Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for ETSI members and non-members, and can be found in ETSI SR 000 314: "Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (https://ipr.etsi.org/).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by Joint Technical Committee (JTC) Broadcast of the European Broadcasting Union (EBU), Comité Européen de Normalisation ÉLECTrotechnique (CENELEC) and the European Telecommunications Standards Institute (ETSI).

NOTE 1: The EBU/ETSI JTC Broadcast was established in 1990 to co-ordinate the drafting of standards in the specific field of broadcasting and related fields. Since 1995 the JTC Broadcast became a tripartite body by including in the Memorandum of Understanding also CENELEC, which is responsible for the standardization of radio and television receivers. The EBU is a professional association of broadcasting organizations whose work includes the co-ordination of its members’ activities in the technical, legal, programme-making and programme-exchange domains. The EBU has active members in about 60 countries in the European broadcasting area; its headquarters is in Geneva.

European Broadcasting Union

Tel: +41 22 717 21 11
Fax: +41 22 717 24 81

The Eureka Project 147 was established in 1987, with funding from the European Commission, to develop a system for the broadcasting of audio and data to fixed, portable or mobile receivers. Their work resulted in the publication of European Standard, ETSI EN 300 401 [1], for DAB (see note 2) which now has worldwide acceptance.

NOTE 2: DAB is a registered trademark owned by one of the Eureka Project 147 partners.

The DAB family of standards is supported by World DAB, an organization with members drawn from broadcasting organizations and telecommunication providers together with companies from the professional and consumer electronics industry.

Modal verbs terminology

In the present document "shall", "shall not", "should", "should not", "may", "need not", "will", "will not", "can" and "cannot" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.
1 Scope

The present document defines the method to code and transmit audio services using the HE-AACv2 [2] audio coder for Eureka-147 Digital Audio Broadcasting (DAB) (ETSI EN 300 401 [1]) and details the necessary mandatory requirements for decoders. The permitted audio modes and the data protection and encapsulation are detailed. This audio coding scheme permits the full use of the PAD channel for carrying dynamic labels and user applications.

2 References

2.1 Normative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

Referenced documents which are not found to be publicly available in the expected location might be found at https://docbox.etsi.org/Reference.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are necessary for the application of the present document.

[1] ETSI EN 300 401 (V2.1.1): "Radio Broadcasting Systems; Digital Audio Broadcasting (DAB) to mobile, portable and fixed receivers".

2.2 Informative references

References are either specific (identified by date of publication and/or edition number or version number) or non-specific. For specific references, only the cited version applies. For non-specific references, the latest version of the referenced document (including any amendments) applies.

NOTE: While any hyperlinks included in this clause were valid at the time of publication, ETSI cannot guarantee their long term validity.

The following referenced documents are not necessary for the application of the present document but they assist the user with regard to a particular subject area.

[i.1] ISO/IEC 23003-1: "Information technology - MPEG audio technologies - Part 1: MPEG Surround".

3 Definitions, abbreviations and arithmetic operators

3.1 Definitions

For the purposes of the present document, the terms and definitions given in ETSI EN 300 401 [1] and the following apply:

access unit: access unit contains the audio samples for 20 ms, 30 ms, 40 ms or 60 ms of audio depending on the sampling rate of the AAC core, respectively 48 kHz, 32 kHz, 24 kHz or 16 kHz

audio super frame: audio super frame contains a number of AUs which together contain the encoded audio for 120 ms
**subchannel_index** is derived from the size of the sub-channel carrying the audio service and defines the number of Reed-Solomon code words in each audio super frame.

### 3.2 Abbreviations

For the purposes of the present document, the abbreviations given in ETSI EN 300 401 [1] and the following apply:

- **AAC** Advanced Audio Coding
- **AU** Access Unit
- **CRC** Cyclic Redundancy Check
- **CU** Capacity Unit
- **DAB** Digital Audio Broadcasting
- **DAC** Digital Analogue Converter
- **DMB** Digital Multimedia Broadcasting
- **DRC** Dynamic Range Control
- **DVB** Digital Video Broadcasting
- **FIC** Fast Information Channel
- **FIG** Fast Information Group
- **GF** Galois Field
- **HE-AAC** High Efficiency AAC
- **MCI** Multiplex Configuration Information
- **MPEG** Moving Pictures Experts Group
- **MSC** Main Service Channel
- **PAD** Programme Associated Data
- **PS** Parametric Stereo
- **RS** Reed-Solomon
- **SAC** Spatial Audio Coding
- **SBR** Spectral Band Replication

### 3.3 Arithmetic operators

- **+** addition
- **-** subtraction
- **×** multiplication
- **÷** division

\( m \text{ DIV } p \) denotes the quotient part of the division of \( m \) by \( p \) (\( m \) and \( p \) are positive integers)

\( m \text{ MOD } p \) denotes the remainder of the division of \( m \) by \( p \) (\( m \) and \( p \) are positive integers)

\[ \sum_{i=p}^{q} f(i) \] denotes the sum: \( f(p) + f(p + 1) + f(p + 2) \ldots + f(q) \)

\[ \prod_{i=p}^{q} f(i) \] denotes the product: \( f(p) \times f(p + 1) \times f(p + 2) \ldots \times f(q) \)

### 4 Introduction

The DAB system standard [1] allows audio (programme) services to be carried using either DAB audio or DAB+ audio. The present document defines the way that audio (programme) services are carried when using DAB+ audio (MPEG 4 HE-AACv2 audio coding).

MPEG 4 HE-AACv2 specifies two transforms, but only the 960 transform is permitted for DAB+ audio, with core sampling rates of 48 kHz, 32 kHz, 24 kHz and 16 kHz. Each AU (audio frame) contains samples for 20 ms, 30 ms, 40 ms or 60 ms respectively. AUs are built into audio super frames of 120 ms duration which are then carried in five DAB logical frames. In order to provide additional error control, Reed Solomon coding and virtual interleaving is applied. The overall scheme is shown in figure 1.
5 Audio

5.1 HE-AACv2 audio coding

For generic audio coding, a subset of the MPEG-4 High Efficiency Advanced Audio Coding v2 (HE-AACv2) profile chosen to best suit the DAB system environment is used. The HE-AACv2 Profile, Level 2 according to [2] shall apply with the following additional restrictions for the DAB system:

- Sampling rates: permitted output sampling rates of the HE-AACv2 decoder are 32 kHz and 48 kHz, i.e. when SBR is enabled the AAC core shall be operated at 16 kHz or 24 kHz, respectively. If SBR is disabled then the AAC core shall be operated at 32 kHz or 48 kHz respectively.
- Transform length: the number of samples per channel per AU is 960. This is required to harmonize HE-AAC AU lengths to allow the combination of an integer number of AUs to build an audio super frame of 120 ms duration.
- Audio bit rates are restricted to fit within a maximum sub-channel size of 192 kbps (approximately 175 kbps for audio, assuming no PAD).
- Audio super framing: AUs are composed into audio super frames, which always correspond to 120 ms in time. The AUs in the audio super frames are encoded together such that each audio super frame is of constant length, i.e. that bit exchange between AUs is only possible within an audio super frame. The number of AUs per super frame are: two (16 kHz AAC core sampling rate with SBR enabled), three (24 kHz AAC core sampling rate with SBR enabled), four (32 kHz AAC core sampling rate) or six (48 kHz AAC core sampling rate).

Each audio super frame is carried in five consecutive logical DAB frames (see clause 7) which enables simple synchronization and management of reconfigurations. The size of the audio super frame is defined by the size of the MSC sub-channel (see ETSI EN 300 401 [1], clause 6.2.1) which carries the audio super frame. Sub-channels are multiples of 8 kbps in size. The size of the audio super frame in bytes is given by the expressions below:

\[
\text{subchannel\_index} = \frac{\text{MSC sub-channel size (kbps)}}{8}
\]
\[
\text{audio\_super\_frame\_size (bytes)} = \text{subchannel\_index} \times 110
\]

The first byte of the audio super frame is byte 0 and the last byte is byte \((\text{audio\_super\_frame\_size} - 1)\).

**NOTE:** The subchannel_index parameter may take the values 1 to 24 due to the restriction limiting the maximum sub-channel size to 192 kbps.
5.2 Audio super framing syntax

Table 1: Syntax of he_aac_super_frame()

<table>
<thead>
<tr>
<th>Syntax</th>

<tr>
<td>for (n = 0; n &lt; num_aus; n++) {</td>
<td></td>
<td></td>
</tr>
<tr>
<td>au[n]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>au_crc[n]</td>
<td></td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>NOTE: au corresponds to one single access unit. Each au is protected by one CRC. The size of he_aac_super_frame() is equal to audio_super_frame_size.</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

he_aac_super_frame_header()

The header contains the audio parameters for the audio super frame and the respective start positions of each AU within the audio super frame, along with an error protection word. The au_start values for the second and subsequent AUs are stored consecutively in the header. Depending on the number of AUs, 4 padding bits are added to achieve byte-alignment.

num_aus

The number of AUs in the audio super frame is determined by the settings of the audio parameters. num_aus may take the values 2, 3, 4 or 6 (see table 2).

au[n]

The AU contains the audio samples for 20 ms, 30 ms, 40 ms or 60 ms of audio depending on the core sampling rate, respectively 48 kHz, 32 kHz, 24 kHz or 16 kHz.

au_size[n]

This is the size in bytes of the AU.

au_crc[n]

Each AU is protected by a 16-bit CRC.

The CRC shall be generated according to the procedure defined in ETSI EN 300 401 [1], annex E. The generation shall be based on the polynomial:

\[ G(x) = x^{16} + x^{12} + x^5 + 1 \]

The CRC word shall be complemented (1s complement) prior to transmission. At the beginning of each CRC word calculation, all register stages shall be initialized to “1”.

</tr>
<tr>
<td>if ((dac_rate == 0) &amp; (sbr_flag == 1)) num_aus = 2;</td>
<td>AAC core sampling rate 16 kHz</td>
<td></td>
</tr>
<tr>
<td>if ((dac_rate == 1) &amp; (sbr_flag == 1)) num_aus = 3;</td>
<td>AAC core sampling rate 24 kHz</td>
<td></td>
</tr>
<tr>
<td>if ((dac_rate == 0) &amp; (sbr_flag == 0)) num_aus = 4;</td>
<td>AAC core sampling rate 32 kHz</td>
<td></td>
</tr>
<tr>
<td>if ((dac_rate == 1) &amp; (sbr_flag == 0)) num_aus = 6;</td>
<td>AAC core sampling rate 48 kHz</td>
<td></td>
</tr>
<tr>
<td>for (n = 1; n &lt; num_aus; n++) {</td>
<td></td>
<td></td>
</tr>
<tr>
<td>au_start[n];</td>
<td>12</td>
<td>AU start position</td>
</tr>
<tr>
<td>}</td>
<td></td>
<td></td>
</tr>
<tr>
<td>if !((dac_rate == 1) &amp; (sbr_flag == 1))</td>
<td></td>
<td></td>
</tr>
<tr>
<td>alignment</td>
<td>4</td>
<td>byte-alignment</td>
</tr>
</tbody>
</table>

NOTE: The au_start for the first AU in the audio super frame (au_start[0]) is not transmitted. The first AU always starts immediately after the he_aac_super_frame_header().

header_firecode

The header_firecode is a 16-bit field containing a Fire code capable of detecting and correcting most single error burst of up to 6 bits. The error pattern 101111 (where "1" indicates "bit error", "0" indicates "no bit error") can be detected but not corrected. The Fire code shall be generated using the polynomial:

\[ G(x) = (x^{11} + 1)(x^5 + x^3 + x^2 + x + 1) = x^{16} + x^{14} + x^{13} + x^{12} + x^{11} + x^5 + x^3 + x^2 + x + 1 \]

The Fire code word shall be calculated over the nine bytes from byte 2 to byte 10 of the audio super frame.

NOTE 1: Except in the case where num_aus = 6, the Fire code calculation will include some bytes from the first AU.

At the beginning of each Fire code word calculation, all register stages shall be initialized to "0".

NOTE 2: Other definitions call the above code an error-correcting CRC code.

audio parameters

The audio parameters comprise the rfa, dac_rate, sbr_flag, aac_channel_mode, ps_flag and mpeg_surround_config fields.

NOTE 3: When the audio parameters are changed, some interruption to the audio output should be expected. Broadcasters should therefore plan audio parameter changes carefully.

rfa

The rfa is a 1-bit field reserved for future addition. This bit shall be set to zero for the currently specified application.
dac_rate

The dac_rate is a 1-bit field to signal the sampling rate of the DAC according to table 3.

Table 3: Definition of dac_rate

<table>
<thead>
<tr>
<th>Dac_rate</th>
<th>Meaning</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>DAC sampling rate 32 kHz</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>DAC sampling rate 48 kHz</td>
<td></td>
</tr>
</tbody>
</table>

sbr_flag

The sbr_flag is a 1-bit field to signal the use of SBR according to table 4.

Table 4: Definition of sbr_flag

<table>
<thead>
<tr>
<th>sbr_flag</th>

<td>mono refers to a single_channel_element() see [2]</td>
</tr>
<tr>
<td>1</td>
<td>AAC (core) coding is stereo</td>
<td>stereo refers to a channel_pair_element() see [2]</td>
</tr>
</tbody>
</table>

ps_flag

The ps_flag is a 1-bit field to signal the use of PS according to table 6.

Table 6: Definition of ps_flag

<table>
<thead>
<tr>
<th>ps_flag</th>
<th>Meaning</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>PS not used</td>
<td></td>
</tr>
<tr>

<td>PS used</td>
<td>only permitted when sbr_flag == 1 &amp;&amp;</td>
</tr>
<tr>
<td></td>
<td></td>
<td>aac_channel_mode == 0</td>
</tr>
</tbody>
</table>

mpeg_surround_config

The mpeg_surround_config is a 3-bit field according to table 7.

Table 7: Definition of mpeg_surround_config

<table>
<thead>
<tr>
<th>mpeg_surround_config</th>
<th>Meaning</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>000</td>
<td>MPEG Surround is not used</td>
<td></td>
</tr>
<tr>
<td>001</td>
<td>MPEG Surround with 5.1 output</td>
<td>channels is used</td>
</tr>
<tr>
<td></td>
<td>channels is used</td>
<td></td>
</tr>
<tr>
<td>010</td>
<td>MPEG Surround with 7.1 output</td>
<td>channels is used</td>
</tr>
<tr>
<td></td>
<td>channels is used</td>
<td></td>
</tr>
<tr>
<td>011 to 110</td>
<td>reserved for future definition</td>
<td></td>
</tr>
<tr>
<td>111</td>
<td>other mode (the mode can be</td>
<td>derived from the MPEG Surround</td>
</tr>
<tr>
<td></td>
<td>derived from the MPEG Surround</td>
<td>SpatialSpecificConfig())</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
The number of output channels provided by MPEG Surround is intended as an information for the listener only. The MPEG Surround decoder shall use this information only to determine whether MPEG Surround is used. If MPEG Surround is used (mpeg_surround_config ≠ 000), the MPEG Surround decoder shall exclusively rely on the information contained within the SpatialSpecificConfig().

A decoder that does not support MPEG Surround shall ignore this parameter.

au_start[n]

The au_start is an unsigned integer, most significant bit first, carried in a 12-bit field that defines the start position within the audio super frame of the respective AU by giving the byte number of the first byte of the AU. The value of au_start for the first AU is not transmitted but is given by table 8.

Table 8: Definition of au_start for the first AU of the audio super frame

<table>
<thead>
<tr>
<th>num_aus</th>
<th>value of au_start[0]</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>5</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>11</td>
<td></td>
</tr>
</tbody>
</table>

The value of au_start for subsequent AUs is given by the expressions below:

- \( au_{start}[n] = au_{start}[n - 1] + au_{size}[n - 1] + 2; \)
- \( au_{start}[num\_aus] = audio_{super\_frame\_size}. \)

The decoder can derive the value of au_size[n] from the received au_start[n] and au_start[n + 1].

alignment

This 4-bit field, when present, shall be set to 0 0 0 0.

5.3 MPEG Surround

5.3.1 Overview

MPEG Surround is standardized in MPEG-D, Part-1 (ISO/IEC 23003-1 [i.1]). It describes:

- Coding of multichannel signals based on a downmixed signal of the original multichannel signal, and associated spatial parameters. It offers lowest possible data rate for coding of multichannel signals, as well as an inherent mono or stereo downmix signal included in the data stream. Hence, a mono or stereo signal can be expanded to multi-channel by a very small additional data overhead.

- Binaural decoding of the MPEG Surround stream, enabling a surround sound experience over headphones.

- An Enhanced Matrix Mode that enables a multi-channel upmix from a stereo signal without any spatial parameters.

Hence, MPEG Surround (Spatial Audio Coding, SAC) is capable of re-creating N channels based on M < N transmitted channels, and additional control data. In the preferred modes of operating the spatial audio coding system, the M channels can either be a single mono channel or a stereo channel pair. The control data represents a significantly lower data rate than required for transmitting all N channels, making the coding very efficient while at the same time ensuring compatibility with both M channel devices and N channel devices.

The MPEG Surround standard incorporates a number of tools that provide features which enable broad application of the standard. A key feature is the ability to scale the spatial image quality gradually from very low spatial overhead towards transparency. Another key feature is that the decoder input can be made compatible to existing matrix surround technologies. All tools are grouped to be covered by certain profiles.
Receivers with a different number of output channels than the number of MPEG Surround target channels may still render the multichannel audio signal according to the available number of output channels (possibly at a reduced quality compared to the case where the number of target channels matches the number of output channels).

5.3.2 Requirements for MPEG Surround encoders and decoders

The support of MPEG surround is optional for both audio encoder and decoder.

Interoperability between the different possible configurations for MPEG Surround is assured by MPEG profiles and levels. All subsequent statements towards profiles and levels refer to the definitions stated in ISO/IEC 23003-1 [i.1].

Table 9 defines the requirements for MPEG Surround encoders and decoders in order to support MPEG Surround.

<table>
<thead>
<tr>
<th>Requirements for MPEG Surround encoder</th>
<th>Requirements for MPEG Surround decoder</th>
</tr>
</thead>
<tbody>
<tr>
<td>The MPEG Surround encoder shall comply to the Baseline MPEG Surround profile. The used MPEG Surround bitstream tree config shall be mono or stereo based. See note. The spatial data shall be embedded in the downmix data stream, i.e. in the MPEG-4 AAC payload.</td>
<td>The decoder shall support at least level 1 of the Baseline MPEG Surround profile.</td>
</tr>
<tr>
<td>NOTE: The audio core permits mono or stereo only. The maximum sampling rate is 48 kHz.</td>
<td></td>
</tr>
</tbody>
</table>

5.3.3 Operational aspects of broadcasting

It is not mandated that MPEG Surround is used for the whole lifetime of the service component.

The parameter mpeg_surround_config of the DAB+ audio super frame header shall indicate whether MPEG Surround is used. Enabling/disabling of MPEG Surround as well as changes to the MPEG Surround configuration shall only be made at DAB+ audio super frame boundaries.

When MPEG Surround is used, all audio access units shall contain an extension payload of type EXT_SAC_DATA and the SpatialSpecificConfig() shall be broadcast at least every fourth audio super frame (i.e. every 480 ms). The IndependentFlag within the SpatialSpecificConfig() shall be set in at least every fourth audio super frame (i.e. every 480 ms).

EXT_SAC_DATA payloads shall be broadcast only when MPEG Surround is used.

When MPEG Surround is enabled or its configuration is changed, the first audio access unit of the new configuration shall contain the SpatialSpecificConfig() to allow seamless continuation of audio playback.

Changes of the MPEG Surround configuration shall not happen more frequently than every fourth DAB+ audio super frames (i.e. 480 ms).

NOTE: It is assumed that an MPEG Surround configuration is valid for the entirety of a programme item.

5.3.4 Receiver implementation aspects

A receiver that is capable of decoding MPEG Surround shall probe each DAB+ audio super frame header for the parameter mpeg_surround_config. If MPEG Surround is used, the receiver shall be prepared to decode MPEG Surround.

If EXT_SAC_DATA extension payloads are received, an MPEG Surround capable receiver shall not delay playback (i.e. it shall not hold back playing) for more than four DAB+ audio super frames (i.e. 480 ms). If it has not received a SpatialSpecificConfig() by then, it shall start decoding and playback of the HE-AACv2 payload, but shall continuously check for the availability of a SpatialSpecificConfig() and then reconfigure itself for the decoding of MPEG Surround.
It is not mandated that an MPEG Surround payload is transmitted for the whole lifetime of the service component and hence a receiver shall support a change of the MPEG Surround configuration. Depending on the implementation, this may result in a receiver that can reconfigure the audio output or a receiver that always produces multichannel sound output. In the latter case, the MPEG Surround enhanced matrix mode can be used to generate the multichannel output if no MPEG Surround payload is transmitted.

If a receiver is currently decoding MPEG Surround and the parameter mpeg_surround_config indicates that MPEG Surround is no longer used or if an audio access unit with no EXT_SAC_DATA extension payload is received, then the receiver shall assume that MPEG Surround is no longer used and appropriately reconfigure itself.

A receiver shall assume that each reconfiguration is valid at least for the equivalent of four DAB+ audio super frames (480 ms) output audio data, hence it shall not reconfigure itself more than about two times per second.

The receiver shall be able to detect and correctly handle changes in the SpatialSpecificConfig().

5.4 Programme Associated Data (PAD)

5.4.0 Introduction

Each AU may include a number of bytes that carry Programme Associated Data (PAD). PAD is information that is synchronous to the audio and its contents may be intimately related to the audio. The PAD bytes in successive AUs constitute the PAD channel. The PAD is coded according to ETSI EN 300 401 [1], clause 7.4, using the F-PAD and X-PAD.

In each PAD field there may be two bytes called the fixed PAD (F-PAD). The F-PAD field is intended to carry control information with a strong real-time character and data with a very low bit rate. The PAD channel may be extended using an Extended PAD (X-PAD) field, intended to carry information providing additional functions to the listener, such as programme related text. The length of the X-PAD field is chosen by the service provider.

The inclusion of PAD is optional for the service provider.

The PAD bytes (if present) are always stored in a data_stream_element(), being a syntactic element of AAC [2] that can be multiplexed within a raw_data_block().

5.4.1 PAD insertion

Figure 2 shows the coding of the F-PAD and X-PAD fields within the PAD field.

![Figure 2: Coding of the PAD field](image)

If no information is available for the X-PAD field and no information is sent in the F-PAD field, then the PAD field is empty and shall not be added to the AU.

If information is available for the X-PAD field but no information is sent in the F-PAD field, then both bytes of the F-PAD field shall be set to zero.

If no information is available for the X-PAD field but information is sent in the F-PAD field, then the PAD field only contains the F-PAD.

The PAD field carried in au[n] shall be associated with the audio carried in the following AU, au[n + 1].

All bytes of the PAD field have the same error protection. The maximum size of the X-PAD field is 196 bytes.
Table 10: Maximum bit rate of F-PAD and X-PAD data

<table>
<thead>
<tr>
<th>AAC core sampling rate</th>
<th>Maximum bit rate for F-PAD data (2 bytes)</th>
<th>Maximum bit rate for X-PAD data (196 bytes)</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>48 kHz</td>
<td>800 bps</td>
<td>78 400 bps</td>
</tr>
</tbody>
</table>

The data_stream_element() carrying the PAD data shall be the first syntactic element of the raw_data_block().

The element_instance_tag of the data_stream_element() shall be the same as the element_instance_tag of the accompanied single_channel_element() or channel_pair_element(). Embedding a PAD field into a data_stream_element() causes an overhead of 2 bytes. There will be at most one data_stream_element() used for PAD insertion per raw_data_block().

The F-PAD channel carries a 2-bit field, "X-PAD Ind", which indicates one of three possibilities for the length of the X-PAD field:

- No X-PAD: only the F-PAD field is available. No X-PAD field is present. The length of the PAD field shall be two bytes.
- Short X-PAD: in this case the length of the X-PAD field in the current AU is four bytes. The length of the PAD field is 6 bytes.
- Variable size X-PAD: in this case the length of the X-PAD field may vary from AU to AU. The length of the X-PAD field in the current access unit can be derived by subtracting the length of the F-PAD field (2 bytes) from the length of the complete PAD field.

5.4.2 Coding of F-PAD and X-PAD

The coding of F-PAD and X-PAD shall be as specified in ETSI EN 300 401 [1], clause 7.4.

Dynamic Range Control (DRC) data for DAB+ audio shall not be carried in F-PAD. If dynamic range control is used, the DRC data shall be encoded utilizing AAC specific means: DRC data is stored in dynamic_range_info(), being contained in an extension_payload(), which in turn is contained in a fill_element(), the latter being a syntactic element of AAC that can be multiplexed within a raw_data_block().

NOTE: For DAB audio, Dynamic Range Control (DRC) provides a single value that adjusts the amplifier gain for all audio channels within a range between 0 dB and +15,75 dB. A similar functionality is provided for DAB+ audio by means of the DRC parameters "dyn_rng_ctl" and "dyn_rng_sgn". Those permit to set the amplifier gain in the range -31,75 dB to +31,75 dB. So as to be compliant to the DRC definition of HE-AACv2, a DAB+ audio decoder that supports DRC supports the full DRC functionality defined for HE-AACv2.

A DAB+ encoder that supports DRC shall always write "0" into the DRC data field "pce_tag_present".

A DAB+ decoder that supports DRC shall be able to parse the dynamic_range_info() even if "pce_tag_present" is "1", but shall ignore the value in the then transmitted data field "pce_instance_tag".

5.4.3 PAD extraction

PAD data (if present) is always located at the beginning of an AU; therefore if the AU starts with a data_stream_element(), then PAD data is available.

If no data_stream_element() is present at the beginning of the AU, or if the length of the data_stream_element() is less than two bytes (i.e. an invalid length for PAD data), then the PAD decoder shall react as if the F-PAD field had been received with both bytes set to zero and no X-PAD data is available.

The data_stream_element() explicitly indicates the length of the PAD information. The PAD decoder uses this length information to determine the size of the PAD field and also the size of the X-PAD field (if present). The size of the X-PAD field (if present) is two bytes less than the size of the PAD field.
Once the X-PAD field is extracted, decoding is the same as for X-PAD in MPEG audio layer II. The length of the X-PAD shall also be deduced from the contents information carried within the X-PAD field. If this length does not match the length of the X-PAD field derived from the length information within the data_stream_element(), then the decoder shall discard the X-PAD field.

6 Transport error coding and interleaving

6.0 Introduction

Audio super frames are transported in five successive DAB logical frames with additional error protection. Reed-Solomon coding and byte-wise virtual interleaving are employed to increase the reliability of audio decoding in receivers.

The virtual interleaver can be considered as an array of dimensions $\text{subchannel\_index}$ rows by 120 columns. The $\text{subchannel\_index}$ is equal to the number of RS packets required to carry the audio super frame. The audio super frame data is fed into the table starting with the first row and first column and filling byte by byte from top to bottom and from left to right until the first 110 columns are completely filled. The RS parity bytes are then calculated across the rows, filling the final 10 columns. The table is transmitted, starting with the first row and first column and transmitting byte by byte from top to bottom and from left to right until all 120 columns have been sent.

In this way, the audio super frame data is transmitted in its original byte order, but the RS parity codewords are calculated from interleaved data. This increases the likelihood that any error bursts that overload the error protection scheme will only destroy one AU, rather than many.

6.1 RS coding

Reed-Solomon RS(120, 110, $t = 5$) shortened code (see note 1), derived from the original systematic RS(255, 245, $t = 5$) code, shall be applied to 110 byte portions of each audio super frame to generate an error protected packet (see figure 3).

NOTE 1: The Reed-Solomon code has length 120 bytes, dimension 110 bytes and allows the correction of up to 5 random erroneous bytes in a received word of 120 bytes.

Code generator polynomial: $G(x) = \prod_{i=0}^{9} (x + \alpha^i)$

Galois Field GF($2^8$) with $\alpha^1 = 2$ using polynomial: $P(x) = x^8 + x^4 + x^3 + x^2 + 1$

NOTE 2: The Galois Field used is the same as is already used in the DMB and DVB specifications, thus allowing the same Galois Field arithmetic blocks to be used, however the code polynomial is shorter due to the fact that $t = 5$ in this implementation but $t = 8$ in the DMB/DVB specifications.

The shortened Reed-Solomon code may be implemented by adding 135 bytes, all set to zero, before the information bytes at the input of an RS(255, 245, $t = 5$) encoder. After the RS coding procedure these null bytes shall be discarded, leading to a RS code word of N = 120 bytes.

![Figure 3: Error protected packet](image-url)
6.2 Formation of the coding array

The elements of the coding array, \( C_{(i, (s - 1))\times[0..109]} \), shall be filled by the audio super frame bytes, \( A_{(0..(110 \times s) - 1)} \). The position of bytes in the coding array, \( C \), is defined by:

\[
C_{i,j} = A_{i \times j
}
\]

where:
- \( C_{i,j} \) shall be the elements of \( C \) with row index \( i \ [0..(s - 1)] \) and column index \( j \ [0..109] \);
- \( s \) shall be the subchannel_index.

6.3 Formation of the parity array

The elements of the parity array, \( P_{i,[0..9]} \), shall be the 10 parity check bytes calculated for the information bytes \( C_{i,[0..109]} \), where \( i \) is in the range 0 to \( (s - 1) \). The check bytes shall be calculated using the RS(120, 110, \( t = 5 \)) code described in clause 6.1.

6.4 Formation of the output array

The elements of the output array, \( O_{(0..(120 \times s) - 1)} \), shall be filled by the audio super frame bytes, \( A_{(0..(110 \times s) - 1)} \) and the error protection bytes \( P_{(0..(s - 1)))\times[0..9]} \).

The position of bytes in the output array, \( O \), is defined by:

\[
O_k = \begin{cases} 
A_k & 0 \leq k < 110 \times s \\
P_{q,r} & 110 \times s \leq k < 120 \times s
\end{cases}
\]

where:
- \( A_k \) shall be the elements of \( A \) with index \( k \ [0..(110 \times s) - 1] \);
- \( P_{q,r} \) shall be the elements of \( P \) with row index \( q = k \ MOD \ s \) and column index \( r = (k \ DIV \ s) - 110 \);
- \( k \) shall be the index \([0..(120 \times s) - 1]\) of the output array.

6.5 Order of data transmission

Data shall be transmitted by reading out the elements of the output array \( O_{(0..(120 \times s) - 1)} \). The bytes shall be read in sequence starting with \( O_0 \).

7 Signalling

7.1 FIC signalling

DAB+ audio services are signalled by setting the ASCTy carried in FIG 0/2 (see ETSI EN 300 401 [1], clause 6.3.1) to the appropriate value.

7.2 Audio parameter signalling

Audio parameters are signalled in the audio super frame header, see clause 5.2.
8 Reconfiguration

Reconfiguration of the DAB multiplex may take place to allow new services to begin broadcasting, others to cease (either temporarily or permanently) or capacity to be exchanged between services (see ETSI EN 300 401 [1], clause 6.5). Reconfiguration of a sub-channel carrying a DAB+ audio service shall only take place at an audio super frame boundary. For a sub-channel that is reduced in capacity, the change will take place three audio super frames (15 logical frames) before the reconfiguration instant. For a sub-channel that remains the same size (for example, by changing CU start address or exchanging bit-rate and protection level) or a sub-channel that is increased in capacity, the change will take place at the reconfiguration instant.

NOTE 1: It is recommended that a multiplex containing DAB+ audio services is managed such that the audio super frames of all DAB+ audio services are aligned to ease the reconfiguration process.

A reconfiguration is only signalled when the sub-channel and/or service parameters of the MCI are changed. A change of the audio parameters signalled in the audio super frame header, which does not cause a change to the MCI, is not signalled as a reconfiguration.

NOTE 2: When the audio parameters are changed, some interruption to the audio output should be expected. Broadcasters should therefore plan audio parameter changes carefully.
Annex A (normative):
Error concealment

A.0 Introduction

For the AAC core decoder and for the SBR and PS tools a description for concealment of erroneous bit streams is given. The error concealment provided by the DAB HE-AACv2 decoder shall provide at least the same level of performance as specified in this annex, but may be enhanced by specific implementations.

Concealment is applied when the transport layer indicates a distorted AU, i.e. the au_crc fails. If the he_aac_super_frame_header parameters cannot be correctly recovered, then the boundaries between AUs may be unavailable and one or more au_crcs may not be able to be determined. In this case concealment is applied to all affected AUs in the audio super frame. There are also various tests (plausibility checks) inside the AAC decoder and the SBR and PS tools. If such a check indicates an invalid bit stream, then concealment is applied to the according decoder stage, too.

A.1 AAC error concealment

A.1.0 Introduction

The AAC core decoder includes a concealment function that increases the delay of the decoder by one AU.

Concealment works on the spectral data just before the final frequency to time conversion. In case a single AU is corrupted, concealment interpolates between the preceding and the following valid AUs to create the spectral data for the missing AU. If multiple AUs are corrupted, concealment implements first a fade out based on slightly modified spectral values from the last valid AU. If the decoder recovers from the error condition, the concealment algorithm performs a fade-in on valid spectral values. Fade in might be delayed (suppressed) to deal with error conditions, where only a valid AU here and there is perceived.

A.1.1 Interpolation of one corrupt AU

In the following, the actual AU is \( au[n] \), the corrupt AU to be interpolated is \( au[n-1] \) and the last but one AU is \( au[n-2] \). \( au[n-2] \) is the preceding valid AU for which spectral values have been stored during the processing in the previous call to the decoder.

The determination of window sequence and the window shape of the corrupt AU are described in table A.1.

<table>
<thead>
<tr>
<th>window sequence ( n-2 )</th>
<th>window sequence ( n )</th>
<th>window sequence ( n-1 )</th>
<th>window shape ( n-1 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>ONLY_LONG_SEQUENCE or LONG_START_SEQUENCE or LONG_STOP_SEQUENCE</td>
<td>ONLY_LONG_SEQUENCE or LONG_START_SEQUENCE or LONG_STOP_SEQUENCE</td>
<td>ONLY_LONG_SEQUENCE</td>
<td>0</td>
</tr>
<tr>
<td>ONLY_LONG_SEQUENCE or LONG_START_SEQUENCE or LONG_STOP_SEQUENCE</td>
<td>EIGHT_SHORT_SEQUENCE</td>
<td>LONG_START_SEQUENCE</td>
<td>1</td>
</tr>
<tr>
<td>EIGHT_SHORT_SEQUENCE</td>
<td>EIGHT_SHORT_SEQUENCE</td>
<td>EIGHT_SHORT_SEQUENCE</td>
<td>1</td>
</tr>
<tr>
<td>EIGHT_SHORT_SEQUENCE</td>
<td>ONLY_LONGSEQUENCE or LONG_START_SEQUENCE or LONG_STOP_SEQUENCE</td>
<td>LONG_STOP_SEQUENCE</td>
<td>0</td>
</tr>
</tbody>
</table>
The scalefactor band energies of au[n - 2] and au[n] are calculated. If the window sequence in one of these AUs is an EIGHT_SHORT_SEQUENCE and the final window sequence for au[n - 1] is one of the long transform windows, the scalefactor band energies are calculated for long block scalefactor bands by mapping the frequency line index of short block spectral coefficients to a long block representation. The new interpolated spectrum is built on a per-scalefactorband basis by reusing the spectrum of the older AU, au[n - 2] and multiplying a factor to each spectral coefficient. An exception is made in the case of a short window sequence in au[n - 2] and a long window sequence in au[n]; here the spectrum of au[n] is modified by the interpolation factor. This factor is constant over the range of each scalefactor band and is derived from the scalefactor band energy differences of au[n - 2] and au[n]. Finally noise substitution is applied by flipping the sign of the interpolated spectral coefficients randomly.

A.1.2 Fade-out and fade-in
Fade-out and fade-in behaviour, i.e. the attenuation ramp, might be fixed or adjustable by the user. The spectral coefficients from the last AU are attenuated by a factor corresponding to the fade-out characteristics and then passed to the frequency-to-time mapping. Depending on the attenuation ramp, the concealment switches to muting after a number of consecutive invalid AUs, which means the complete spectrum will be set to 0.

After recovering from the error condition, the decoder fades in again depending on a ramp-up function possibly different from the ramp-down characteristics. If the concealment has switched to muting, fade-in might be suppressed for a configurable number of AUs to avoid annoying output of non-consecutive individual valid AUs.

A.2 SBR error concealment
The SBR error concealment algorithm is based on using previous envelope and noise-floor values with an applied decay, as a substitute for the corrupt data. In the flowchart of figure 1 the basic operation of the SBR error concealment algorithm is outlined. If the AU error flag is set, error concealment bitstream data is generated to be used instead of the corrupt bitstream data. The concealment data is generated according to the following:

The time frequency grids are set to:

- \( L_k = 1 \)
- \( t_k(0) = t'_k (L'_k) - \text{numTimeSlots} \)
- \( t_k(1) = \text{numTimeSlots} \)
- \( r(l) = \text{HI} \), \( 0 \leq l < L_k \)
- \( \text{bs\_pointer} = 0 \)
- \( L_q = 1 \)
- \( t_q = [t_k(0), t_k(1)] \)

The delta coding direction for both the envelope data and noise-floor data are set to be in the time-direction. The envelope data is calculated according to:

\[
E_{d_{env}}(k,l) = \begin{cases} 
-\text{step} & \text{if } E_{prev}(k,l) > \text{target} \\
\text{step} & \text{otherwise} \\
\end{cases}, 0 \leq k < n(r(l)), 0 \leq l < L_k
\]

where:

\[
\text{step} = \begin{cases} 
2 & \text{if } \text{bs\_amp\_res} = 1 \\
1 & \text{otherwise} \\
\end{cases}
\]
And where `bs_amp_res` and `bs_coupling` are set to the values of the previous AU.

The noise floor data is calculated according to:

\[
Q_{\text{delta}}(k,l) = \begin{cases} 
0, & 0 \leq l < L_Q \\
\leq N_Q 
\end{cases}
\]

Furthermore, the inverse-filtering levels in `bs_invf_mode` are set to the values of the previous AU, and all elements in `bs_add_harmonic` are set to zero.

If the AU error flag is not set, the present time grid and envelope data may need modification if the previous AU was corrupt. If the previous AU was corrupt, the time grid of the present AU is modified in order to make sure that there is a continuous transition between the AUs. The envelope data for the first envelope is modified according to:

\[
E_{\text{mod}}(k,0) = E(k,0) + a \cdot \log \left( \frac{t_{E}(1) - t_{E}(0)}{t_{E}(1) - \text{estimated}_\text{start}_\text{pos}} \right), \quad 0 \leq k < \mathbf{F}(r(l),0)
\]

where:

\[
\text{estimated}_\text{start}_\text{pos} = t_{E}'(L_{E}') - \text{numberTimeSlots}
\]

After the delta coded data has been decoded, a plausibility check is performed to make sure that the decoded data is within reasonable limits. For the envelope data, the logarithmic values shall be within the limits:

\[
E(k,l) \leq \begin{cases} 
35, & \text{ampRes} = 0 \\
70, & \text{ampRes} = 1
\end{cases}
\]

Otherwise the AU will be considered corrupt.

The time grids are also verified according to the following rules (if any of the below is true the AU is considered to be corrupt):

- \( L_E < 1 \)
- \( L_E > 5 \)
- \( L_Q > 2 \)
- \( t_E(0) < 0 \)
- \( t_E(0) \geq t_E(L_E) \)
- \( t_E(0) > 3 \)
- \( t_E(L_E) < 16 \)
- \( t_E(L_E) > 19 \)
- \( t_E(l) \geq t_E(l+1), 0 \leq l < L_E \)
- \( l_A > L_E \)
- \( L_E = 1 \text{ AND } L_Q > 1 \)
• \( t_Q(0) \neq t_E(0) \)
• \( t_Q(L_Q) \neq t_E(L_E) \)
• \( t_Q(I) \geq t_Q(I+1), 0 \leq I < L_Q \)
• all elements of \( t_Q \) are not among the elements of \( t_E \)

If the plausibility check fails, the AU error flag is set and the error concealment outlined above is applied.

![Figure A.1: SBR error concealment overview](image)

### A.3 Parametric stereo error concealment

Parametric stereo error concealment is based on the fact that the stereo image is quasi stationary. The concealment strategy keeps the Parametric Stereo settings from the last valid AU until a new set of Parametric Stereo settings can be decoded from a valid AU.

### A.4 MPEG Surround error concealment

MPEG Surround error concealment is based on the fact that the surround image is quasi stationary. The concealment strategy keeps the MPEG Surround settings from the last valid AU until a new set of MPEG Surround settings can be decoded from a valid AU.
Annex B (informative):
Implementation tips for PAD insertion

To reduce the data rate needed for PAD, the following optimizations on encoder side should be made:

- If no PAD is inserted (neither F-PAD, nor X-PAD information is available), then no data_stream_element() encapsulating the PAD data should be added to the access unit. A value of 0 for the F-PAD field is equivalent to "no F-PAD information is available".

For low audio bit rates, it is important to take into account that additional (X-)PAD data will reduce the bit rate for the audio and thus the audio quality. For low audio bit rates, even the bit rate for dynamic labels might become significant. It is not just the average (X-)PAD data rate that should be taken into account, but especially for low audio bit rates, also the "burstiness" of (X-)PAD data insertion should be taken into consideration.

If the exact timing for X-PAD insertion is not important (it is not important for most multimedia information such as dynamic labels) and low audio bit rates are used, then the following should be considered:

- The bit rate used for PAD depends on the total number of used bytes (including encapsulation and F-PAD) per audio super frame. It might sometimes be more efficient to use one single big X-PAD field in one audio super frame than to use multiple smaller X-PAD fields in the same audio super frame.

- Some multimedia data is broadcast in bursts (e.g. if one dynamic label with title/artist information is broadcast every 15 seconds). The impact on the audio quality is reduced if such a burst is spread over multiple audio super frames instead of just one (e.g. a label of 32 bytes could be broadcast within one audio super frame or spread over 4 audio super frames with only about one fourth of the X-PAD capacity used per audio super frame).
Annex C (informative):
Synchronizing to the audio super frame structure

Before the receiver can decode an audio super frame, it first concatenates five consecutive DAB frames to build the audio super frame. The receiver needs a mechanism to be able to determine which five consecutive DAB frames within a sub channel constitute an audio super frame.

Synchronization is needed when the receiver switches to an audio sub-channel, or when the receiver detects a loss of synchronization (i.e. too many consecutive audio super frames with uncorrectable errors in the audio super frame header).

This synchronization process should be fast and reliable. Reliability also implies that the receiver is able to synchronize to the audio super frame structure even in the presence of reception errors.

The synchronization comprises multiple steps:

1) At least 5 DAB frames are stored one after the other into the audio super frame buffer. This step takes \( d \times 24 \text{ ms} \), where \( d \) is the number of DAB frames that are added to the audio super frame buffer. \( d \) is at least 5, so this step takes at least 120 ms.

2) A first test is used to check if the first DAB frame in the audio super frame buffer might be the beginning of an audio super frame. If that is not the case, go to step 4.

3) It is checked whether the first five DAB frames are a valid audio super frame (i.e. the first DAB frame contains a valid audio super frame header). The receiver does the RS decoding to correct all reception errors (if there were any) and then checks whether the header checksum is correct; for this test, the Fire code is used for error detection only. If that is the case, then the first valid audio super frame was received. Synchronization is completed.

4) If the first DAB frame of the audio super frame buffer is not a valid beginning of an audio super frame, then the first DAB frame is removed from the audio super frame buffer and the next received DAB frame is added to the end of the audio super frame buffer. DAB frames are received every 24 ms. Go to step 2.

Fast synchronization implies that the check for a valid audio super frame (step 2 and 3) can be made every 24 ms (i.e. for every received DAB frame it is possible to check whether it could be the beginning of an audio super frame). This is needed to ensure that the synchronization process is able to synchronize to the first occurrence of an audio super frame.

Depending on the receiver implementation, step 3 may be time consuming. If the time to check for a valid audio super frame (including the RS decoding) is longer than 24 ms (the time when the next DAB frame is received), then step 2 is needed to make a fast prefiltering. The time consuming step 3 is then only needed when the first DAB frame in the audio super frame buffer is very likely the beginning of an audio super frame.

Step 2 could use the Fire code in error detection mode in order to check for a valid audio super frame header even in the presence of errors in the super frame header. If the Fire code detects too many errors (i.e. more errors that it could correct), then the first DAB frame probably does not contain the beginning of an audio super frame.

NOTE 1: This check will detect all audio super frame headers with no errors or an error burst of up to 6 bits, however, it might sometimes wrongly assume to have found a valid super frame header. But still the use of the Fire code reduces the number of frames that the time consuming step 3 needs to test.

NOTE 2: This check will not detect an audio super frame header with more errors than the Fire code could correct. In such a case, the synchronization is delayed by one audio super frame (120 ms). This happens even if RS decoding (step 3) is able to correct the errors in the super frame header.

Step 2 could do the RS decoding progressively. It would use \( d = 5 \) for step 1. It would first decode just the RS codewords that protect (among other bytes) the first 11 bytes of the audio super frame, these 11 bytes are protected by the super frame header Fire code.

NOTE 3: For bitrates below 96 kbps this already implies that all RS codewords are decoded, so this optimization step only makes sense for higher bit rates.
In the next step the Fire code is used to check whether a valid audio super frame header is present at the beginning of the potential audio super frame. For this check, the Fire code is used for error detection only.

If a receiver has hardware RS decoding and step 3 is very fast (i.e. fast enough to do the RS decoding and checking for a valid audio super frame in less than 24 ms), then the receiver should use d = 5 for step 1 and check for a valid audio super frame every 24 ms (i.e. every time a DAB frame is received). Step 2 would not be used. This assures a fast and very reliable synchronization.
Annex D (informative):
Processing a super frame

Once synchronization to the audio super frame structure is achieved (see annex C), the decoder will process super frame after super frame.

The following steps will be performed:

1) First the RS decoding of the super frame is performed. Usually it will be possible to correct all reception errors (if any).

2) Then the Fire code is used (error detection only) to check if there are errors in the super frame header. If there are errors, a single burst error of up to 6 bits can be corrected by the Fire code (error correction mode).

3) If the RS decoding indicates no errors or a correctable number of errors and the Fire code (error detection mode) detects no error then it is safe to extract the audio parameters from the current audio super frame. These audio parameters are then stored.

4) If either RS or Fire code (error detection mode) indicate uncorrectable errors, then the receiver should not extract the audio parameters from the current audio super frame, but use the audio parameters extracted from an audio super frame where the RS decoding indicated no error or a correctable number of errors and the Fire code (error detection mode) indicated no error (i.e. the receiver assumes that the audio parameters are unchanged).

5) The audio parameters are evaluated to determine the number of AUs per audio super frame and the configuration of the audio decoder and the DAC.

6) If the Fire code (error detection mode) detected an error in the super frame header, then the error correction capability of the Fire code may be used to try correcting an error burst of up to 6 bits in the super frame header. At this stage, additional information from the RS decoding process may be evaluated (e.g. if one RS codeword contained uncorrectable errors, but all other RS codewords could be corrected, then this information may be used by the Fire code decoder).

The decoder then iterates over the au_start parameters. The first AU starts immediately after the super frame header; the last AU ends at the super frame end.

For all au_start values, the decoder first does a sanity check. All au_start values will be between au_start[0] and audio_super_frame_size.

To extract au[n], both au_start[n] and au_start[n + 1] will have passed the sanity check; au_start[n] also needs to be smaller than au_start[n + 1].

NOTE: A corrupted au_start value will cause the loss of two adjacent AUs.

From au_start[n] and au_start[n + 1] the decoder derives offset and length of the AU within the audio super frame. Then the au_crc is checked. If the CRC check detects an error, then the AU is concealed. If the CRC is correct, then the AU is decoded, see annex A.

If too many consecutive AUs need concealment, then the decoder will assume a synchronization loss and restart the synchronization process, see annex C.
Annex E (informative):
Bit-rate available for audio

The capacity available for audio (including PAD) is tabulated in table E.1 for reference.
