Intellectual Property Rights

Essential patents

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "*Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards*", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<https://ipr.etsi.org/>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Trademarks

The present document may include trademarks and/or tradenames which are asserted and/or registered by their owners. ETSI claims no ownership of these except for any which are indicated as being the property of ETSI, and conveys no right to use or reproduce any trademark and/or tradename. Mention of those trademarks in the present document does not constitute an endorsement by ETSI of products, services or organizations associated with those trademarks.

Foreword

This Technical Specification (TS) has been produced by ETSI Technical Committee Speech and multimedia Transmission Quality (STQ).

Modal verbs terminology

In the present document "**shall**", "**shall not**", "**should**", "**should not**", "**may**", "**need not**", "**will**", "**will not**", "**can**" and "**cannot**" are to be interpreted as described in clause 3.2 of the [ETSI Drafting Rules](#) (Verbal forms for the expression of provisions).

"**must**" and "**must not**" are **NOT** allowed in ETSI deliverables except when used in direct citation.

Introduction

The present document covers wireless speech terminals. It aims to enhance the interoperability and end-to-end quality with all other types of terminals.

The advanced signal processing of terminals is targeted to speech signals. Therefore, wherever possible speech signals are used for testing in order to archive mostly realistic test conditions and meaningful results.

1 Scope

The present document provides speech transmission performance requirements for wireless terminals; it addresses all types of wireless terminals, including softphones. The present document addresses handsfree function of wide band wireless terminals.

In contrast to other standards which define minimum performance requirements it is the intention of the present document to specify terminal equipment requirements which enable manufacturers and service providers to enable good quality end-to-end speech performance as perceived by the user whatever be the radio link (terminals may implement different radio links with the access network).

When an additional radio link between the terminal and external electroacoustical devices is used (e.g. Bluetooth® link), the present document will address the overall quality.

In the present document objective measurement methodologies and requirements for wireless speech terminals are given.

In addition to basic testing procedures, the present document describes advanced testing procedures taking into account further quality parameters as perceived by the user.

The requirements available in the present document will ensure a high compatibility across access networks with all types of terminals.

It is the aim to optimize the listening and talking quality, conversational performance, as well as the use in noisy environment. Related requirements and test methods will be defined in the present document.

For all the functions, the present document will consider the limitations in audio performance due to different form factors (e.g. size, shape).

Terminals which are not intended to be connected to public networks are outside the scope of the present document.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

artificial ear: device for the calibration of earphones incorporating an acoustic coupler and a calibrated microphone for the measurement of the sound pressure and having an overall acoustic impedance similar to that of the median adult human ear over a given frequency band

codec: combination of an analogue-to-digital encoder and a digital-to-analogue decoder operating in opposite directions of transmission in the same equipment

freefield equalization: artificial head equalized for frontal sound incidence in anechoic conditions

freefield reference point: point located in the free sound field, at least in 1,5 m distance from a sound source radiating in free air (in case of a head and torso simulator [HATS] in the center of the artificial head with no artificial head present)

handsfree telephony terminal: telephony terminal using a loudspeaker associated with an amplifier as a telephone receiver and which can be used without a handset

Head And Torso Simulator (HATS) for telephonometry: manikin extending downward from the top of the head to the waist, designed to simulate the sound pick-up characteristics and the acoustic diffraction produced by a median human adult and to reproduce the acoustic field generated by the human mouth

Mouth Reference Point (MRP): is located on axis and 25 mm in front of the lip plane of a mouth simulator

nominal setting of the volume control: when a receive volume control is provided, the setting which is closest to the nominal RLR

softphone: speech communication system based upon a computer

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

a.c.	alternative current
AM - FM	Amplitude and Frequency Modulated
AMR-WB	Adaptive MultiRate codec - Wideband
CDMA	Code Division Multiple Access

CS	Composite Source
CSS	Composite Source Signal
DECT	Digital Enhanced Cordless Telecommunications
DFT	Discrete Fourier Transformation
DRP	ear Drum Reference Point
DUT	Device Under Test
EL	Echo Loss
EVS	Enhanced Voice Services
FFT	Fast Fourier Transformation
G-MOS-LQOw	Overall transmission quality for wideband systems
GSM	Global System for Mobile telecommunication
HATS	Head And Torso Simulator
HF	Hands-Free
HFRP	Hands Free Reference Point
HFT	Hands-Free Terminal
LTE	Long Term Evolution (3GPP)

NOTE: See Recommendation ITU-T P.79 [9].

MOS	Mean Opinion Score
MOS-LQOy	Mean Opinion Score - Listening Quality Objective
MRP	Mouth Reference Point

NOTE: See Recommendation ITU-T P.800.1 [i.3].

NLP	Non Linear Processor
N-MOS-LQOw	Transmission quality of the background noise for wideband systems
OTT	Over The Top solutions
PDA	Personal Digital Assistant
PN	Pseudo Noise
POI	Point Of Interconnect
QoS	Quality of Service
RF	Radio Frequency
RLR	Receive Loudness Rating
SLR	Send Loudness Rating
S-MOS-LQOw	Transmission quality of the speech for wideband systems
TCL	Terminal Coupling Loss
TCLw	Terminal Coupling Loss (weighted)
TELR	Talker Echo Loudness Rating
TOSQA	Telecom Objective Speech Quality Assessment
UE	User Equipment
UMTS	Universal Mobile Telecommunications System
VoLTE	Voice over LTE
WIFI	Wireless Fidelity
WIMAX™	Worldwide Interoperability for Microwave ACCess

NOTE: It is a Trademark.

4 Configurations and interfaces

4.0 Introduction

The present document is intended to be applicable for different wireless access networks and for additional radio links.

4.1 Access networks

The present document applies to any wireless terminal whatever the access network, e.g. GSM, UMTS, VoLTE, DECT, Bluetooth®, WIFI, WIMAX™, CDMA, etc.

4.2 Additional (radio) links between the terminal and external electroacoustical devices

The present document also applies when an additional radio link exists between the wireless terminal and external electro acoustic devices, e.g. Bluetooth.

5 Test Configurations

5.1 Set-up interface

The generic schematic is applicable to any wireless link.

NOTE: The "whole" terminal includes all the components from "RF interface" to the transducers and may include an additional (radio) link. The air interface considered in the figure is not the additional radio link.

Figure 5.1: Set-up interface

5.2 Set-up for terminals

5.2.0 Introduction

For electroacoustical testing, HATS as described in Recommendation ITU-T P.58 [8] shall be used.

The preferred way of testing a terminal is to connect it to a network simulator with exact defined settings and access points. The test sequences are fed in either electrically, using a reference codec or using the direct signal processing approach or acoustically using ITU-T specified devices.

When a coder with variable bit rate is used for testing terminal electroacoustical parameters, the bit rate giving the best characteristics or the most commonly used should be selected, e.g.:

- AMR-WB: 12,65 kbit/s [18];
- Recommendation ITU-T G.729.1: 32 kbit/s [5];

- EVS: 13,2 kbit/s [22].

5.2.1 Hand-held terminal

HATS measurement equipment shall be configured to the Hand-held hands-free UE according to figure 5.2. The HATS should be positioned so that the HATS Reference Point is at a distance d_{HF} from the centre point of the visual display of the Mobile Station. The distance d_{HF} is specified by the manufacturer. A vertical angle θ_{HF} may be specified by the manufacturer. In case it is not specified the distance d_{HF} shall be 42 cm and θ_{HF} shall be 0.

NOTE: The nominal distance of 42 cm corresponds to lip plane-HATS reference point distance (12 cm) with an additional 30 cm giving a realistic figure as a reference usage of handheld terminals.

Figure 5.2: Configuration of Hand-held Hands-free UE relative to the HATS

5.2.2 Vehicle mounted hands-free

Test arrangement, test methods and performance requirements are according to Recommendation ITU-T P.1110 [21].

Figure 5.3: Void

5.2.3 Desktop hands-free terminal

For HATS test equipment, definition of hands-free terminals and setup for desktop hands-free terminals is based on Recommendation ITU-T P.581 [14].

Figure 5.4: Position for test of desktop hands free terminal side view

Figure 5.5: Position for test of desktop hands free terminal top sight

5.2.4 Additional test setup for handsfree function with softphone

5.2.4.0 Introduction

Two types of softphones are to be considered:

- Type 1 is to be used as a desktop type (e.g. notebook).
- Type 2 is to be used as a handheld type (e.g. PDA).

When manufacturer gives conditions of use, they will apply for test. If no other requirement is given by manufacturer softphone will be positioned according the following conditions.

5.2.4.1 Softphone including speakers and microphone

Figure 5.6: Configuration of softphone relative to the HATS side view

Figure 5.7: Configuration of softphone relative to the HATS-top sight

5.2.4.2 Softphone with separate speakers

When separate loudspeakers are used, system will be positioned as in figure 5.8.

Figure 5.8: Configuration of softphone using external speakers relative to the HATS-top sight

When external microphone and speakers are used, system will be positioned as in figure 5.9.

Figure 5.9: Configuration of softphone using external speakers and microphone relative to the HATS-top sight

5.2.5 Test setup for variable echo path

Test setup for desktop hands free terminals: A notebook is positioned at least 20 cm in front of the device (or devices) with the transducers, as shown in figure 5.10. The notebook lid is moved during the measurement.

Figure 5.10: Positioning of DUT

Test setup for softphone: The test setup is described in clause 6.2. The notebook lid is moved during the measurement, as shown in figure 5.11. This setup is valid for all combinations of notebook with or without external speakers or microphone.

Figure 5.11: Positioning of DUT

Test setup for other handsfree devices is for further study.

5.3 Acoustical environment

In general different acoustical environments have to be taken into account: either room noise and background noise are an inherent part of the test environment or room noise and background noise shall be eliminated to such an extent that their influence on the test results can be neglected.

Unless stated otherwise measurements shall be conducted under quiet and "anechoic" conditions. Considering this, test laboratory, in the case where its test room does not conform to anechoic conditions as given in Recommendation ITU-T P.341 [11], has to present difference in results for measurements due to its test room. In case where an anechoic room is not available the test room has to be an acoustically treated room with few reflections and a low noise level.

In cases where real or simulated background noise is used as part of the testing environment, the original background noise shall not be noticeably influenced by the acoustical properties of the room.

In all cases where the performance of acoustic echo cancellers shall be tested, a realistic room, which represents the typical user environment for the terminal shall be used.

5.4 Test signals

Modern wireless terminals often deploy nonlinear and time-varying processing. As such terminals are designed for speech transmission, the most appropriate test signal is real speech. Appropriate test signals (general description) are defined in Recommendation ITU-T P.501 [12]. More information can be found in the test procedures described below.

For testing the wide-band telephony service provided by a terminal the test signal used shall be band limited between 100 Hz and 8 kHz with a bandpass filter providing a minimum of 24 dB/Oct. filter roll off, when feeding into the receive direction.

The test signal levels are referred to the average level of the (band limited in receive direction) test signal, averaged over the complete test sequence, unless specified otherwise.

Unless specified otherwise, the test signal levels are referred to the average level of the (band limited in receive direction) test signal, averaged over the complete test sequence, unless specified otherwise.

Unless specified otherwise, the test signal level shall be -4,7 dBPa at the MRP, calibrated at the various positions as defined in clause 5.5.1.

Unless specified otherwise, the applied test signal level at the digital input shall be -16 dBm0.

5.5 Calibration and test signal level

5.5.1 Send

Unless specified otherwise, the test signal level shall be -4,7 dBPa at the MRP.

The various steps for calibration of the artificial mouth are described in Recommendation ITU-T P.581 [14].

The test setup shall be in conformance with figure 5.10 but, depending on the type of terminal, the appropriate distance and level will be used. When using this calibration method, send sensitivity shall be calculated as follows:

$$S_{mj} = 20\log V_s - 20\log P_{MRP} + Corr - D_{corr} \quad (1)$$

Where:

V_s is the measured voltage across the appropriate termination (unless stated otherwise, a 600 ohm termination).

P_{MRP} is the applied sound pressure at the MRP.

Corr is $20 \log (P_{MRP}/P_{HFRP})$ of the used artificial mouth.

The value of Corr is the value required to calibrate the artificial mouth to the exact value of D_{corr} (e.g. 24,0 dB for 50 cm distance).

D_{corr} is the correction to achieve the target sound pressure level at the intended distance (see below).

NOTE: Reason for this procedure of calibration in two steps is to take into account the different variation of signal with distance by using different implementations of HATS.

Figure 5.12: Calibration at HFRP for HATS

The distance used for level calibration corresponds to the following values:

Desktop terminal: 50 cm and level to adjust - 28,7 dBPa, $D_{corr} = 24$ dB.

Handheld terminal: 30 cm with - 24,3 dBPa $D_{corr} = 20$ dB.

Softphone: 36 cm with - 25,8 dBPa Dcorr = 21 dB.

5.5.2 Receive

Unless specified otherwise, the applied test signal level at the digital input shall be -16 dBm0.

All measurement values produced by HATS are intended to be free-field equalized according Recommendation ITU-T P.581 [14].

5.5.3 Setup of background noise simulation

A setup for simulating realistic background noises in a lab-type environment is described in ETSI TS 103 224 [2].

ETSI TS 103 224 [2] contains a description of the recording arrangement for realistic background noises, a description of the setup for a loudspeaker arrangement suitable to simulate a background noise field in a lab-type environment and a database of realistic background noises, which can be used for testing the terminal performance with a variety of different background noises.

The principle loudspeaker setup for the simulation arrangement is shown in figure 5.13.

Figure 5.13: Loudspeaker arrangement for background noise simulation

The equalization and calibration procedure for the setup is described in detail in ETSI TS 103 224 [2].

If not stated otherwise this setup is used in all measurements where background noise simulation is required.

The following noises of ETSI TS 103 224 [2] shall be used.

Table 5.1: Noises used for background noise simulation

Name	Description	Length	Handset Levels
Full-size car 130 km/h (FullSizeCar_130)	HATS and microphone array at co-drivers position	30 s	1: 68,5 dB 2: 68,3 dB 3: 68,8 dB 4: 69,5 dB 5: 69,9 dB 6: 70,5 dB 7: 70,8 dB 8: 71,9 dB
Cafeteria (Cafeteria)	HATS and microphone array inside a cafeteria	30 s	1: 70,0 dB 2: 70,0 dB 3: 70,1 dB 4: 70,7 dB 5: 70,5 dB 6: 70,8 dB 7: 70,6 dB 8: 71,0 dB
Roadnoise (Roadnoise)	HATS and microphone array standing outside near a road	30 s	1: 72,8 dB 2: 71,6 dB 3: 72,0 dB 4: 72,9 dB 5: 72,2 dB 6: 73,1 dB 7: 73,0 dB 8: 73,8 dB
Pub Noise (Pub)	HATS and microphone array in a pub	30 s	1: 77,2 dB 2: 76,6 dB 3: 75,7 dB 4: 76,0 dB 5: 76,0 dB 6: 76,3 dB 7: 76,0 dB 8: 76,4 dB
Airport departure	HATS and microphone array in an airport gate area	30 s	1: 77,5 dB 2: 78,3 dB 3: 78,7 dB 4: 78,7 dB 5: 78,4 dB 6: 78,8 dB 7: 78,1 dB 8: 78,1 dB

5.6 Environmental conditions for tests

The following conditions shall apply for the testing environment:

- a) Ambient temperature: 15 °C to 35 °C (inclusive);
- b) Relative humidity: 5 % to 85 %;
- c) Air pressure: 86 kPa to 106 kPa (860 mbar to 1 060 mbar).

5.7 Accuracy of test equipment

Unless specified otherwise, the accuracy of measurements made by test equipment shall be better than:

Table 5.2: Accuracy of measurements

Item	Accuracy
Electrical Signal Level	±0,2 dB for levels ≥ -50 dBV
Electrical Signal Level	±0,4 dB for levels < -50 dBV
Sound pressure	±0,7 dB
Time	±0,2 %
Frequency	±0,2 %
Measured maximum frequency	20 kHz
Clock Accuracy	< 2 ppm

Unless specified otherwise, the accuracy of the signals generated by the test equipment shall be better than:

Table 5.3: Accuracy of generated signals

Quantity	Accuracy
Sound pressure level at MRP	±3 dB for 100 Hz to 200 Hz ±1 dB for 200 Hz to 4 kHz ±3 dB for 4 kHz to 14 kHz
Electrical excitation levels	±0,4 dB across the whole frequency range
Frequency generation	±2 % (see note)
Time	±0,2 %
NOTE: This tolerance may be used to avoid measurements at critical frequencies, e.g. those due to sampling and coding operations within the terminal under test.	

The measurements results shall be corrected for the measured deviations from the nominal level.

The sound level measurement equipment shall conform to IEC 61672 [19] Type 1.

5.8 Power feeding conditions

For terminal equipment which is directly powered from the mains supply, all tests shall be carried out within ±5 % of the rated voltage of that supply. If the equipment is powered by other means and those means are not supplied as part of the apparatus, all tests shall be carried out within the power supply limit declared by the supplier. If the power supply is a.c., the test shall be conducted within ±4 % of the rated frequency.

5.9 Influence of terminal delay on measurements

As delay is introduced by the terminal, care shall be taken for all measurements where exact position of the analysis window is required. It shall be checked that the test is performed on the test signal and not any other signal.

6 Codec independent requirements and associated Measurement Methodologies

6.1 Send and receive frequency response

6.1.1 Send frequency response

Requirement

The send sensitivity frequency response from the MRP to the measurement output (digital or analogue output according measurement system used) shall within the mask which can be drawn with straight lines between the breaking points in table 6.1 on a logarithmic (frequency) - linear (dB sensitivity) scale.

Table 6.1: Hands-free send sensitivity/frequency response

Frequency	Upper limit	Lower limit
100 Hz	4 dB	
125 Hz	4 dB	-10 dB
200 Hz	4 dB	-4 dB
1 000 Hz	4 dB	-4 dB
5 000 Hz	(see note)	-4 dB
6 300 Hz	9 dB	-7 dB
8 000 Hz	9 dB	
NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (Hz) scale.		

Figure 6.1: Hands-free send sensitivity/frequency response

Measurement method

The terminal will be positioned as described in clause 5.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12]. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The signal level is adjusted according to clause 5.5.

Measurements shall be made at one third-octave intervals as given by IEC 61260 [15] for frequencies from 100 Hz to 8 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBV/Pa.

6.1.2 Receive frequency response

6.1.2.1 Handheld terminal

Requirement

The receive sensitivity frequency response from the measurement input (digital or analogue input according measurement system used) to ear of HATS free field corrected shall be within the mask which can be drawn with straight lines between the breaking points in table 6.2 on a logarithmic (frequency) - linear (dB sensitivity) scale.

Table 6.2: Handheld terminal receive sensitivity/frequency response

Frequency	Upper limit	Lower limit
200 Hz	6 dB	
250 Hz	6 dB	
315 Hz	6 dB	
400 Hz	6 dB	-12 dB
500 Hz	6 dB	-6 dB
4 000 Hz	6 dB	-6 dB
5 000 Hz	6 dB	-9 dB
6 300 Hz	6 dB	-12 dB
7 000 Hz	6 dB	
8 000 Hz	6 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (Hz) scale.

**Figure 6.2: Handheld receive sensitivity/frequency response****Measurement method**

The terminal will be positioned as described in clause 5.2.

The measurement is conducted at nominal volume control setting.

Receive frequency response is the ratio of the measured sound pressure and the input level. (dB relative Pa/V).

$$S_{\text{Jeff}} = 20 \log (p_{e\text{ff}} / v_{\text{RCV}}) \text{ dB rel 1 Pa / V} \quad (2)$$

S_{Jeff} Receive Sensitivity; Junction to HATS ear with free field correction.

$p_{e\text{ff}}$ DRP Sound pressure measured by ear simulator Measurement data are converted from the Drum Reference Point to free field.

v_{RCV} Equivalent RMS input voltage.

The test signal used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12]. The test signal level shall be -16 dBm₀, measured according to Recommendation ITU-T P.56 [7] at the digital reference point or the equivalent analogue point.

The HATS is free field equalized as described in Recommendation ITU-T P.581 [14]. The equalized output signal is power-averaged on the total time of analysis. The 1/3 octave band data are considered as the input signal to be used for calculations or measurements.

Measurements shall be made at one third-octave intervals as given by IEC 61260 [15] for frequencies from 100 Hz to 8 kHz inclusive. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBPa/V.

6.1.2.2 Void

6.1.2.3 Softphone (computer-based terminals)

Type 1 or softphone with external speakers: The requirement as for desktop terminals applies.

Type 2: The requirement as for handheld terminals applies.

6.1.2.4 Desktop Terminal

Requirement

The receive sensitivity frequency response from the measurement input (digital or analogue input according measurement system used) to ear of HATS free field corrected shall be within the mask which can be drawn with straight lines between the breaking points in table 6.3 on a logarithmic (frequency) - linear (dB sensitivity) scale.

Requirement

Table 6.3: Desktop receive sensitivity/frequency response

Frequency	Upper limit	Lower limit
125 Hz	8 dB	
200 Hz	8 dB	-12 dB
250 Hz	8 dB	-9 dB
315 Hz	7 dB	-6 dB
400 Hz	6 dB	-6 dB
5 000 Hz	6 dB	-6 dB
6 300 Hz	6 dB	-9 dB
8 000 Hz	6 dB	

Figure 6.3: Desktop receive sensitivity/frequency response

Measurement method

The terminal is positioned as described in clause 5.2.

The measurement method described in clause 6.1.2.1 shall apply.

6.2 Send and receive loudness ratings

6.2.1 Send Loudness Ratings

Requirement

The nominal values of SLR shall be:

$$\text{SLR} = +13 \text{ dB} \pm 3 \text{ dB} \quad (3)$$

Measurement method

The terminal is positioned as described in clause 5.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12]. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The test signal level shall be -4,7 dBPa, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

Calibration is realized as explained in clause 5.2.1.

The send sensitivity shall be calculated from each band of the 20 frequencies given in table 1 of Recommendation ITU-T P.79 [9], bands 1 to 20. For the calculation the averaged measured level at the electrical reference point for each frequency band is referred to the averaged test signal level measured in each frequency band at the MRP.

The sensitivity is expressed in terms of dBV/Pa and the SLR shall be calculated according to Recommendation ITU-T P.79 [9], annex A.

6.2.2 Microphone (Mic) mute

Requirement

The SLR (Send Loudness Rating) with mic mute on shall be at least 50 dB higher than with mic mute off.

Measurement method

The terminal will be positioned as described in clause 5.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12]. The spectrum of acoustic signal produced by the artificial mouth is calibrated under free field conditions at the MRP. The test signal level shall be -4,7 dBPa, measured at the MRP. The test signal level is averaged over the complete test signal sequence.

Calibration is realized as explained in clause 5.2.1.

The send sensitivity shall be calculated from each band of the 20 frequencies given in table 1 of Recommendation ITU-T P.79 [9], bands 1 to 20. For the calculation the averaged measured level at the electrical reference point for each frequency band is referred to the averaged test signal level measured in each frequency band at the MRP.

The sensitivity is expressed in terms of dBV/Pa and the SLR shall be calculated according to Recommendation ITU-T P.79 [9], annex A.

6.2.3 Receive Loudness Ratings

Requirement

Handheld terminal

Nominal value of RLR will be $9 \text{ dB} \pm 3 \text{ dB}$. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range shall be less than (louder) or equal to 5 dB: $\text{RLR} \leq 5 \text{ dB}$.

Range of volume control shall be equal or exceed 15 dB.

Softphone (computer-based terminal)

Type 1 or softphone with external speakers: requirement as for desktop terminal.

Type 2 requirement as for handheld terminal.

Desktop terminal

Nominal value of RLR will be $5 \text{ dB} \pm 3 \text{ dB}$. This value has to be fulfilled for one position of volume range.

The value of RLR at the upper part of the volume range shall be less than (louder) or equal to -2 dB: $\text{RLR} \leq -2 \text{ dB}$.

The range of volume control shall be equal or exceed 15 dB.

Group audio terminal

Nominal value of RLR will be $5 \text{ dB} \pm 3 \text{ dB}$. This value has to be fulfilled for one position of volume range.

Value of RLR at upper part of volume range shall be less than (louder) or equal to -6 dB: $\text{RLR} \leq -6 \text{ dB}$.

Range of volume control shall be equal or exceed 19 dB.

NOTE: Due to the lack of experience in the application of wide band loudness rating calculation as defined in annex G of Recommendation ITU-T P.79 [9] the loudness rating calculation as described in annex A is used.

Measurement method

The terminal will be positioned as described in clause 5.2.

The test signal to be used for the measurements shall be the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12]. The test signal level shall be -16 dBm₀, measured according to Recommendation ITU-T P.56 [7] at the digital reference point or the equivalent analogue point.

The receive sensitivity shall be calculated from each band of the 20 frequencies given in table 1 of Recommendation ITU-T P.79 [9], bands 1 to 20. For the calculation the averaged measured level at each frequency band is referred to the averaged test signal level measured in each frequency band.

The sensitivity is expressed in terms of dBPa/V and the RLR shall be calculated according to Recommendation ITU-T P.79 [9], annex A. The RLR shall then be computed as $\text{RLR}(\text{cal}) - 14 \text{ dB}$ according to Recommendation ITU-T P.340 [10]), and without the LE factor.

The test shall be repeated for maximum volume control setting.

6.3 Send and receive noise

6.3.1 Send Noise

Requirement

The send noise shall not exceed -64 dBm0(A).

No peaks in the frequency domain higher than 10 dB above the average noise spectrum shall occur.

Requirement as for other tests is identical for all types of terminals.

NOTE: Softphones with cooling devices (fans) can produce a rather high level of noise, furthermore largely dependent of activity of system.

Measurement method

The terminal will be positioned as described in clause 5.2.

For the actual measurement no test signal is used. In order to reliably activate the terminal an activation signal is introduced before the actual measurement. The activation signal shall be the female speaker signal of the short conditioning sequence described in clause 7.3.7 of in Recommendation ITU-T P.501 [12]. The level of this activation signal shall be -4,7 dBPa, measured at the MRP. The activation signal level is averaged over the complete activation signal sequence.

The send noise is measured at the POI in the frequency range from 100 Hz to 8 kHz. The analysis window is applied directly after stopping the activation signal but taking into account the influence of all acoustical components (reverberations). The averaging time is 1 second. The test house has to ensure (e.g. by monitoring the time signal) that during the test the terminal remains in activated condition. If the terminal is deactivated during the measurement, the measurement time has to be reduced to the period where the terminal remains in activated condition.

The noise level is measured in dBm0(A).

Spectral peaks are measured in the frequency domain from 100 Hz to 6,3 kHz. The frequency spectrum of the A-weighted idle channel noise is measured by a spectral analysis having a noise bandwidth of 8,79Hz (determined using FFT 8 k samples/48 kHz sampling rate with Hanning window or equivalent). The idle channel noise spectrum is stated in dB. A smoothed average idle channel noise spectrum is calculated by a moving average (arithmetic mean) 1/3rd octave wide across the idle noise channel spectrum stated in dB (linear average in dB of all FFT bins in the range from $2^{-1/6}f$ to $2^{+1/6}f$). Peaks in the idle channel noise spectrum are compared against a smoothed average idle channel noise spectrum.

6.3.2 Receive Noise

Requirement

A-weighted

The receive noise level shall not exceed -54 dBPa(A) at **nominal setting of the volume control**.

Third-octave band spectrum

The level in any 1/3-octave band, between 100 Hz and 10 kHz shall not exceed a value of -64 dBPa.

NOTE 1: No peaks in the frequency domain higher than 10 dB above the average noise spectrum can occur.

NOTE 2: For softphone the test condition excludes fan noise.

Measurement method

The terminal will be positioned as described in clause 5.2.

For the actual measurement no test signal is used. In order to reliably activate the terminal an activation signal is introduced before the actual measurement. The activation signal shall be the female speaker signal of the short conditioning sequence described in clause 7.3.7 of in Recommendation ITU-T P.501 [12]. The level of this activation signal shall be -16 dBm0.

The A-weighted noise level shall be measured at DRP of the artificial ear with the diffusefield equalization active. The noise level is measured until 10 kHz.

The level in any 1/3-octave band, between 100 Hz and 10 kHz shall be measured at DRP of the artificial ear with the diffusefield equalization active.

The noise shall be measured just after interrupting the activation signal.

Spectral peaks are measured in the frequency domain in the frequency range from 100 Hz to 6,3 kHz. The frequency spectrum of the A-weighted idle channel noise is measured by a spectral analysis having a noise bandwidth of 8,79 Hz (determined using FFT 8 k samples/48 kHz sampling rate with Hanning window or equivalent). The idle channel noise spectrum is stated in dB. A smoothed average idle channel noise spectrum is calculated by a moving average (arithmetic mean) 1/3rd octave wide across the idle noise channel spectrum stated in dB (linear average in dB of all FFT bins in the range from $2^{(-1/6)f}$ to $2^{(+1/6)f}$). Peaks in the idle channel noise spectrum are compared against a smoothed average idle channel noise spectrum.

NOTE 3: Care should be taken that only the noise is windowed out by the analysis and the analysis window is not impaired by any remaining reverberance or room noise.

6.4 Send and receive distortion

6.4.0 General

It is not intended to provide coder-dependant requirements but to assess the electroacoustic performances of the terminal.

6.4.1 Send distortion

Requirement

The ratio of signal to harmonic distortion shall be above the following mask.

Table 6.4: Limits for harmonic distortion ratio for send

Frequency (Hz)	Signal to harmonic distortion ratio limit, send (dB)
200	25
315	26
400	30
1 000	30
2 000	30
NOTE: The limits for intermediate frequencies lie on straight lines drawn between the given values on a linear (dB) - logarithmic (Hz) scale.	

Measurement method

The terminal will be positioned as described in clause 5.2.

After the correct activation of the system, a sinewave signal at frequencies of 200 Hz, 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz, 1 000 Hz and 2 kHz is applied. The duration of the sine-wave shall be of less than 1 s. The sinusoidal signal level shall be calibrated to -4,7 dBPa at the MRP.

The signal to harmonic distortion ratio is measured selectively up to 7 kHz.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] shall be used for activation. The level of this activation signal shall be -4,7 dBPa at the MRP.

NOTE: Depending on the type of codec the test signal used may need to be adapted.

6.4.2 Receive distortion

Requirement

- **Handheld terminal**

The ratio of signal to harmonic distortion shall be above the following mask.

Table 6.5: Limits for harmonic distortion ratio for receive

Frequency	Signal to distortion ratio limit, receive for vehicle mounted or desktop terminal at nominal volume	Signal to distortion ratio limit, receive for handheld terminal at nominal volume	Signal to distortion ratio limit, receive for all terminals at maximum volume
315 Hz	26 dB		
400 Hz	30 dB		
500 Hz	30 dB	20 dB	
800 Hz	30 dB	30 dB	20 dB
1 kHz	30 dB	30 dB	
2 kHz	30 dB	30 dB	
3 kHz	30 dB	30 dB	

NOTE: The limits for intermediate frequencies lie on a straight line drawn between the given values on a linear (dB) - logarithmic (kHz) scale.

- **Softphone (computer-based terminal)**

For a type 1 or softphone with external speakers the requirements given in table 6.5 (desktop terminal) shall apply.

For a Type 2 terminal the requirements given in table 6.5 (as for handheld terminals) shall apply.

- **Desktop terminal**

The ratio of signal to harmonic distortion is given in table 6.5.

Measurement method

Test setup is described in clause 5.2.

After a correct activation of the system, a sinewave signal at frequencies of 315 Hz, 400 Hz, 500 Hz, 630 Hz, 800 Hz, 1 000 Hz, 2 000 Hz, 3 000 Hz is applied at the digital interface. The duration of the sine-wave shall be of less than 1 s. The sinusoidal signal level shall be -16 dBm0.

The female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] shall be used for activation. The level of this activation signal shall be -16 dBm0.

The signal to harmonic distortion ratio is measured selectively up to 10 kHz.

NOTE: Depending on the type of codec the test signal used may need to be adapted.

6.5 Terminal Coupling Loss

Requirement

In order to meet talker echo objective requirements [6], the recommended terminal coupling loss during single talk (TCLst) should be greater than 55 dB when measured under free field conditions at **nominal setting of the volume control**.

The TCL measured as unweighted Echo Loss shall be ≥ 46 dB for all settings of the volume control (if supplied).

NOTE 1: A TCL ≥ 50 dB is recommended as a performance objective. Depending on the idle channel noise in the sending direction, it may not always be possible to measure an echo loss ≥ 50 dB.

Measurement method

The setup for terminal is described in clause 5.2.

For hands-free measurement, HATS is positioned but not used.

For loudspeaking measurement, handset is positioned on HATS (right ear).

The attenuation from electrical reference point input to electrical reference point output shall be measured using the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [12]. The signal level shall be -10 dBm0.

The TCL is calculated as the difference between the averaged test signal level and the averaged echo level in the frequency range from 100 Hz to 8 000 Hz. For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band. The first 17,0 seconds of the test signal (6 sentences) are discarded from the analysis to allow for convergence of the acoustic echo canceller. The analysis is performed over the remaining length of the test sequence (last 6 sentences). For the measurement, a time window has to be applied which is adapted to the duration of the actual test signal. The echo loss is calculated by the equations:

$$L_e = C - 10 \log_{10} \sum_{i=1}^N (A_i + A_{i-1}) (\log_{10} f_i - \log_{10} f_{i-1}) \quad (4)$$

and

$$C = 10 \log_{10} (2 (\log_{10} f_N - \log_{10} f_0)) \quad (5)$$

where:

- A_0 is the output/input power ratio at frequency $f_0 = 100$ Hz;
- A_1 the ratio at frequency f_i ; and
- A_N the ratio at frequency $f_N = 8\ 000$ Hz.

Equation (5) is a generalized form of the equation defined in clause B.4 of Recommendation ITU-T G.122 [3] for calculating echo loss based on tabulated data, which allows the calculation of echo loss within any frequency range between f_0 and f_N .

The ambient noise level shall be < -64 dBPa(A).

NOTE 2: The extension of the frequency range is for further study.

NOTE 3: Care should be taken when measuring TCL: the echo return not to be masked by the residual noise or the comfort noise when implemented.

6.6 Stability Loss (or similar parameters)

Requirement

For the calculation the averaged measured echo level at each frequency band is referred to the averaged test signal level measured in each frequency band. It shall exceed 6 dB for all frequencies and for all settings of volume control.

Measurement method

Test set-up is identical as for TCL_W .

Before the actual test a training sequence consisting of the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12] shall be applied. The training sequence level shall be -16 dBm0 in order not to overload the codec.

The test signal is a PN sequence complying with Recommendation ITU-T P.501 [12] with a length of 4 096 points (for the 48 kHz sampling rate) and a crest factor of 6 dB. The duration of the test signal is 250 ms. With an input signal of -3 dBm0, the attenuation from digital input to digital output shall be measured for frequencies from 100 Hz to 8 kHz.

6.7 Double talk performance

6.7.0 Introduction

During double talk the speech is mainly determined by 2 parameters: impairment caused by echo during double talk and level variation between single and double talk (attenuation range).

In order to guarantee sufficient quality under double talk conditions the Talker Echo Loudness Rating should be high and the attenuation inserted should be as low as possible. Terminals which do not allow double talk in any case should provide a good echo attenuation which is realized by a high attenuation range in this case.

The most important parameters determining the speech quality during double talk are (see Recommendations ITU-T P.340 [10] and P.502 [13]):

- Attenuation range in send direction during double talk $A_{H,S,dt}$.
- Attenuation range in receive direction during double talk $A_{H,R,dt}$.
- Echo attenuation during double talk.

The categorization of a terminal is based on the three categories defined in clauses 6.7.1, 6.7.2 and 6.7.3 and this categorization is given by the "lowest" of the three parameters e.g. if $A_{H,S,dt}$ provides 2a, $A_{H,R,dt}$ 2b and echo loss 1, the categorization of the terminal is 2b.

6.7.1 Attenuation Range in Send Direction during Double Talk

Requirement

Based on the level variation in send direction during double talk $A_{H,S,dt}$ the behaviour of the terminal can be classified according to table 6.6.

Table 6.6

Category (according to Recommendation ITU-T P.340 [10])	1	2a	2b	2c	3
	Full Duplex Capability	Partial Duplex Capability			No Duplex Capability
$A_{H,S,dt}$ [dB]	≤ 3	≤ 6	≤ 9	≤ 12	> 12

In general this table provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.

The category of the terminal according to table 6.6 shall be noted in the test report.

Test Signal

The test signal to determine the attenuation range during double talk is the double talk speech sequence as defined in clause 7.3.5 of Recommendation ITU-T P.501 [12] as shown in figure 6.4. The competing speaker is always inserted as the double talk sequence $s_{dt}(t)$ either in send or receive and is used for analysis.

Figure 6.4: Double Talk Test Sequence with overlapping speech sequences in send and receive direction

Measurement method

The long conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] shall be used for conditioning the terminal, with the female speaker in the receive direction. The attenuation range during double talk is determined as described in Appendix III of Recommendation ITU-T P.502 [13]. The double talk performance is analysed for each word and sentence produced by the competing speaker. The requirement has to be met for each word and sentence produced by the competing speaker.

The settings for the test signals are as follows.

Table 6.7

	Receive direction	Send direction
Average signal level for speakerphone HFT	-16 dBm0	-1,7 dBPa
Average signal level for desktop HFT	-16 dBm0	-1,7 dBPa

The terminal is positioned as described in clause 5.2. Before the actual test, a training sequence for the echo canceller consisting of the British-English single talk sequence described in clause 7.3.2 of Recommendation ITU-T P.501 [12] with a level of -16 dBm0 is applied to the electrical reference point.

When determining the attenuation range in send direction, the signal measured at the electrical reference point is referred to the test signal inserted.

The attenuation range during double talk is determined as described in Appendix III of Recommendation ITU-T P.502 [13]. The double talk performance is analysed for the sequence of words and the sequence of sentences produced by the competing speaker. The requirement has to be met for the sequence of words and the sequence of sentences produced by the competing speaker. The measurement shall be done also for desktop terminals and softphones with variable echo path.

6.7.2 Attenuation Range in Receive Direction during Double Talk

Requirement

Based on the level variation in receive direction during double talk $A_{H,R,dt}$ the behaviour of the terminal can be classified according to table 6.8.

Table 6.8

Category (according to Recommendation ITU-T P.340 [10])	1	2a	2b	2c	3
	<i>Full Duplex Capability</i>	<i>Partial Duplex Capability</i>			<i>No Duplex Capability</i>
$A_{H,R,dt}$ [dB]	≤ 3	≤ 5	≤ 8	≤ 10	> 10

In general this table provides a quality classification of terminals regarding double talk performance. However, this does not mean that a terminal which is category 1 based on the double talk performance is of high quality concerning the overall quality as well.

The category of the terminal according to table 6.8 shall be noted in the test report.

Measurement method

The test setup is described in clause 5.2.

The long conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] shall be used for conditioning the terminal, with the female speaker in the receive direction. The test signal to determine the attenuation range during double talk is shown in figure 6.4. A sequence of speech signals is used which is inserted in parallel in send and receive direction. The test signals are synchronized in time at the acoustical interface. The delay of the test arrangement shall be constant during the measurement.

The settings for the test signals are as follows.

Table 6.9

	Receive direction	Send direction
Average signal level for speakerphone HFT	-16 dBm0	-1,7 dBPa
Average signal level for desktop HFT	-16 dBm0	-1,7 dBPa

When determining the attenuation range in receive direction, the signal measured at the loudspeaker of the hands-free terminal is referred to the test signal inserted.

The attenuation range during double talk is determined as described in Appendix III of Recommendation ITU-T P.502 [13]. The double talk performance is analysed for the sequence of words and the sequence of sentences produced by the competing speaker. The requirement has to be met for the sequence of words and the sequence of sentences produced by the competing speaker.

The measurement shall be done also for desktop terminals and softphones with variable echo path.

6.7.3 Detection of echo components during double Talk

Requirement

"Echo Loss" (EL) is the echo suppression provided by the terminal measured at the electrical reference point. Under these conditions the requirements given in table 6.10 are applicable (more information can be found in annex A of the Recommendation ITU-T P.340 [10]).

Table 6.10

Category (according to Recommendation ITU-T P.340 [10])	1	2a	2b	2c	3
	<i>Full Duplex Capability</i>	<i>Partial Duplex Capability</i>			<i>No Duplex Capability</i>
Echo Loss [dB]	≥ 27	≥ 23	≥ 17	≥ 11	< 11

NOTE: The echo attenuation during double talk is based on the parameter Talker Echo Loudness Rating ($TELR_{dt}$). It is assumed that the terminal at the opposite end of the connection provides nominal Loudness Rating ($SLR + RLR = 10$ dB).

The category of the terminal according to table 6.10 shall be noted in the test report.

Measurement method

The test setup is described in clause 5.2.

The double talk signal consists of a sequence of orthogonal signals which are realized by voice-like modulated sine waves spectrally shaped similar to speech. A detailed description can be found in Recommendation ITU-T P.501 [12]. The signal settings used are given in table 6.11.

The settings for the signals are as follows.

Table 6.11: Parameters of the two Test Signals for Double Talk Measurement based on AM-FM modulated sine waves

Send direction		Receive direction	
$f_0^{(1)}$ (Hz)	$\pm \Delta f^{(1)}$ (Hz)	$f_0^{(2)}$ (Hz)	$\pm \Delta f^{(2)}$ (Hz)
125	$\pm 2,5$	180	$\pm 2,5$
250	± 5	270	± 5

The signal generation is according to Recommendation ITU-T P.501 [12].

The signals are fed simultaneously in send and receive direction. The level in send direction is -4,7 dBPa at the MRP (nominal level), the level in receive direction is -16 dBm0 at the electrical reference point (nominal level).

The test signal is measured at the electrical reference point (send direction). The measured signal consists of the double talk signal which was fed in by the artificial mouth and the echo signal. The echo signal is filtered by comb filter using mid-frequencies and bandwidth according to the signal components of the signal in receive direction (see Recommendation ITU-T P.501 [12]). The filter will suppress frequency components of the double talk signal.

In each frequency band which is used in receive direction the echo attenuation can be measured separately. The requirement for category 1 is fulfilled if in any frequency band the echo signal is either below the signal noise or below the required limit. If echo components are detectable, the classification is based on table 6.11. The echo attenuation is to be achieved for **each individual frequency band** according to the different categories.

The measurement shall be done also for desktop terminals and softphones with variable echo path.

6.7.4 Minimum activation level and sensitivity of double talk detection

For further study.

6.8 Switching parameters

6.8.0 Clarification

Additional requirements may be needed in order to further investigate the effect of NLP implementations on the users' perception of speech quality.

6.8.1 Activation in Send Direction

The activation in send direction is mainly determined by the built-up time $T_{r,S,min}$ and the minimum activation level ($L_{S,min}$). The minimum activation level is the level required to remove the inserted attenuation in send direction during idle mode. The built-up time is determined for the test signal burst which is applied with the minimum activation level.

The activation level described in the following is always referred to the test signal level at the Mouth Reference Point (MRP).

Requirement

The minimum activation level $L_{s,min}$ shall be ≤ -20 dBPa.

The built-up time $T_{r,S,min}$ (measured with minimum activation level) shall be ≤ 15 ms.

Measurement method

The test setup is described in clause 5.2.

The test signal is the "short words for activation" sequence described in clause 7.3.4 of Recommendation ITU-T P.501 [12].

The settings of the test signal are as follows.

Table 6.12: Settings for the signal

	CSS Duration/ Pause Duration	Level of the first CS Signal (active Signal Part at the MRP)	Level Difference between two Periods of the Test Signal
Single word to Determine Switching Characteristic in Send Direction	~600 ms / ~400 ms	-24 dBPa (see note 1)	1 dB
NOTE 1: The level of the active signal part corresponds to an average level of -24,7 dBPa at the MRP for the CSS according to Recommendation ITU-T P.501 [12].			
NOTE 2: The signal level is determined for each utterance individually according to Recommendation ITU-T P.56 [7].			

It is assumed that the pause length of about 400 ms is longer than the hang-over time so that the test object is back to idle mode after each single word.

The level of the transmitted signal is measured at the electrical reference point. The test signal is filtered by the transfer function of the test object. The measured signal level is referred to the filtered test signal level and displayed vs. time. The levels are calculated from the time domain using an integration time of 5 ms.

The minimum activation level is determined from the single word which indicates the first activation of the test object. The time between the beginning of the single word and the complete activation of the test object is measured.

6.8.2 Minimum activation level and sensitivity in Receive direction

For further study.

6.8.3 Automatic level control

For further study.

6.8.4 Silence Suppression and Comfort Noise Generation

For further study.

6.9 Background noise performance

6.9.1 Performance in send direction in the presence of background noise

Requirement

The level of comfort noise, if implemented, shall be within in a range of +2 dB and -5 dB compared to the original (transmitted) background noise. The noise level is calculated with A weighting.

NOTE 1: It is advisable that the comfort noise matches the original signal as good as possible (from a perception point of view).

NOTE 2: Input for further specification necessary (e.g. on temporal matching).

The spectral difference between comfort noise and original (transmitted) background noise shall be within the mask given through straight lines between the breaking points on a logarithmic (frequency) - linear (dB sensitivity) scale as given in table 6.13.

Table 6.13: Requirements for Spectral Adjustment of Comfort Noise (Mask)

Frequency	Upper Limit	Lower Limit
200 Hz	12 dB	-12 dB
800 Hz	12 dB	-12 dB
800 Hz	10 dB	-10 dB
2 000 Hz	10 dB	-10 dB
2 000 Hz	6 dB	-6 dB
4 000 Hz	6 dB	-6 dB
8 000 Hz	6 dB	-6 dB

NOTE: All sensitivity values are expressed in dB on an arbitrary scale.

Measurement method

The test setup is described in clause 5.2.

The background noise simulation as described in clause 5.5.3 is used.

First the background noise transmitted in send is recorded at the POI for a period of at least 20 s.

In a second step a test signal is applied in receive direction consisting of an initial pause of 10 s and a periodical repetition of the Composite Source Signal in receive direction (duration 10 s) with nominal level to enable comfort noise injection simultaneously with the background noise. For the measurement the background noise sequence has to be started at the same point as it was started in the previous measurement. Alternatively other speech like test signals (e.g. artificial voice) with the same signal level can be used.

The transmitted signal is recorded in send direction at the POI.

The power density spectra measured in send direction without far end speech simulation averaged between 10 s and 20 s is referred to the power density spectrum measured in send direction determined during the period with far end speech simulation in receive direction averaged between 10 s and 20 s. Level and spectral differences between both power density spectra are analysed and compared to the requirements.

6.9.2 Speech Quality in the Presence of Background Noise**Requirement**

Speech Quality for wideband systems shall be tested based on ETSI TS 103 106 [20].

For the background noises defined in clause 5.5.3 the following requirements apply:

- N-MOS-LQO_w ≥ 3,0.
- S-MOS-LQO_w ≥ 3,0.
- G-MOS-LQO_w ≥ 3,0.

NOTE: It is recommended to test the terminal performance with other types of background noises if the terminal is likely to be exposed to other noises than specified in clause 5.5.3.

Measurement method

The background noise simulation as described in clause 5.5.3 is used. The handset terminal is set-up as described in clause 5.2.

The background noise shall be applied for at least 5 s in order to adapt noise reduction algorithms in advance the test.

The near end speech signal consists of 16 sentences of speech (2 male and 2 female talkers, 4 sentences each). An appropriate measurement sequence in American English is provided in annex C of ETSI TS 103 106 [20]. The test signal level is +1,3 dBPa at the MRP.

Three signals are required for the tests:

- 1) The clean speech signal is used as the undisturbed reference.

- 2) The speech plus undisturbed background noise signal is recorded at the terminal's microphone position using an omni directional measurement microphone with a linear frequency response between 50 Hz and 12 kHz.
- 3) The send signal is recorded at the electrical reference point.

N-MOS-LQOw, S-MOS LQOw and G-MOS LQOw are calculated as described in ETSI TS 103 106 [20].

6.9.3 Quality of Background Noise Transmission (with Far End Speech)

Requirement

The test is carried out applying a speech signal in receive direction. The test is carried out by comparing the noise level transmitted in the sending direction under reference conditions with no far end speech, to the noise level transmitted in the sending direction under test conditions including far end speech. During and after the end of the speech signal the signal level in send direction shall not vary more than 10 dB (during transition to transmission of background noise without far end speech). The measurement is conducted for all types of background noise as defined in clause 5.5.

NOTE: The intention of this measurement is to detect impairments (modulations, switching and others) influencing the background noise transmitted from the terminal under test when a signal from the distant end (receiving side of the terminal under test) is present. Under these test conditions no modulation of the transmitted signal should occur. Modulation, switching or other type of impairments might be caused by an improper behaviour of a nonlinear processor working in conjunction with the echo canceller and erroneously switching or modulating the transmitted background noise.

Measurement method

The test setup is described in clause 5.2.

The background noises are generated as described in clause 5.5.3.

First the measurement is conducted without inserting the signal at the far end. At least 10 s of noise are analysed. The background signal level versus time is calculated using a time constant of 35 ms. This is the reference signal.

In a second step the same measurement is conducted, but with inserting the speech signal at the far end. The exactly identical background noise signal is applied. The background noise signal should start at the same point in time as was used for the reference measurement without the far end signal. The background noise shall be applied for at least 5 s in order to allow adaptation of the noise reduction algorithms. After at least 5 s a series of the female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] is applied in receive direction with duration of at least 10 s. The test signal level in the receiving direction is -16 dBm0 at the electrical reference point.

For both, reference and test conditions the send signal is recorded at the electrical reference point and the test signal level versus time is calculated using a time constant of 35 ms.

The level variation in send direction is determined during the time interval when the speech signal is applied and after it stops. The level difference is determined from the difference of the recorded signal levels versus time between reference signal and the signal measured with far end signal.

6.10 Quality of echo cancellation

6.10.1 Temporal echo effects

Requirement

This test is intended to verify that the system will maintain sufficient echo attenuation during single talk. The measured echo attenuation during single talk shall not decrease by more than 6 dB from the maximum measured during the TCLw test.

Measurement method

The test arrangement is according to clause 5.2.

The background noises are generated as described in clause 5.5.

First, the reference measurement is conducted without inserting the signal at the far end. At least 10 seconds of noise is analysed. The background level versus time is calculated using a time constant of 35 ms. This is the reference signal.

In a second step the same measurement is conducted, but with inserting the speech signal at the far end. The exactly identical background noise signal is applied. The background noise signal should start at the same point in time as was used for the reference measurement without the far end signal. The background noise should be applied for at least 5 s in order to allow adaptation of the noise reduction algorithms. After at least 5 s a series of the female speaker signal of the short conditioning sequence described in clause 7.3.7 of Recommendation ITU-T P.501 [12] is applied in receive direction with duration of at least 10 s. The test signal level in the receiving direction is -16 dBm0 at the electrical reference point.

For both reference and test conditions, the send signal is recorded at the electrical reference point and the level versus time is calculated using a time constant of 35 ms.

The level variation in send direction is determined during the time interval when the speech signal is applied and after it stops. The level difference is determined from the difference of the recorded signal levels versus time between reference signal and the signal measured with far end signal.

NOTE: Care should be taken not to confuse noise or comfort noise with residual echo. In cases of doubt the measured echo signal should be compared to the residual noise signal measured under the same conditions without inserting the receive signal. If the level vs. time analysis leads to the identical result it can be assumed that no echo but just comfort noise is present.

6.10.2 Spectral Echo Attenuation

Requirement

The echo attenuation vs. frequency shall be below the tolerance mask given in table 6.14.

Table 6.14: Spectral echo loss limits

Frequency	Limit
100 Hz	-41 dB
1 300 Hz	-41 dB
3 450 Hz	-46 dB
5 200 Hz	-46 dB
7 500 Hz	-37 dB
8 000 Hz	-37 dB

NOTE: The limit at intermediate frequencies lies on a straight line drawn between the given values on a log (frequency) - linear (dB) scale.

During the measurement it should be ensured that the measured signal is really the echo signal and not the Comfort Noise which possibly may be inserted in send direction in order to mask the echo signal.

Measurement method

The test setup is described in clause 5.2.

Before the actual measurement a training sequence is fed in consisting of the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [12]. The level of the training sequence shall be -16 dBm0.

The test signal is the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [12]. The average test signal level shall be -16 dBm0, averaged over the complete test signal. The power density spectrum of the measured echo signal is referred to the power density spectrum of the original test signal. The analysis is conducted using FFT analysis with 8 k points (48 kHz sampling rate, Hanning window).

The spectral echo attenuation is analysed in the frequency domain in dB.

6.10.3 Occurrence of Artefacts

For further study.

6.10.4 Variable echo path

Requirement

This test is intended to verify that the system will maintain sufficient echo attenuation during single talk with dynamic changing echo paths. The measured echo level over time during single talk shall not be more than 10 dB above the minimum noise level during the measurement.

Measurement method

The test setup is described in clause 5.2.5.

NOTE: Care should be taken to not generate noise during the movement of the notebook lid. Because of this, this measurement is not applicable for a softphone without external microphone.

As test signal the compressed real speech signal described in clause 7.3.3 of Recommendation ITU-T P.501 [12] is used. The signal level shall be -10 dBm0. The terminal volume control is set to nominal RLR. The first 4 sentences of the test signal are used to allow full convergence of the echo canceller. The next 4 sentences (from 10,75 s to 22,5 s) are used for the analysis. The echo signal level is analysed over time. The echo signal level is analysed for 11,75 s, using a time constant of 35 ms.

The measurement result is displayed as echo level versus time.

No level peak shall be more than 10 dB above the minimum noise level during the measurement.

6.11 Send and receive delay or round trip delay

Requirement

Send and receive delays are tested separately but the requirement is defined for the combination of send and receive delays (round-trip delay).

It is recognized that the end to end delay should be as small as possible in order to ensure high quality of the communication.

The round-trip delay T_{rtd} (sum of send and receive delay) shall be less than 100 ms (category B in Recommendation ITU-T P-1010 [23]).

From the users perspective, a value less than 50 ms (category A in Recommendation ITU-T P-1010 [23]) is preferred.

Measurement method

- Send direction

The delay in send direction is measured from the MRP (Mouth Reference Point) to POI (reference speech codec of the system simulator, output). The delay measured in send direction is:

$$T_s + t_{\text{system}} \quad (6)$$

NOTE 1: The delay should be minimized! This can, e.g. be accomplished by designing the speech decoder output, the additional radio link, and the hands-free system in a way, that sample-based processing and frame-based processing interoperate by using common buffers at their interfaces.

Figure 6.5: Different blocks contributing to the delay in send direction

The system delay t_{system} is depending on the transmission method used and the network simulator. The delay t_{system} should be known.

- 1) For the measurements a Composite Source Signal (CSS) according to Recommendation ITU-T P.501 [12] is used. The pseudo random noise (pn)-part of the CSS has to be longer than the maximum expected delay. It is recommended to use a pn sequence of 16 k samples (with 48 kHz sampling rate). The test signal level is -4,7 dBPa at the MRP. The test signal level is adjusted to -28,7 dBPa at the HATS-HFRP (see Recommendation ITU-T P.581 [14]). The equalization of the artificial mouth is made at the MRP.

The reference signal is the original signal (test signal).

The setup of the hands-free terminal is in correspondence to clause 5.2.

- 2) The delay is determined by cross-correlation analysis between the measured signal at the electrical access point and the original signal. The measurement is corrected by delays which are caused by the test equipment.
 - 3) The delay is measured in ms and the maximum of the envelope of the cross-correlation function is used for the determination.
- Receive direction

The delay in receive direction is measured from POI (input of the reference speech coder of the system simulators) to the Drum Reference Point (DRP). The delay measured in receive direction is:

$$T_r + t_{\text{System}} \quad (7)$$

NOTE 2: The delay should be minimized! This can, e.g. be accomplished by designing the speech decoder output, the additional radio link, and the hands-free system in a way, that sample-based processing and frame-based processing interoperate by using common buffers at their interfaces. Careful matching of frame shift and DFT size for the signal processing in the hands-free system to the additional radio link and to the speech coder allows to (partially) embed the delay of one block into the preceding one.

Figure 6.6: Different blocks contributing to the delay in receive direction

The system delay t_{System} is depending on the transmission system and on the network simulator used. The delay t_{System} should be known.

- 1) For the measurements a Composite Source Signal (CSS) according to Recommendation ITU-T P.501 [12] is used. The pseudo random noise (pn)-part of the CSS has to be longer than the maximum expected delay. It is recommended to use a pn sequence of 16 k samples (with 48 kHz sampling rate). The test signal level is -16 dBm0 at the electrical interface (POI).

The reference signal is the original signal (test signal).

- 2) The test arrangement is according to clause 5.2. Artificial head is free-field according to Recommendation ITU-T P.581 [14]. The equalized output signal of the right ear is used for the measurement.
- 3) The delay is determined by cross-correlation analysis between the measured signal at the DRP and the original signal. The measurement is corrected by delays which are caused by the test equipment.
- 4) The delay is measured in ms and the maximum of the envelope of the cross-correlation function is used for the determination.

6.12 Objective listening Quality in send and receive direction

The aim is to provide the best listening quality whatever the implementation is.

Provisional target value: $\text{MOS-LQO}_M > 4,0$.

As the actual listening quality depends on the codec implementation, specific requirements and test methods are defined in clause 7.

This clause will be updated when the relevant quality model will be available.

7 Codec dependent requirements and associated Measurement Methodologies

7.1 Speech Coders

The present document is intended to be applicable for different speech coders implemented in access networks and additional links.

Table 7.1 defines a list of speech coders implemented (non exhaustive).

Table 7.1: List of speech coders

System	Codec
GSM 850, 900, 1 800, 1 900	AMR-WB (Recommendation ITU-T G.722.2) @ 12,65 kbit/s [17]
UMTS (WCDMA), VoLTE	AMR-WB (Recommendation ITU-T G.722.2) @ 12,65 kbit/s [17]
EVS (13,2 kbit/s) [22]	
Over the top solutions (OTT)	Recommendation ITU-T G.722 [4] Recommendation ITU-T G.722.2 [17] Recommendation ITU-T G.729.1 [5] Recommendation ITU-T G.711.1 [16]

The objective is to minimize the impact of transcodings on the quality. Care should also be taken to avoid as far as possible to cascade different speech processing.

7.2 void

7.3 Objective listening Quality in send and receive direction

7.3.1 Objective listening speech quality MOS-LQO in send direction

The listening speech quality tests are conducted under clean network conditions.

Requirements

The requirements for the listening speech quality are as follows:

Table 7.2

Speech coder	MOS-LQOS (P.863)	MOS-LQOM (TOSQA 2001)
AMR-WB (Recommendation ITU-T G.722.2)@12,65 kbit/s [17]	(ffs)	(ffs)
AMR-WB (Recommendation ITU-T G.722.2) @12,65 kbit/s [17]	(ffs)	(ffs)
EVS (13,2 kbit/s) [22]	(ffs)	(ffs)
Recommendation ITU-T G.722 [4]	(ffs)	(ffs)
Recommendation ITU-T G.722.2 [17]	(ffs)	(ffs)
Recommendation ITU-T G.729.1 [5]	(ffs)	(ffs)
Recommendation ITU-T G.711.1 [16]		

NOTE 1: Not sufficient experience is available so far with Recommendation ITU-T P.863 [24] and TOSQA 2001 (ETSI EG 201 377-1 [i.2]) for measuring handsfree terminals. Therefore the numbers for MOS-LQOs and MOS-LQOm are for further study.

Measurement method

Objective listening speech quality is measured using Recommendation ITU-T P.863 [24] in superwideband mode.

The test signal to be used for the measurements shall be 4 sentence pairs (male/female) fulfilling the requirements of Recommendation ITU-T P.863.1 [25]. The 4 sentence pairs are taken from Recommendation ITU-T P.501 [12]. It shall be stated, which sentence pairs were used. The test signal level is averaged over all sentence pairs (4 sentence pairs). The measurement is done 4 times, every time using another pair of the speech sentences. The result of the measurement is the averaged value of all 4 measurements.

NOTE 2: For the use of P.863 the following applies (see Recommendation ITU-T P.863.1 [25]):

- Superwideband Context (MOS-LQOS):
 - Reference Signal Superwideband flat filtered 50 Hz to 14 kHz.
 - Test Signal Superwideband flat filtered 50 Hz to 14 kHz.

NOTE 3: An alternative test method is TOSQA 2001 (ETSI EG 201 377-1 [i.2]). With TOSQA, terminals used in narrowband and wideband mode should be measured based on MOS-LQOm.

7.3.2 Objective listening quality MOS-LQO in receive direction

The listening speech quality tests are conducted under clean network conditions as well as with network impairments simulated. In addition to the listening speech quality tests the delay is measured.

Requirements

The requirement for the listening speech quality and the delay under clean network conditions are as follows.

Table 7.3

Speech coder	MOS-LQOS (P.863)	MOS-LQOM (TOSQA 2001)
AMR-WB (Recommendation ITU-T G.722.2) @12,65 kbit/s [17]	(ffs)	(ffs)
AMR-WB (Recommendation ITU-T G.722.2) @12,65 kbit/s [17]	(ffs)	(ffs)
EVS (13,2 kbit/s) [22]	(ffs)	(ffs)
Recommendation ITU-T G.722 [4]	(ffs)	(ffs)
Recommendation ITU-T G.722.2 [17]	(ffs)	(ffs)
Recommendation ITU-T G.729.1 [5]	(ffs)	(ffs)
Recommendation ITU-T G.711.1 [16]		

NOTE 1: Not sufficient experience is available so far with Recommendation ITU-T P.863 [24] and TOSQA 2001 (ETSI EG 201 377-1 [i.2]) for measuring handsfree terminals. Therefore the numbers for MOS-LQOS and MOS-LQOM are for further study.

Measurement method

Objective listening speech quality is measured using Recommendation ITU-T P.863 [24] in superwideband mode.

The test signal to be used for the measurements shall be 4 sentence pairs (male/female) fulfilling the requirements of Recommendation ITU-T P.863.1 [25]. The 4 sentence pairs are taken from Recommendation ITU-T P.501 [12]. It shall be stated, which sentence pairs were used. The test signal level is averaged over all sentence pairs (4 sentence pairs). The measurement is done 4 times, every time using another pair of the speech sentences. The result of the measurement is the averaged value of all 4 measurements.

NOTE 2: For the use of P.863 the following applies (see Recommendation ITU-T P.863.1 [25]):

- Superwideband Context (MOS-LQOS):
 - Reference Signal Superwideband flat filtered 50 Hz to 14 kHz.
 - Test Signal Wideband flat low pass filtered 7,8 kHz.

NOTE 3: An alternative test method is TOSQA 2001 (ETSI EG 201 377-1 [i.2]). With TOSQA, terminals used in narrowband and wideband mode should be measured based on MOS-LQOM.

For the performance tests with network impairments the following settings are used.

7.4 Network conditions for electrical-acoustical measurements (speech samples)

For further study.

8 Requirements and associated Measurement Methodologies (with an additional radio link between the terminal and external electroacoustical devices)

The intention is to provide requirements and test methods for the complete chain.
