncturing is used, $Y_i = X_i$ and bits $z_{i,k}$ with value δ , where $\delta \notin \{0, 1\}$, are removed from the bit sequence. Bit $f_{i,1}$ corresponds to the bit $z_{i,k}$ with smallest index k after puncturing, bit $f_{i,2}$ corresponds to the bit $z_{i,k}$ with second smallest index k after puncturing, and so on.

4.2.7.4 Bit separation and collection in downlink

The systematic bits of turbo encoded TrCHs shall not be punctured, the other bits may be punctured.

The systematic bits, first parity bits and second parity bits in the bit sequence input to the rate matching block are therefore separated into three sequences of equal lengths.

The first sequence contains:

- All of the systematic bits that are from turbo encoded TrCHs.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

The second sequence contains:

- All of the first parity bits that are from turbo encoded TrCHs.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

The third sequence contains:

- All of the second parity bits that are from turbo encoded TrCHs.
- Some of the systematic, first parity and second parity bits that are for trellis termination.

Puncturing is applied only to the second and third sequences.

The bit separation function is transparent for convolutionally encoded TrCHs and for turbo encoded TrCHs with repetition. The bit separation and bit collection are illustrated in figures 7 and 8.

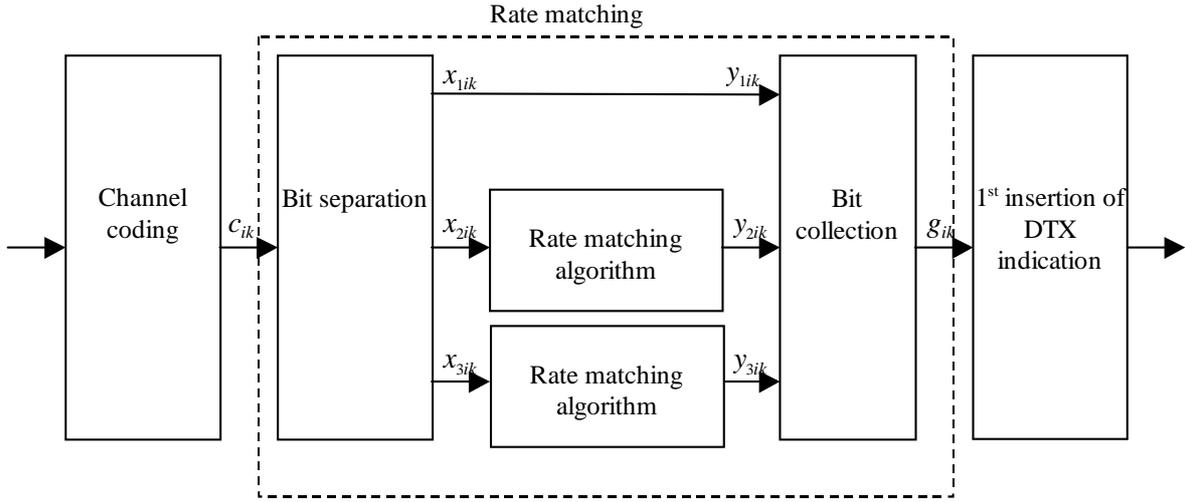

Figure 7: Puncturing of turbo encoded TrCHs in downlink

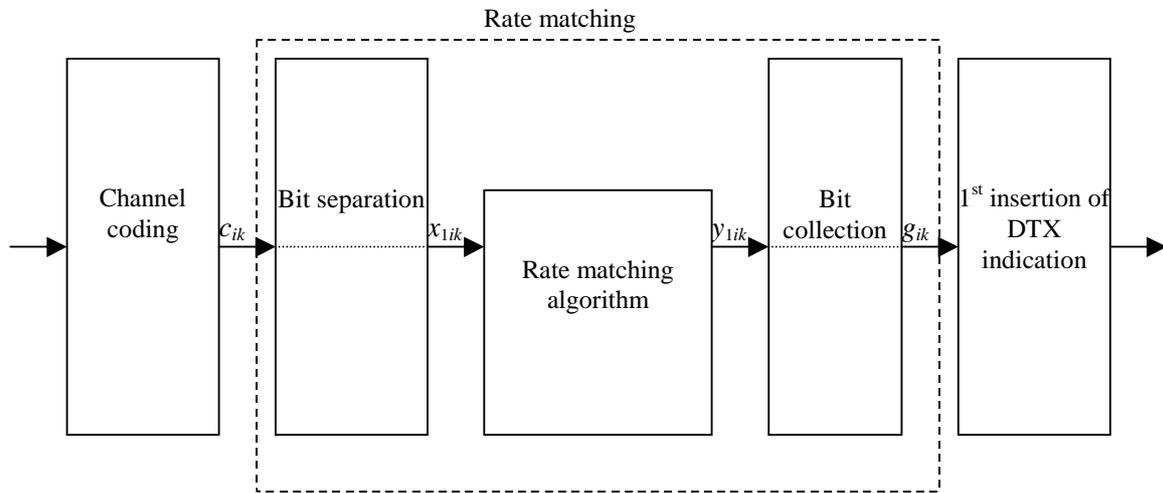

Figure 8: Rate matching for convolutionally encoded TrCHs and for turbo encoded TrCHs with repetition in downlink

4.2.7.4.1 Bit separation

The bits input to the rate matching are denoted by $c_{i1}, c_{i2}, c_{i3}, \dots, c_{iE_i}$, where i is the TrCH number and E_i is the number of bits input to the rate matching block. Note that E_i is a multiple of 3 for turbo encoded TrCHs and that the transport format l for simplicity has been left out in the bit numbering, i.e. $E_i = N_{il}^{TTI}$. The bits after separation are denoted by $x_{bi1}, x_{bi2}, x_{bi3}, \dots, x_{biX_i}$. For turbo encoded TrCHs with puncturing, b indicates the three sequences defined in clause 4.2.7.4, with $b = 1$ indicating the first sequence, and so forth. For all other cases b is defined to be 1. X_i is the number of bits in each separated bit sequence. The relation between c_{ik} and x_{bik} is given below.

For turbo encoded TrCHs with puncturing:

$$\begin{aligned} x_{1,i,k} &= c_{i,3(k-1)+1} & k &= 1, 2, 3, \dots, X_i & X_i &= E_i/3 \\ x_{2,i,k} &= c_{i,3(k-1)+2} & k &= 1, 2, 3, \dots, X_i & X_i &= E_i/3 \\ x_{3,i,k} &= c_{i,3(k-1)+3} & k &= 1, 2, 3, \dots, X_i & X_i &= E_i/3 \end{aligned}$$

For convolutionally encoded TrCHs and turbo encoded TrCHs with repetition:

$$x_{1,i,k} = c_{i,k} \quad k = 1, 2, 3, \dots, X_i \quad X_i = E_i$$

4.2.7.4.2 Bit collection

The bits x_{bik} are input to the rate matching algorithm described in clause 4.2.7.5. The bits output from the rate matching algorithm are denoted $y_{bi1}, y_{bi2}, y_{bi3}, \dots, y_{biY_i}$.

Bit collection is the inverse function of the separation. The bits after collection are denoted by $z_{bi1}, z_{bi2}, z_{bi3}, \dots, z_{biY_i}$. After bit collection, the bits indicated as punctured are removed and the bits are then denoted by $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$, where i is the TrCH number and $G_i = N_{il}^{TTI} + \Delta N_{il}^{TTI}$. The relations between y_{bik} , z_{bik} , and g_{ik} are given below.

For turbo encoded TrCHs with puncturing ($Y_i = X_i$):

$$\begin{aligned} z_{i,3(k-1)+1} &= y_{1,i,k} & k &= 1, 2, 3, \dots, Y_i \\ z_{i,3(k-1)+2} &= y_{2,i,k} & k &= 1, 2, 3, \dots, Y_i \\ z_{i,3(k-1)+3} &= y_{3,i,k} & k &= 1, 2, 3, \dots, Y_i \end{aligned}$$

After the bit collection, bits $z_{i,k}$ with value δ , where $\delta \notin \{0, 1\}$, are removed from the bit sequence. Bit $g_{i,1}$ corresponds to the bit $z_{i,k}$ with smallest index k after puncturing, bit $g_{i,2}$ corresponds to the bit $z_{i,k}$ with second smallest index k after puncturing, and so on.

For convolutionally encoded TrCHs and turbo encoded TrCHs with repetition:

$$z_{i,k} = y_{1,i,k} \quad k = 1, 2, 3, \dots, Y_i$$

When repetition is used, $g_{i,k} = z_{i,k}$ and $Y_i = G_i$.

When puncturing is used, $Y_i = X_i$ and bits $z_{i,k}$ with value δ , where $\delta \notin \{0, 1\}$, are removed from the bit sequence. Bit $g_{i,1}$ corresponds to the bit $z_{i,k}$ with smallest index k after puncturing, bit $g_{i,2}$ corresponds to the bit $z_{i,k}$ with second smallest index k after puncturing, and so on.

4.2.7.5 Rate matching pattern determination

Denote the bits before rate matching by:

$x_{i1}, x_{i2}, x_{i3}, \dots, x_{iX_i}$, where i is the TrCH number and the sequence is defined in clause 4.2.7.3 for uplink or in clause 4.2.7.4 for downlink. Parameters X_i , e_{ini} , e_{plus} , and e_{minus} are given in clause 4.2.7.1 for uplink or in clause 4.2.7.2 for downlink.

The rate matching rule is as follows:

if puncturing is to be performed

$e = e_{ini}$ -- initial error between current and desired puncturing ratio

$m = 1$ -- index of current bit

do while $m \leq X_i$

$e = e - e_{minus}$ -- update error

```

if e ≤ 0 then      -- check if bit number m should be punctured
    set bit  $x_{i,m}$  to  $\delta$  where  $\delta \in \{0, 1\}$ 
    e = e + eplus  -- update error
endif
m = m + 1        -- next bit
end do
else
e = eini        -- initial error between current and desired puncturing ratio
m = 1           -- index of current bit
do while m ≤ Xi
    e = e - eminus  -- update error
    do while e ≤ 0  -- check if bit number m should be repeated
        repeat bit  $x_{i,m}$ 
        e = e + eplus  -- update error
    end do
    m = m + 1      -- next bit
end do
endif

```

A repeated bit is placed directly after the original one.

4.2.8 TrCH multiplexing

Every 10 ms, one radio frame from each TrCH is delivered to the TrCH multiplexing. These radio frames are serially multiplexed into a coded composite transport channel (CCTrCH).

The bits input to the TrCH multiplexing are denoted by $f_{i1}, f_{i2}, f_{i3}, \dots, f_{iV_i}$, where i is the TrCH number and V_i is the number of bits in the radio frame of TrCH i . The number of TrCHs is denoted by I . The bits output from TrCH multiplexing are denoted by $s_1, s_2, s_3, \dots, s_S$, where S is the number of bits, i.e. $S = \sum_i V_i$. The TrCH multiplexing is defined by the following relations:

$$s_k = f_{1k} \quad k = 1, 2, \dots, V_1$$

$$s_k = f_{2,(k-V_1)} \quad k = V_1 + 1, V_1 + 2, \dots, V_1 + V_2$$

$$s_k = f_{3,(k-(V_1+V_2))} \quad k = (V_1 + V_2) + 1, (V_1 + V_2) + 2, \dots, (V_1 + V_2) + V_3$$

...

$$s_k = f_{I,(k-(V_1+V_2+\dots+V_{I-1}))} \quad k = (V_1 + V_2 + \dots + V_{I-1}) + 1, (V_1 + V_2 + \dots + V_{I-1}) + 2, \dots, (V_1 + V_2 + \dots + V_{I-1}) + V_I$$

4.2.9 Insertion of discontinuous transmission (DTX) indication bits

In the downlink, DTX is used to fill up the radio frame with bits. The insertion point of DTX indication bits depends on whether fixed or flexible positions of the TrCHs in the radio frame are used. It is up to the USRAN to decide for each CCTrCH whether fixed or flexible positions are used during the connection. DTX indication bits only indicate when the transmission should be turned off, they are not transmitted.

4.2.9.1 1st insertion of DTX indication bits

This step of inserting DTX indication bits is used only if the positions of the TrCHs in the radio frame are fixed. With fixed position scheme a fixed number of bits is reserved for each TrCH in the radio frame.

The bits from rate matching are denoted by $g_{i1}, g_{i2}, g_{i3}, \dots, g_{iG_i}$, where G_i is the number of bits in one TTI of TrCH i . Denote the number of bits in one radio frame of TrCH i by H_i . Denote D_i the number of bits output of the first DTX insertion block.

In TTIs containing no compressed frames or frames compressed by spreading factor reduction, H_i is constant and corresponds to the maximum number of bits from TrCH i in one radio frame for any transport format of TrCH i and $D_i = F_i \times H_i$.

In TTIs containing frames compressed by puncturing, additional puncturing is performed in the rate matching block. The empty positions resulting from the additional puncturing are used to insert p-bits in the first interleaving block, the DTX insertion is therefore limited to allow for later insertion of p-bits. Thus DTX bits are inserted until the total number of bits is D_i where $D_i = F_i \times H_i - Np^{TTI, m_{i,max}}$ and $H_i = N_{i,*} + \Delta N_{i,*}$.

The bits output from the DTX insertion is denoted by $h_{i1}, h_{i2}, h_{i3}, \dots, h_{iD_i}$. Note that these bits are three valued. They are defined by the following relations:

$$\begin{aligned} h_{ik} &= g_{ik} & k &= 1, 2, 3, \dots, G_i \\ h_{ik} &= \delta & k &= G_i + 1, G_i + 2, G_i + 3, \dots, D_i \end{aligned}$$

where DTX indication bits are denoted by δ . Here $g_{ik} \in \{0, 1\}$ and $\delta \notin \{0, 1\}$.

4.2.9.2 2nd insertion of DTX indication bits

The DTX indication bits inserted in this step shall be placed at the end of the radio frame. Note that the DTX will be distributed over all slots after 2nd interleaving.

The bits input to the DTX insertion block are denoted by $s_1, s_2, s_3, \dots, s_S$, where S is the number of bits from TrCH multiplexing. The number of PhCHs is denoted by P and the number of bits in one radio frame, including DTX indication bits, for each PhCH by R .

In non-compressed frames, $R = \frac{N_{data,*}}{P} = 15 \times (N_{data1} + N_{data2})$, where N_{data1} and N_{data2} are defined in TS 101 851-1-3 [1].

For compressed frames, $N'_{data,*}$ is defined as $N'_{data,*} = P \times 15 \times (N'_{data1} + N'_{data2})$. N'_{data1} and N'_{data2} are the number of bits in the data fields of the slot format used for the current compressed frame, i.e. slot format A or B as defined in TS 101 851-1-3 [1] corresponding to the spreading factor and the number of transmitted slots in use.

In frames compressed by puncturing and when fixed positions are used, no DTX shall be inserted, since the exact room for the gap is already reserved thanks to the earlier insertion of the p-bits.

In frames compressed by higher layer scheduling, additional DTX with respect to normal mode shall be inserted if the transmission time reduction does not exactly create a transmission gap of the desired TGL .

The number of bits available to the CCTrCH in one radio frame compressed by spreading factor reduction or by higher layer scheduling is denoted by $N_{data,*}^{cm}$ and $R = \frac{N_{data,*}^{cm}}{P}$.

For frames compressed by spreading factor reduction $N_{data,*}^{cm} = \frac{N'_{data,*}}{2}$.

For frames compressed by higher layer scheduling the exact value of $N_{data,*}^{cm}$ is dependent on the TGL which is signalled from higher layers. It can be calculated as $N_{data,*}^{cm} = N'_{data,*} - N_{TGL}$.

N_{TGL} is the number of bits that are located within the transmission gap and defined as:

$$N_{TGL} = \begin{cases} \frac{TGL}{15} \times N'_{data,*}, & \text{if } N_{first} + TGL \leq 15 \\ \frac{15 - N_{first}}{15} \times N'_{data,*}, & \text{in first frame if } N_{first} + TGL > 15 \\ \frac{TGL - (15 - N_{first})}{15} \times N'_{data,*}, & \text{in second frame if } N_{first} + TGL > 15 \end{cases}$$

N_{first} and TGL are defined in clause 4.4.

The bits output from the DTX insertion block are denoted by $w_1, w_2, w_3, \dots, w_{(PR)}$. Note that these bits are four valued in case of compressed mode by puncturing, and three valued otherwise. They are defined by the following relations:

$$\begin{aligned} w_k &= s_k & k &= 1, 2, 3, \dots, S \\ w_k &= \delta & k &= S + 1, S + 2, S + 3, \dots, PR \end{aligned}$$

where DTX indication bits are denoted by δ . Here $s_k \in \{0, 1, p\}$ and $\delta \in \{0, 1\}$.

4.2.10 Physical channel segmentation

When more than one PhCH is used, physical channel segmentation divides the bits among the different PhCHs. The bits input to the physical channel segmentation are denoted by $x_1, x_2, x_3, \dots, x_X$, where X is the number of bits input to the physical channel segmentation block. The number of PhCHs is denoted by P .

The bits after physical channel segmentation are denoted $u_{p,1}, u_{p,2}, u_{p,3}, \dots, u_{p,U}$, where p is PhCH number and U is the number of bits in one radio frame for each PhCH, i.e. $U = (X - N_{TGL} - (N_{data,*} - N'_{data,*})) / P$ for compressed mode by puncturing, and $U = \frac{X}{P}$ otherwise. The relation between x_k and $u_{p,k}$ is given below.

For all modes, some bits of the input flow are mapped to each code until the number of bits on the code is U . For modes other than compressed mode by puncturing, all bits of the input flow are taken to be mapped to the codes. For compressed mode by puncturing, only the bits of the input flow not corresponding to bits p are taken to be mapped to the codes, each bit p is removed to ensure creation the gap required by the compressed mode, as described below.

Bits on first PhCH after physical channel segmentation:

$$u_{1,k} = x_{f(k)} \quad k = 1, 2, \dots, U$$

Bits on second PhCH after physical channel segmentation:

$$u_{2,k} = x_{f(k+U)} \quad k = 1, 2, \dots, U$$

...

Bits on the P^{th} PhCH after physical channel segmentation:

$$u_{P,k} = x_{f(k+(P-1) \times U)} \quad k = 1, 2, \dots, U$$

where f is such that:

- For modes other than compressed mode by puncturing, $x_{f(k)} = x_k$, i.e. $f(k) = k$, for all k .
- For compressed mode by puncturing, bit $u_{1,1}$ corresponds to the bit x_k with smallest index k when the bits p are not counted, bit $u_{1,2}$ corresponds to the bit x_k with second smallest index k when the bits p are not counted, and so on for bits $u_{1,3}, \dots, u_{1,U}, u_{2,1}, u_{2,2}, \dots, u_{2,U}, \dots, u_{P,1}, u_{P,2}, \dots, u_{P,U}$.

4.2.10.1 Relation between input and output of the physical segmentation block in uplink

The bits input to the physical segmentation are denoted by $s_1, s_2, s_3, \dots, s_S$. Hence, $x_k = s_k$ and $Y = S$.

4.2.10.2 Relation between input and output of the physical segmentation block in downlink

The bits input to the physical segmentation are denoted by $w_1, w_2, w_3, \dots, w_{(PU)}$. Hence, $x_k = w_k$ and $Y = PU$.

4.2.11 2nd interleaving

The 2nd interleaving is a block interleaver and consists of bits input to a matrix with padding, the inter-column permutation for the matrix and bits output from the matrix with pruning. The bits input to the block interleaver are denoted by $u_{p,1}, u_{p,2}, u_{p,3}, \dots, u_{p,U}$, where p is PhCH number and U is the number of bits in one radio frame for one PhCH. The output bit sequence from the block interleaver is derived as follows:

- 1) Assign $C2 = 30$ to be the number of columns of the matrix. The columns of the matrix are numbered $0, 1, 2, \dots, C2 - 1$ from left to right.
- 2) Determine the number of rows of the matrix, $R2$, by finding minimum integer $R2$ such that:

$$U \leq R2 \times C2.$$

The rows of rectangular matrix are numbered $0, 1, 2, \dots, R2 - 1$ from top to bottom.

- 3) Write the input bit sequence $u_{p,1}, u_{p,2}, u_{p,3}, \dots, u_{p,U}$ into the $R2 \times C2$ matrix row by row starting with bit $y_{p,1}$ in column 0 of row 0:

$$\begin{bmatrix} y_{p,1} & y_{p,2} & y_{p,3} & \dots & y_{p,C2} \\ y_{p,(C2+1)} & y_{p,(C2+2)} & y_{p,(C2+3)} & \dots & y_{p,(2 \times C2)} \\ \vdots & \vdots & \vdots & \dots & \vdots \\ y_{p,((R2-1) \times C2+1)} & y_{p,((R2-1) \times C2+2)} & y_{p,((R2-1) \times C2+3)} & \dots & y_{p,(R2 \times C2)} \end{bmatrix}$$

where $y_{p,k} = u_{p,k}$ for $k = 1, 2, \dots, U$ and if $R2 \times C2 > U$, the dummy bits are padded such that $y_{p,k} = 0$ or 1 for $k = U + 1, U + 2, \dots, R2 \times C2$. These dummy bits are pruned away from the output of the matrix after the inter-column permutation.

- 4) Perform the inter-column permutation for the matrix based on the pattern $\langle P2(j) \rangle_{j \in \{0,1,\dots,C2-1\}}$ that is shown in table 7, where $P2(j)$ is the original column position of the j -th permuted column. After permutation of the columns, the bits are denoted by $y'_{p,k}$.

$$\begin{bmatrix} y'_{p,1} & y'_{p,(R2+1)} & y'_{p,(2 \times R2+1)} & \cdots & y'_{p,((C2-1) \times R2+1)} \\ y'_{p,2} & y'_{p,(R2+2)} & y'_{p,(2 \times R2+2)} & \cdots & y'_{p,((C2-1) \times R2+2)} \\ \vdots & \vdots & \vdots & \cdots & \vdots \\ y'_{p,R2} & y'_{p,(2 \times R2)} & y'_{p,(3 \times R2)} & \cdots & y'_{p,(C2 \times R2)} \end{bmatrix}$$

- 5) The output of the block interleaver is the bit sequence read out column by column from the inter-column permuted $R2 \times C2$ matrix. The output is pruned by deleting dummy bits that were padded to the input of the matrix before the inter-column permutation, i.e. bits $y'_{p,k}$ that corresponds to bits $y_{p,k}$ with $k > U$ are removed from the output. The bits after 2nd interleaving are denoted by $v_{p,1}, v_{p,2}, \dots, v_{p,U}$, where $v_{p,1}$ corresponds to the bit $y'_{p,k}$ with smallest index k after pruning, $v_{p,2}$ to the bit $y'_{p,k}$ with second smallest index k after pruning, and so on.

Table 7: Inter-column permutation pattern for 2nd interleaving

Number of columns C2	Inter-column permutation pattern $\langle P2(0), P2(1), \dots, P2(C2-1) \rangle$
30	$\langle 0, 20, 10, 5, 15, 25, 3, 13, 23, 8, 18, 28, 1, 11, 21, 6, 16, 26, 4, 14, 24, 19, 9, 29, 12, 2, 7, 22, 27, 17 \rangle$

4.2.12 Physical channel mapping

The PhCH for both uplink and downlink is defined in TS 101 851-1-3 [1]. The bits input to the physical channel mapping are denoted by $v_{p,1}, v_{p,2}, \dots, v_{p,U}$, where p is the PhCH number and U is the number of bits in one radio frame for one PhCH. The bits $v_{p,k}$ are mapped to the PhCHs so that the bits for each PhCH are transmitted over the air in ascending order with respect to k .

In compressed mode, no bits are mapped to certain slots of the PhCH(s). If $N_{first} + TGL \leq 15$, no bits are mapped to slots N_{first} to N_{last} . If $N_{first} + TGL > 15$, i.e. the transmission gap spans two consecutive radio frames, the mapping is as follows:

- In the first radio frame, no bits are mapped to slots $N_{first}, N_{first} + 1, N_{first} + 2, \dots, 14$.
- In the second radio frame, no bits are mapped to the slots $0, 1, 2, \dots, N_{last}$.

TGL , N_{first} , and N_{last} are defined in clause 4.4.

4.2.12.1 Uplink

In uplink, the PhCHs used during a radio frame are either completely filled with bits that are transmitted over the air or not used at all. The only exception is when the UE is in compressed mode. The transmission can then be turned off during consecutive slots of the radio frame.

4.2.12.2 Downlink

In downlink, the PhCHs do not need to be completely filled with bits that are transmitted over the air. Values $v_{p,k} \notin \{0, 1\}$ correspond to DTX indicators, which are mapped to the DPCCH/DPDCH fields but are not transmitted over the air.

During compressed mode by reducing the spreading factor by 2, the data bits are always mapped into 7,5 slots within a compressed frame. No bits are mapped to the DPDCH field as follows:

If $N_{first} + TGL \leq 15$, i.e. the transmission gap spans one radio frame,

if $N_{first} + 7 \leq 14$

no bits are mapped to slots $N_{first}, N_{first} + 1, N_{first} + 2, \dots, N_{first} + 6$

no bits are mapped to the first $(N_{Data1} + N_{Data2})/2$ bit positions of slot $N_{first} + 7$

else

no bits are mapped to slots $N_{first}, N_{first} + 1, N_{first} + 2, \dots, 14$

no bits are mapped to slots $N_{first} - 1, N_{first} - 2, N_{first} - 3, \dots, 8$

no bits are mapped to the last $(N_{Data1} + N_{Data2})/2$ bit positions of slot 7

endif

If $N_{first} + TGL > 15$, i.e. the transmission gap spans two consecutive radio frames,

In the first radio frame, no bits are mapped to last $(N_{Data1} + N_{Data2})/2$ bit positions in slot 7 as well as to slots 8, 9, 10, ..., 14.

In the second radio frame, no bits are mapped to slots 0, 1, 2, ..., 6 as well as to first $(N_{Data1} + N_{Data2})/2$ bit positions in slot 7.

N_{Data1} and N_{Data2} are defined in TS 101 851-1-3 [1].

4.2.13 Restrictions on different types of CCTrCHs

Restrictions on the different types of CCTrCHs are described in general terms in TS 125 302 [4]. In this clause those restrictions are given with layer 1 notation.

4.2.13.1 Uplink Dedicated channel (DCH)

The maximum value of the number of TrCHs I in a CCTrCH, the maximum value of the number of transport blocks M_i on each transport channel, and the maximum value of the number of DPDCHs P are given from the UE capability class.

4.2.13.2 Random Access Channel (RACH)

- There can only be one TrCH in each RACH CCTrCH, i.e. $I = 1$, $s_k = f_{1k}$ and $S = V_1$.
- The maximum value of the number of transport blocks M_1 on the transport channel is given from the UE capability class.
- The transmission time interval is either 10 ms or 20 ms.
- Only one PRACH is used, i.e. $P = 1$, $u_{1k} = s_k$, and $U = S$.
- The Static rate matching parameter RM_1 is not provided by higher layer signalling on the System information as the other transport channel parameters. Any value may be used as there is one transport channel in the CCTrCH, hence one transport channel per Transport Format Combination and no need to do any balancing between multiple transport channels.

4.2.13.3 Downlink Dedicated CHannel (DCH)

The maximum value of the number of TrCHs I in a CCTrCH, the maximum value of the number of transport blocks M_i on each transport channel, and the maximum value of the number of DPDCHs P are given from the UE capability class.

4.2.13.4 Broadcast channel (BCH)

- There can only be one TrCH in the BCH CCTrCH, i.e. $I = 1$, $s_k = f_{1k}$, and $S = V_1$.
- There can only be one transport block in each transmission time interval, i.e. $M_1 = 1$.
- All transport format attributes have predefined values which are provided in TS 125 302 [4] apart from the rate matching RM_1 .
- The Static rate matching parameter RM_1 is not provided by higher layer signalling neither fixed. Any value may be used as there is one transport channel in the CCTrCH, hence one transport channel per Transport Format Combination and no need to do any balancing between multiple transport channels.
- Only one primary CCPCH is used, i.e. $P = 1$.

4.2.13.5 Forward access and paging channels (FACH and PCH)

- The maximum value of the number of TrCHs I in a CCTrCH and the maximum value of the number of transport blocks M_i on each transport channel are given from the UE capability class.
- The transmission time interval for TrCHs of PCH type is always 10 ms.
- Only one secondary CCPCH is used per CCTrCH, i.e. $P = 1$.

4.2.14 Multiplexing of different transport channels into one CCTrCH, and mapping of one CCTrCH onto physical channels

The following rules shall apply to the different transport channels which are part of the same CCTrCH:

- 1) Transport channels multiplexed into one CCTrCH shall have co-ordinated timings. When the TFCS of a CCTrCH is changed because one or more transport channels are added to the CCTrCH or reconfigured within the CCTrCH, or removed from the CCTrCH, the change may only be made at the start of a radio frame with CFN fulfilling the relation:

$$\text{CFN mod } F_{\max} = 0,$$

where F_{\max} denotes the maximum number of radio frames within the transmission time intervals of all transport channels which are multiplexed into the same CCTrCH, including any transport channels i which are added, reconfigured or have been removed, and CFN denotes the connection frame number of the first radio frame of the changed CCTrCH.

After addition or reconfiguration of a transport channel i within a CCTrCH, the TTI of transport channel i may only start in radio frames with CFN fulfilling the relation:

$$\text{CFN mod } F_i = 0.$$

- 2) Only transport channels with the same active set can be mapped onto the same CCTrCH.
- 3) Different CCTrCHs cannot be mapped onto the same PhCH.
- 4) One CCTrCH shall be mapped onto one or several PhCHs. These physical channels shall all have the same SF.
- 5) Dedicated Transport channels and common transport channels cannot be multiplexed into the same CCTrCH.
- 6) For the common transport channels, only the FACH and PCH may belong to the same CCTrCH.

There are hence two types of CCTrCH:

- 1) CCTrCH of dedicated type, corresponding to the result of coding and multiplexing of one or several DCHs.
- 2) CCTrCH of common type, corresponding to the result of the coding and multiplexing of a common channel, RACH in the uplink, BCH, or FACH/PCH for the downlink.

4.2.14.1 Allowed CCTrCH combinations for one UE

4.2.14.1.1 Allowed CCTrCH combinations on the uplink

A maximum of one CCTrCH is allowed for one UE on the uplink. It can be either:

- 1) one CCTrCH of dedicated type;
- 2) one CCTrCH of common type.

4.2.14.1.2 Allowed CCTrCH combinations on the downlink

The following CCTrCH combinations for one UE are allowed:

- x CCTrCH of dedicated type + y CCTrCH of common type. The allowed combination of CCTrCHs of dedicated and common type is given from UE radio access capabilities. The maximum number of CCTrCHs of common type for FACH is determined from UE capabilities.

NOTE 1: There is only one DPCCCH in the uplink, hence one TPC bits flow on the uplink to control possibly the different DPDCHs on the downlink, part of the same or several CCTrCHs.

NOTE 2: There is only one DPCCCH in the downlink, even with multiple CCTrCHs. With multiple CCTrCHs, the DPCCCH is transmitted on one of the physical channels of that CCTrCH which has the smallest SF among the multiple CCTrCHs. Thus there is only one TPC command flow and only one TFCI word in downlink even with multiple CCTrCHs.

NOTE 3: In the current release, only 1 CCTrCH of dedicated type is supported.

4.2.15 Downlink data randomization

In optional mode A, the following data scrambling is applied:

For a downlink transport DCH, the bits output by the 2nd interleaver can be randomized, prior to mapping to the corresponding physical channel(s). This option is enabled by higher layers.

The scrambling sequence is a segment of a Maximum Length (ML) sequence. The polynomial for the pseudo-random binary sequence generator is:

$$G(D) = D^{20} + D^9 + D^5 + D^3 + 1.$$

The shift register generating the sequence is loaded with the sequence 00000100101010000000 every 720 ms, that is, every 72 radio frames. The first bit at the output of the generator is applied to the first bit of the radio frame for which (SFN modulo 72) = 0 in the corresponding BCH.

The randomizer/de-randomizer operation is shown in figure 8a, where Input Data can stand both for clear and randomized data, yielding respectively randomized and de-randomized data at the output.

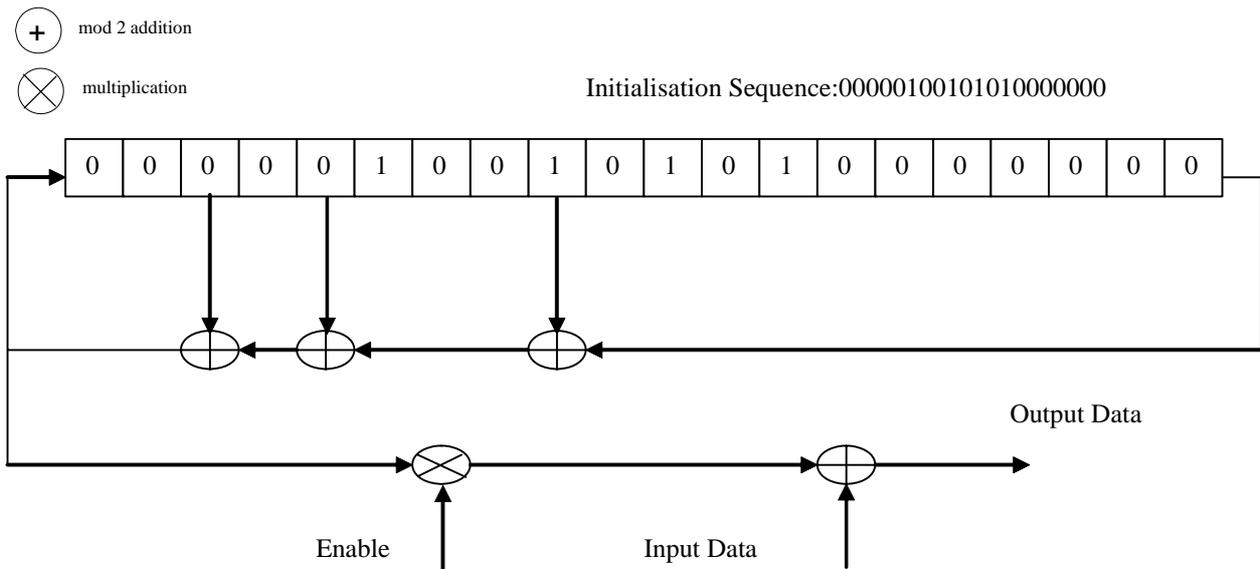

Figure 8a: Scrambler operation (Optional mode A)

4.3 Transport format detection

If the transport format set of a TrCH i contains more than one transport format, the transport format can be detected according to one of the following methods:

- TFCI based detection: This method is applicable when the transport format combination is signalled using the TFCI field;
- explicit blind detection: This method typically consists of detecting the TF of TrCH i by use of channel decoding and CRC check;
- guided detection: This method is applicable when there is at least one other TrCH i' , hereafter called guiding TrCH, such that:
 - the guiding TrCH has the same TTI duration as the TrCH under consideration, i.e. $F_1 = F_1'$;
 - different TFs of the TrCH under consideration correspond to different TFs of the guiding TrCH;
 - explicit blind detection is used on the guiding TrCH.

If the transport format set for a TrCH i does not contain more than one transport format with more than zero transport blocks, no explicit blind transport format detection needs to be performed for this TrCH. The UE can use guided detection for this TrCH or single transport format detection, where the UE always assumes the transport format corresponding to more than zero transport blocks for decoding.

For uplink, blind transport format detection is a network controlled option. For downlink, the UE shall be capable of performing blind transport format detection, if certain restrictions on the configured transport channels are fulfilled.

4.3.1 Blind transport format detection

When no TFCI is available then explicit blind detection or guided detection shall be performed on all TrCHs within the CCTrCH that have more than one transport format and that do not use single transport format detection. The UE shall only be required to support blind transport format detection if all of the following restrictions are fulfilled:

- 1) only one CCTrCH is received by the UE;

If only one CCTrCH is received by the UE, the following conditions apply to that CCTrCH and those TrCHs that are multiplexed on the CCTrCH.

- 2) the number of CCTrCH bits received per radio frame is 600 or less;
- 3) the number of transport format combinations of the CCTrCH is 64 or less;
- 4) fixed positions of the transport channels are used on the CCTrCH to be detectable;
- 5) convolutional coding is used on all explicitly detectable TrCHs;
- 6) CRC with non-zero length is appended to all transport blocks on all explicitly detectable TrCHs;
- 7) at least one transport block shall be transmitted per TTI on each explicitly detectable TrCH;
- 8) the number of explicitly detectable TrCHs is 3 or less;
- 9) for all explicitly detectable TrCHs i , the number of code blocks in one TTI (C_i) shall not exceed 1;
- 10) the sum of the transport format set sizes of all explicitly detectable TrCHs, is 16 or less. The transport format set size is defined as the number of transport formats within the transport format set;
- 11) there is at least one TrCH that can be used as the guiding transport channel for all transport channels using guided detection.

Examples of blind transport format detection methods are given in annex A.

4.3.2 Single transport format detection

When no TFCI is available, then single transport format detection shall be applied on all TrCHs within the CCTrCH that have a transport format set not containing more than one transport format with more than zero transport blocks and that do not use guided detection. The UE shall only be required to support single transport format detection if the following restrictions are fulfilled:

- 1) for each transport channel that is single transport format detected, CRC with non-zero length is appended to all transport blocks within the non-zero transport block transport format;
- 2) fixed positions of the transport channels are used on the CCTrCH to be detectable.

4.3.3 Transport format detection based on TFCI

If a TFCI is available, then TFCI based detection shall be applicable to all TrCHs within the CCTrCH. The TFCI informs the receiver about the transport format combination of the CCTrCHs. As soon as the TFCI is detected, the transport format combination, and hence the transport formats of the individual transport channels are known.

If higher layers indicate that S-CCPCHs can be soft combined, then the same TFCI is used on those S-CCPCHs during the radio frames when soft combining is possible. The UE may therefore detect TFCI on one S-CCPCH to determine the TFCI on all S-CCPCHs that can be soft combined. (S-CCPCH soft combining is further specified in TS 101 851-4-3 [3]).

4.3.4 Coding of Transport Format Combination Indicator (TFCI)

The TFCI is encoded using a (32, 10) sub-code of the second order Reed-Muller code. The coding procedure is as shown in figure 9.

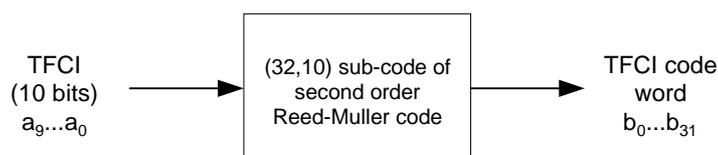

Figure 9: Channel coding of TFCI information bits

If the TFCI consist of less than 10 bits, it is padded with zeros to 10 bits, by setting the most significant bits to zero. The length of the TFCI code word is 32 bits.

The code words of the (32,10) sub-code of second order Reed-Muller code are linear combination of 10 basis sequences. The basis sequences are as in table 8.

Table 8: Basis sequences for (32,10) TFCI code

30	0	0	0	0	0	1	0	0	0	0
31	0	0	0	0	1	1	1	0	0	0

The TFCI information bits $a_0, a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9$ (where a_0 is LSB and a_9 is MSB) shall correspond to the TFC index (expressed in unsigned binary form) defined by the RRC layer to reference the TFC of the CCTrCH in the associated DPCH radio frame.

The output code word bits b_i are given by:

$$b_i = \sum_{n=0}^9 (a_n \times M_{i,n}) \bmod 2$$

where $i = 0, \dots, 31$.

The output bits are denoted by $b_k, k = 0, 1, 2, \dots, 31$.

In downlink, when the SF < 128 the encoded TFCI code words are repeated yielding 8 encoded TFCI bits per slot in normal mode and 16 encoded TFCI bits per slot in compressed mode. Mapping of repeated bits to slots is explained in clause 4.3.5.

4.3.5 Mapping of TFCI words

4.3.5.1 Mapping of TFCI word in normal mode

The bits of the code word are directly mapped to the slots of the radio frame. Within a slot the bit with lower index is transmitted before the bit with higher index. The coded bits b_k , are mapped to the transmitted TFCI bits d_k , according to the following formula:

$$d_k = b_{k \bmod 32}$$

For uplink physical channels regardless of the SF and downlink physical channels, if $SF \geq 128$, $k = 0, 1, 2, \dots, 29$. Note that this means that bits b_{30} and b_{31} are not transmitted.

For downlink physical channels whose $SF < 128$, $k = 0, 1, 2, \dots, 119$. Note that this means that bits b_0 to b_{23} are transmitted four times and bits b_{24} to b_{31} are transmitted three times.

4.3.5.2 Mapping of TFCI word in compressed mode

The mapping of the TFCI bits in compressed mode is different for uplink, downlink with $SF \geq 128$ and downlink with $SF < 128$.

4.3.5.2.1 Uplink compressed mode

For uplink compressed mode, the slot format is changed so that no TFCI coded bits are lost. The different slot formats in compressed mode do not match the exact number of TFCI coded bits for all possible TGLs. Repetition of the TFCI bits is therefore used.

Denote the number of bits available in the TFCI fields of one compressed radio frame by D and the number of bits in the TFCI field in a slot by N_{TFCI} . The parameter E is used to determine the number of the first TFCI bit to be repeated.

$E = N_{\text{first}} N_{\text{TFCI}}$, if the start of the transmission gap is allocated to the current frame.

$E = 0$, if the start of the transmission gap is allocated to the previous frame and the end of the transmission gap is allocated to the current frame.

The TFCI coded bits b_k are mapped to the bits in the TFCI fields d_k . The following relations define the mapping for each compressed frame.

$$d_k = b_k$$

where $k = 0, 1, 2, \dots, \min(31, D - 1)$.

If $D > 32$, the remaining positions are filled by repetition (in reversed order):

$$d_{D-k-1} = b_{(E+k) \bmod 32}$$

where $k = 0, \dots, D-33$.

4.3.5.2.2 Downlink compressed mode

For downlink compressed mode, the slot format is changed so that no TFCI coded bits are lost. The different slot formats in compressed mode do not match the exact number of TFCI bits for all possible TGLs. DTX is therefore used if the number of bits available in the TFCI fields in one compressed frame exceeds the number of TFCI bits given from the slot format. The block of bits in the TFCI fields where DTX is used starts on the first TFCI field after the transmission gap. If there are more bits available in the TFCI fields before the transmission gap than TFCI bits, DTX is also used on the bits in the last TFCI fields before the transmission gap.

Denote the number of bits available in the TFCI fields of one compressed radio frame by D and the number of bits in the TFCI field in a slot by N_{TFCI} . The parameter E is used to determine the position of the first bit in the TFCI field on which DTX is used.

$E = N_{\text{first}} N_{\text{TFCI}}$, if the start of the transmission gap is allocated to the current frame.

$E = 0$, if the start of the transmission gap is allocated to the previous frame and the end of the transmission gap is allocated to the current frame.

Denote the total number of TFCI bits to be transmitted by F . $F = 32$ for slot formats nA or nB , where $n = 0, 1, \dots, 11$ (see TS 101 851-1-3 [1]). Otherwise, $F = 128$. The TFCI coded bits b_k are mapped to the bits in the TFCI fields d_k . The following relations define the mapping for each compressed frame.

If $E > 0$,

$$d_k = b_{k \bmod 32}$$

where $k = 0, 1, 2, \dots, \min(E, F) - 1$.

If $E < F$,

$$d_{k+D-F} = b_{k \bmod 32}$$

where $k = E, \dots, F - 1$.

DTX is used on d_k where $k = \min(E, F), \dots, \min(E, F) + D - F - 1$.

4.4 Compressed mode

In compressed frames, TGL slots from N_{first} to N_{last} are not used for transmission of data. As illustrated in figure 10, the instantaneous transmit power is increased in the compressed frame in order to keep the quality (BER, FER, etc.) unaffected by the reduced processing gain. The amount of power increase depends on the transmission time reduction method (see clause 4.4.3). What frames are compressed, are decided by the network. When in compressed mode, compressed frames can occur periodically, as illustrated in figure 10, or requested on demand. The rate and type of compressed frames is variable and depends on the environment and the measurement requirements.

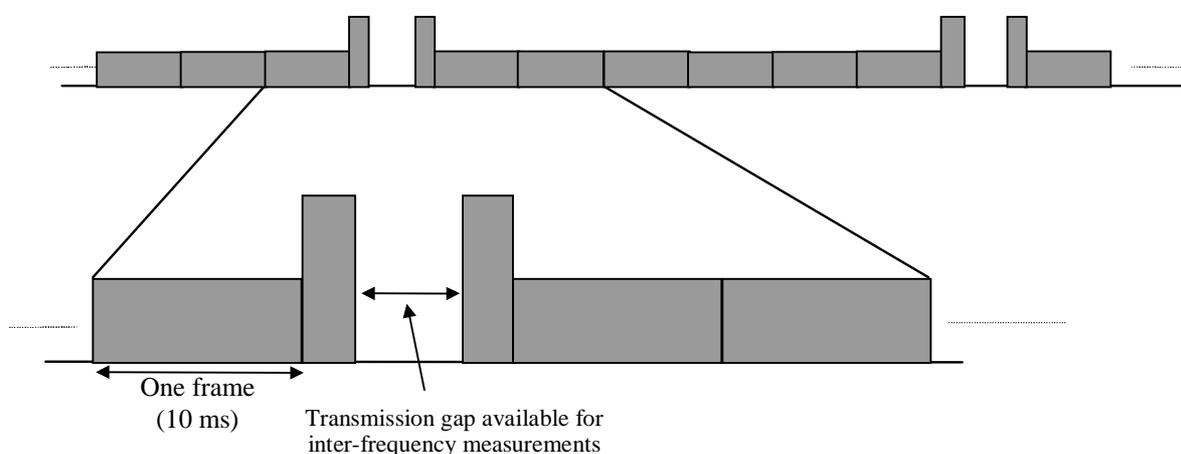

Figure 10: Compressed mode transmission

4.4.1 Frame structure in the uplink

The frame structure for uplink compressed frames is illustrated in figure 11.

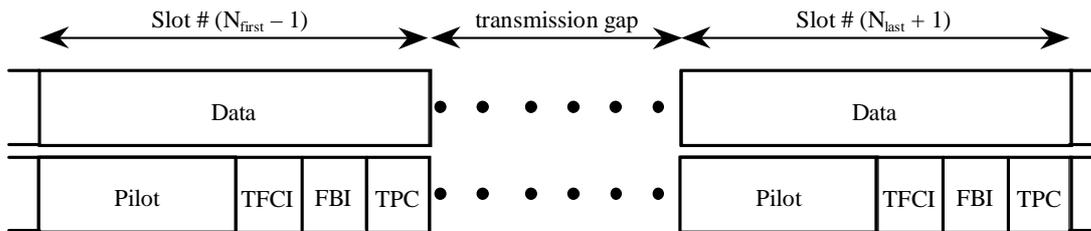

Figure 11: Frame structure in uplink compressed transmission

4.4.2 Frame structure types in the downlink

The pilot field of the last slot in the transmission gap is transmitted. Transmission is turned off during the rest of the transmission gap (figure 12).

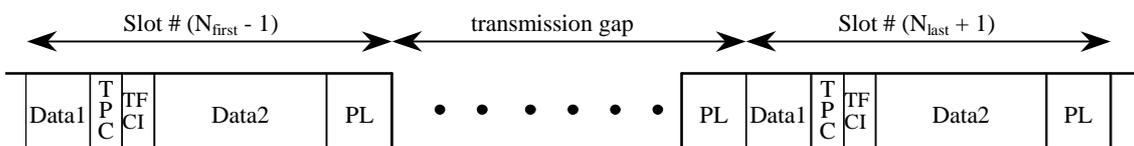

Figure 12: Frame structure types in downlink compressed transmission

4.4.3 Transmission time reduction method

When in compressed mode, the information normally transmitted during a 10 ms frame is compressed in time. The mechanisms provided for achieving this are puncturing, reduction of the spreading factor by a factor of two, and higher layer scheduling. In the downlink, all methods are supported while compressed mode by puncturing is not used in the uplink. The maximum idle length is defined to be 7 slots per one 10 ms frame. The slot formats that are used in compressed frames are listed in TS 101 851-1-3 [1].

4.4.3.1 Compressed mode by puncturing

Rate matching is applied for creating a transmission gap in one or two frames. The algorithm for rate matching as described in clause 4.2.7 is used.

4.4.3.2 Compressed mode by reducing the spreading factor by 2

The Spreading Factor (SF) can be reduced by 2 during one compressed radio frame to enable the transmission of the information bits in the remaining time slots of the compressed frame. This method is not supported for SF = 4.

On the downlink, USRAN can also order the UE to use a different scrambling code in a compressed frame than in a non-compressed frame. If the UE is ordered to use a different scrambling code in a compressed frame, then there is a one-to-one mapping between the scrambling code used in the non-compressed frame and the one used in the compressed frame, as described in TS 101 851-3-3 [2].

4.4.3.3 Compressed mode by higher layer scheduling

Compressed frames can be obtained by higher layer scheduling. Higher layers then set restrictions so that only a subset of the allowed TFCs is used in a compressed frame. The maximum number of bits that will be delivered to the physical layer during the compressed radio frame is then known and a transmission gap can be generated. Note that in the downlink, the TFCI field is expanded on the expense of the data fields and this shall be taken into account by higher layers when setting the restrictions on the TFCs. Compressed mode by higher layer scheduling shall not be used with fixed starting positions of the TrCHs in the radio frame.

4.4.4 Transmission gap position

Transmission gaps can be placed at different positions as shown in figures 13 and 14 for each purpose such as interfrequency power measurement, acquisition of control channel of other system/carrier, and actual handover operation.

When using single frame method, the transmission gap is located within the compressed frame depending on the transmission gap length (TGL) as shown in figure 13 (1). When using double frame method, the transmission gap is located on the center of two connected frames as shown in figure 13 (2).

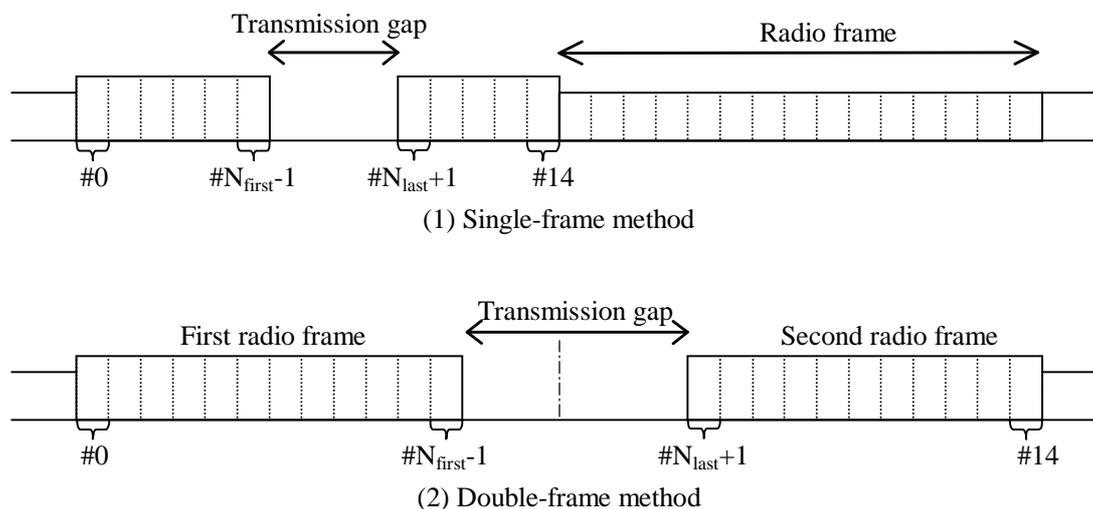

Figure 13: Transmission gap position

Parameters of the transmission gap positions are calculated as follows.

TGL is the number of consecutive idle slots during the compressed mode transmission gap:

$$\text{TGL} = 3, 4, 5, 7, 10, 14.$$

N_{first} specifies the starting slot of the consecutive idle slots:

$$N_{\text{first}} = 0, 1, 2, 3, \dots, 14.$$

N_{last} shows the number of the final idle slot and is calculated as follows:

$$\text{If } N_{\text{first}} + \text{TGL} \leq 15, \text{ then } N_{\text{last}} = N_{\text{first}} + \text{TGL} - 1 \text{ (in the same frame);}$$

$$\text{If } N_{\text{first}} + \text{TGL} > 15, \text{ then } N_{\text{last}} = (N_{\text{first}} + \text{TGL} - 1) \bmod 15 \text{ (in the next frame).}$$

When the transmission gap spans two consecutive radio frames, N_{first} and TGL must be chosen so that at least 8 slots in each radio frame are transmitted.

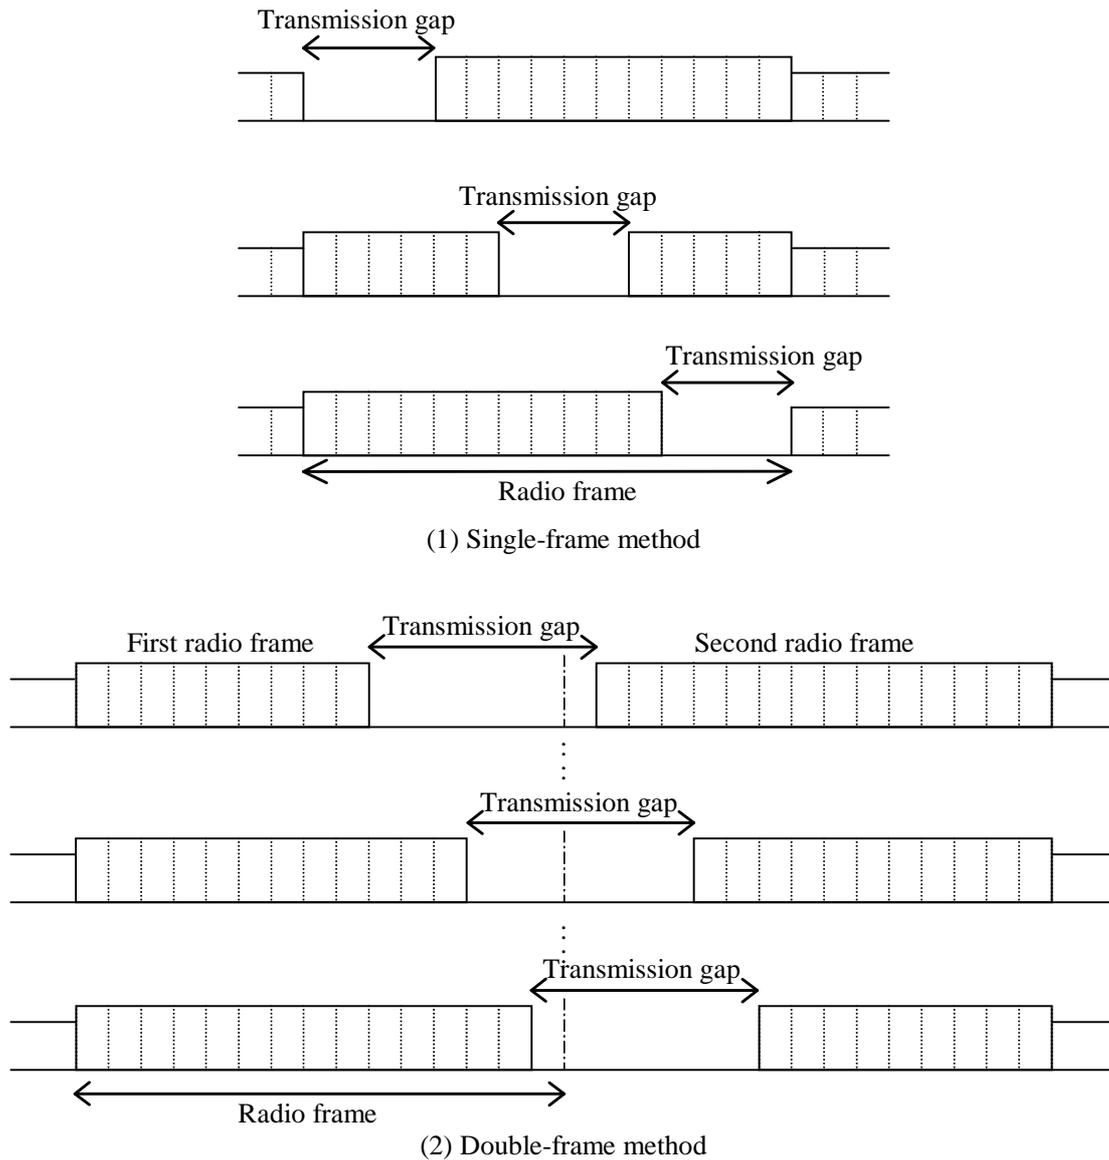

Figure 14: Transmission gap positions with different Nfirst

4.5 TPC command coding

In optional mode C, the following is applied to generate the 2-bit TPC command.

4.5.1 Transmission gap position

The 2-bit TPC command is encoded by repetition. The set of TPC command bits (a_0 , a_1) shall correspond to the TPC command (expressed in unsigned binary form) defined by the power control procedure [4].

The output code word bits b_i are given by:

$$b_k = a_k \bmod 2,$$

where $k = 0, \dots, 15$.

The output bits are denoted by b_k , $k = 0, 1, 2, \dots, 15$.

4.5.2 Mapping of TPC words

For both uplink and downlink channels, the bits of the code word are mapped to 15 slots of the radio frame. Within a slot the bit with lower index is transmitted before the bit with higher index. The coded bits b_k , are mapped to the transmitted TPC bits d_k , according to the following formula:

$$d_k = b_k \bmod 15,$$

where $k = 0, \dots, K-1$. The number of bits available in TPC fields of a radio frame, K , depends on the slot format used for the frame. Note that the no TPC bits are mapped to the slots in transmission gap.

Annex A (informative): Blind transport format detection

A.1 Blind transport format detection using fixed positions

A.1.1 Blind transport format detection using received power ratio

For the dual transport format case (the possible data rates are 0 and full rate, and CRC is only transmitted for full rate), blind transport format detection using received power ratio can be used.

The transport format detection is then done using average received power ratio of DPDCH to DPCCH. Define the following:

- P_c : Received power per bit of DPCCH calculated from all pilot and TPC bits per slot over a radio frame;
- P_d : Received power per bit of DPDCH calculated from X bits per slot over a radio frame;
- X : the number of DPDCH bits per slot when transport format corresponds to full rate;
- T : Threshold of average received power ratio of DPDCH to DPCCH for transport format detection.

The decision rule can then be formulated as:

If $P_d/P_c > T$ then:

- full rate transport format detected;

else

- zero rate transport format detected.

A.1.2 Blind transport format detection using CRC

For the multiple transport format case (the possible data rates are 0, ..., (full rate)/ r , ..., full rate, and CRC is transmitted for all transport formats), blind transport format detection using CRC can be used.

At the transmitter, the data stream with variable number of bits from higher layers is block-encoded using a cyclic redundancy check (CRC) and then convolutionally encoded. CRC parity bits are attached just after the data stream with variable number of bits as shown in figure A.1.

The receiver knows only the possible transport formats (or the possible end bit position $\{n_{\text{end}}\}$) by Layer-3 negotiation. The receiver performs Viterbi-decoding on the soft decision sample sequence. The correct trellis path of the Viterbi-decoder ends at the zero state at the correct end bit position.

The blind transport format detection method using CRC traces back the surviving trellis path ending at the zero state (hypothetical trellis path) at each possible end bit position to recover the data sequence. For each recovered data sequence error-detection is performed by checking the CRC, and if there is no error, the recovered sequence is declared to be correct.

The following variable is defined:

$$s(n_{\text{end}}) = -10 \log \left((a_0(n_{\text{end}}) - a_{\min}(n_{\text{end}})) / (a_{\max}(n_{\text{end}}) - a_{\min}(n_{\text{end}})) \right) \text{ [dB]} \quad (\text{A.1})$$

where $a_{\max}(n_{\text{end}})$ and $a_{\min}(n_{\text{end}})$ are the maximum and minimum path-metric values among all survivors at end bit position n_{end} , and $a_0(n_{\text{end}})$ is the path-metric value at zero state.

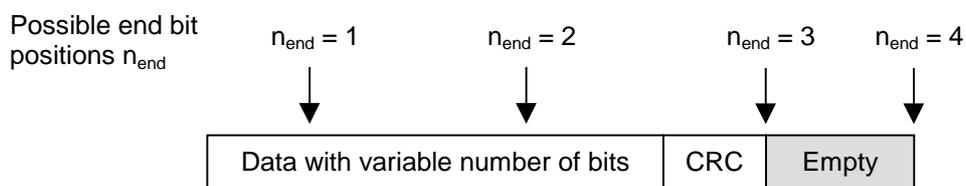

In order to reduce the probability of false detection (this happens if the selected path is wrong but the CRC misses the error detection), a path selection threshold D is introduced. The threshold D determines whether the hypothetical trellis path connected to the zero state should be traced back or not at each end bit position n_{end} . If the hypothetical trellis path connected to the zero state that satisfies:

$$s(n_{\text{end}}) \leq D \quad (\text{A.2})$$

is found, the path is traced back to recover the frame data, where D is the path selection threshold and a design parameter.

If more than one end bit positions satisfying (A.2) is found, the end bit position which has minimum value of $s(n_{\text{end}})$ is declared to be correct. If no path satisfying (A.2) is found even after all possible end bit positions have been exhausted, the received frame data is declared to be in error.

Figure A.2 shows the procedure of blind transport format detection using CRC.

NOTE: Four possible transport formats, and transmitted end bit position $n_{\text{end}} = 3$.

Figure A.1: An example of data with variable number of bits

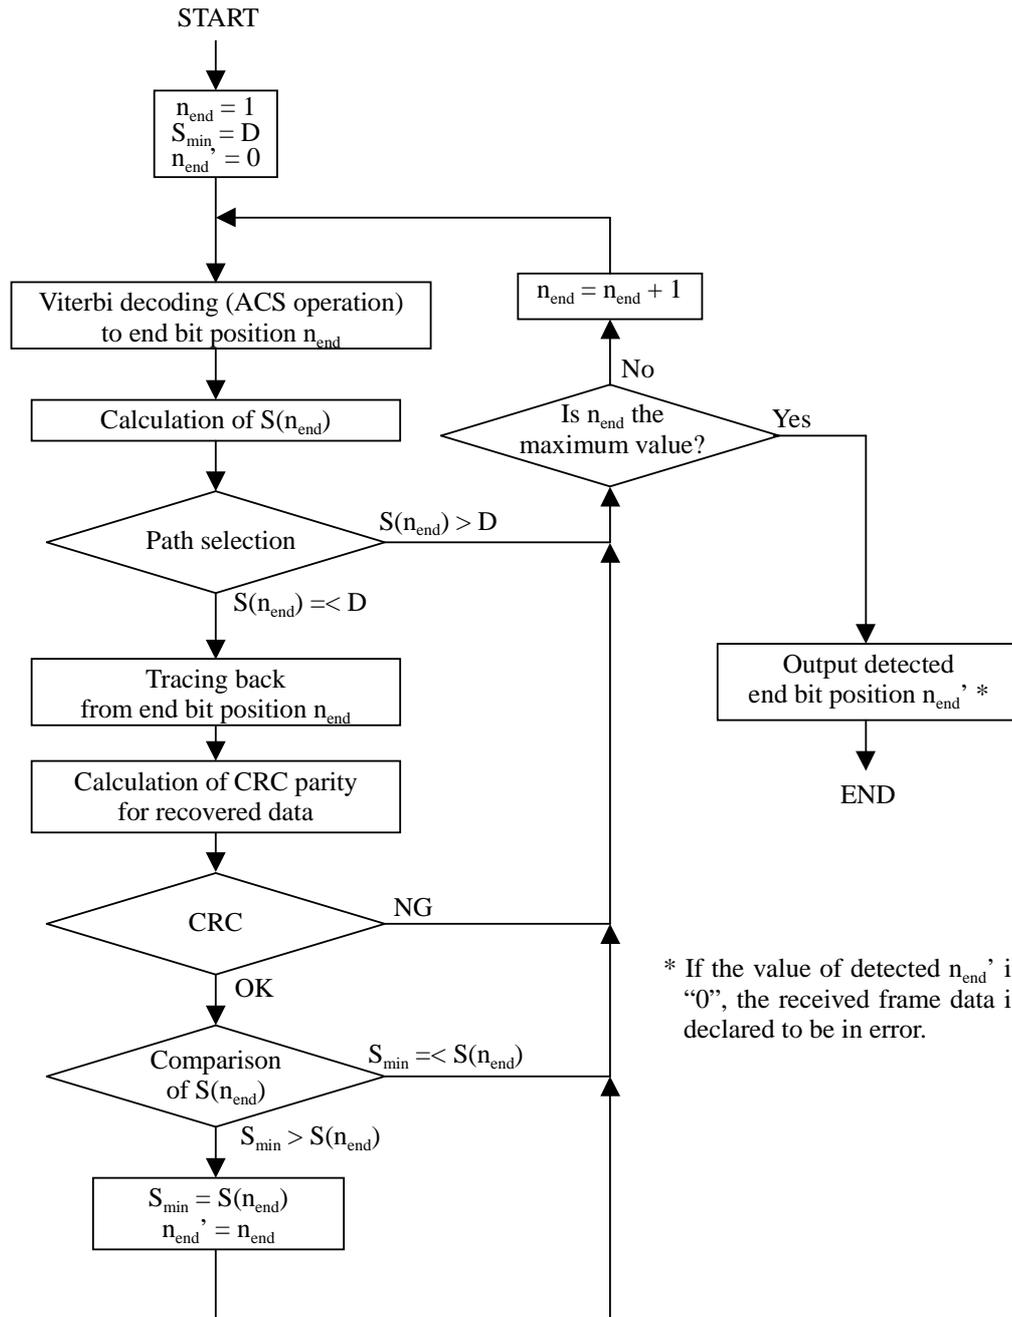

Figure A.2: Basic processing flow of blind transport format detection

Annex B (informative): Compressed mode idle lengths

Tables B.1 to B.3 show the resulting idle lengths for different transmission gap lengths, UL/DL modes and DL frame types. The idle lengths given are calculated purely from the slot and frame structures and the UL/DL offset. They do not contain margins for e.g. synthesizer switching.

B.1 Idle lengths for DL, UL and DL+UL compressed mode

Table B.1: Parameters for DL compressed mode

TGL	Spreading Factor	Idle length [ms]	Transmission time Reduction method	Idle frame Combining
3	512 to 4	1,73 to 1,99	Puncturing, Spreading factor division by 2 or Higher layer scheduling	(S) (D) = (1,2) or (2,1)
4		2,40 to 2,66		(S) (D) = (1,3), (2,2) or (3,1)
5		3,07 - 3,33		(S) (D) = (1,4), (2,3), (3, 2) or (4,1)
7		4,40 to 4,66		(S) (D) = (1,6), (2,5), (3,4), (4,3), (5,2) or (6,1)
10		6,40 to 6,66		(D) = (3,7), (4,6), (5,5), (6,4) or (7,3)
14		9,07 to 9,33		(D) = (7,7)

Table B.2: Parameters for UL compressed mode

TGL	Spreading Factor	Idle length [ms]	Transmission time Reduction method	Idle frame Combining
3	256 to 4	2,00	Spreading factor division by 2 or Higher layer scheduling	(S) (D) = (1,2) or (2,1)
4		2,67		(S) (D) = (1,3), (2,2) or (3,1)
5		3,33		(S) (D) = (1,4), (2,3), (3,2) or (4,1)
7		4,67		(S) (D) = (1,6), (2,5), (3,4), (4,3), (5,2) or (6,1)
10		6,67		(D) = (3,7), (4,6), (5,5), (6,4) or (7,3)
14		9,33		(D) = (7,7)

Table B.3: Parameters for combined UL/DL compressed mode

TGL	Spreading Factor	Idle length [ms]	Transmission time Reduction method	Idle frame Combining
3	DL: 512 to 4	1,47 to 1,73	DL: Puncturing, Spreading factor division by 2 or Higher layer scheduling	(S) (D) = (1,2) or (2,1)
4		2,13 to 2,39		(S) (D) = (1,3), (2,2) or (3,1)
5	UL: 256 to 4	2,80 to 3,06	UL: Spreading factor division by 2 or Higher layer scheduling	(S) (D) = (1,4), (2,3), (3,2) or (4,1)
7		4,13 to 4,39		(S) (D) = (1,6), (2,5), (3,4), (4,3), (5,2) or (6,1)
10		6,13 to 6,39		(D) = (3,7), (4,6), (5,5), (6,4) or (7,3)
14		8,80 to 9,06		(D) = (7,7)

(S): Single-frame method as shown in figure 13 (1).

(D): Double-frame method as shown in figure 13 (2). (x,y) indicates x: the number of idle slots in the first frame, y: the number of idle slots in the second frame.

NOTE: Compressed mode by spreading factor reduction is not supported when SF = 4 is used in normal mode.

Annex C (normative): Description of G-family enhancements

C.1 Definition of the optional modes A and C

The following two optional modes are defined in the G-family enhancements.

- Optional mode A: Operation with G-family features and A-family optional features which are identified in clause C.2 for performance enhancement.
- Optional mode C: Operation with G-family features and C-family optional features which are identified in clause C.3 for performance enhancement.

In order to keep backward compatibility with G-family, the G-family enhancements system should support G basic terminals as well as G enhanced terminals and the G enhanced terminals should be operated in the G family system. For this, the following terminal types are considered in the G-family enhancements system.

- Terminal type 1 including only G-family interface
- Terminal type 2 including G-family interface as well as optional mode A
- Terminal type 3 including G-family interface as well as optional mode C
- Terminal type 4 including G-family interface as well as both optional modes A and C

The information which types of terminals are supported in the targeted frame and/or the considered Base Station could be sent via broadcasting channel.

C.2 Description of Optional mode A

The following new features of SRI-A family are considering for the standardization of SRI-G-family enhancements. They are based on a synthetic view of SW-CDMA and WCDMA identified in TR 102 278 [i.6].

Table C.1: Description of A-family optional features

Features	Description
HPPICH	<ul style="list-style-type: none"> - Additional paging channel - Unspread BPSK signal packet of length 10 ms - Channel rate = 15 k symbol/s - Packet = preamble (24bits) +UW (12 bits) + data (114 bits)
Downlink data scrambling	<ul style="list-style-type: none"> - For downlink when interference mitigation is used - Prior to physical channel mapping - By a ML sequence with polynomial $1+X^{14}+X^{15}$ - Rate: 30 kbit/s

C.3 Description of Optional mode C

The following new features of SRI-C family are considering for the standardization of SRI-G-family enhancements.

Table C.2: Description of C-family optional features

Features	Description
Uplink random access	<ul style="list-style-type: none"> - Transmission of both preamble and message, together - Access frame: 2 radio frames
FBI/TPC bits generation and transmission	<ul style="list-style-type: none"> - TPC field: the reduction of the half of TPC field - FBI field: removal of 2 bits FBI field
Power control	<ul style="list-style-type: none"> - CLPC: a delay compensation power control scheme + prediction algorithm - SIR estimation from CPICH and S-CCPCH - 2-bit TPC command - OLPC algorithm using pilot diversity in option
Synchronization codes for downlink SCH in LEO constellation	<ul style="list-style-type: none"> - One so-called generalized hierarchical Golay sequence

Annex D (informative): Change history

This annex describes the differences relevant to TS 101 851-1-1 [i.8], TS 101 851-1-2 [i.9], TS 101 851-2-1 [i.10], TS 101 851-2-2 [i.11], TS 101 851-3-1 [i.12], TS 101 851-3-2 [i.13], TS 101 851-4-1 [i.14] and TS 101 851-4-2 [i.15].

D.1 A-family optional features

The following tables present summary on changes for TS 101 851-1-3 [1] to TS 101 851-4-3 [3] of SRI-G family, considering the harmonization with SRI-A family.

Table D.1: TS 101 851-1-3 [1]; Physical channels and mapping of transport channels into physical channels

Item Reference	Item	Actions
3.2 Abbreviations	-HPPICH for optional mode A	-To add HPPICH for high penetration paging
5.3.2.8 High penetration page indication channel	-HPICCH for optional mode A	-To define HPPICH for high penetration paging + Unspread BPSK signal packet of length 10 ms + Channel rate = 15 ksymbol/s + Packet = Preamble (24 bits) + UW (12 bits) + data (114 bits)

Table D.2: TS 101 851-2-3; Multiplexing and channel coding

Item Reference	Item	Actions
4.2 General coding/multiplexing of TrCHs	-Downlink data scrambling for optional mode A	-To add downlink data scrambling step between 2 nd interleaving and physical mapping
4.2.15 Downlink data scrambling	-Downlink data scrambling for optional mode A	-To define downlink data scrambling + A ML sequence with polynomial 1+X14+X15 + Rate: 30 kbit/s

D.2 C-family optional features

The following tables present summary on changes for TS 101 851-1-3 [1] to TS 101 851-4-3 [3] of SRI-G family, considering the harmonization with SRI-C family.

Table D.3: TS 101 851-1-3 [1]; Physical channels and mapping of transport channels into physical channels

Item Reference	Item	Actions
5.2.1 Dedicated uplink physical channels	-FBI/TPC field generation for the optional mode C	-Addition of statement related to deletion of FBI field for closed-loop transmit diversity and reduction as 1 bit for only SSDT -Reduction of the number of slot formats: Deletion of 2 bits FBI -Reduction of TPC field and extension of pilot field -Identification of new pilot patterns
5.2.2 Common uplink physical channels	-Uplink random access for the optional mode C	-Addition of modified structure of random-access transmission: transmission of both a preamble and a message -Identification of access frame -Based on ALOHA approach with fast acquisition indication -Optional RACH preamble: Np repetition of a sub-preamble and conjugation in the final sub-preamble
6.3.1 Dedicated downlink physical channels	-FBI/TPC field generation for the optional mode C	-Modification of TPC duration as one radio frame -Reduction of the TPC field as 1/2 and extension of the Data2 field
6.3.2 Common downlink physical channels	-Uplink random access for the optional mode C	-Identification on transmission of AI only on the first and 9 th access slots
8.1 Timing relation between physical channels	-Uplink random access for the optional mode C	-Identification on AICH sub-access frame
8.3 PRACH/AICH timing relation	-Uplink random access for the optional mode C	-Identification of modified PRACH/AICH timing relation in order to consider long round trip delay of satellite system and transmission of both preamble and message parts

Table D.4: TS 101 851-2-3; Multiplexing and channel coding

Item Reference	Item	Actions
4.5 TPC command coding	-FBI/TPC field generation for the optional mode C	-Identification of a new coding method of TPC command: 8 repetition of 2 bits TPC command -Identification of mapping of TPC words

Table D.5: TS 101 851-3-3 [2]; Spreading and modulation

Item Reference	Item	Actions
5.3.3 PRACH preamble codes	-Uplink random access transmission for the optional mode C	-Addition of new code construction: Nsp repetition of a sub-preamble and conjugation in the final sub-preamble -Identification of usage of other codes in order to distinguish even and odd sub-access frames
6.2.3 Synchronization codes	-Synchronization codes for downlink SCH in LEO constellation	-Identification of a new code generation method for LEO based mobile satellite system -Addition of modified synchronization codes as two hierarchical Golay sequences with 128 chip length

Table D.6: TS 101 851-4-3 [3]; Physical layer procedure

Item Reference	Item	Actions
5.1 Uplink power control	-Power control method for the optional mode C	-Identification of one power control per one frame duration -Identification of a new closed-loop power control with delay compensation algorithm in order to optimize the basic power control loop parameters, including the power control rate, power control step size, and the number of control levels -Identification of a new open-loop power control algorithm considering pilot diversity
5.2 Downlink power control	-Synchronization codes for downlink SCH in LEO constellation for the optional mode C	-Identification of one power control per one frame duration -Identification of a new closed-loop power control with delay compensation and prediction algorithms in order to optimize the basic power control loop parameters, including the power control rate, power control step size, and the number of control levels -Deletion of ID codes for 2 bit FBI in spot selection diversity transmit power control
6.1 Random access procedure	-Uplink random access transmission for the optional mode C	-Identification of access frame, even access frame and odd access frame -Identification of a new PRACH procedure with addition to selection of sub-access frame
6.1.1 RACH sub-channels	-Uplink random access transmission for the optional mode C	-Identification of a RACH sub-channel as a set of access frame
6.1.2 RACH access frame sets	-Uplink random access transmission for the optional mode C	-Identification of a new RACH access frame sets
