## Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for ETSI members and non-members, and can be found in SR 000 314: "Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (http://www.etsi.org/ipr).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in SR 000314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

## Foreword

This Technical Specification (TS) has been produced by the ETSI $3^{\text {rd }}$ Generation Partnership Project (3GPP).
The present document may refer to technical specifications or reports using their 3GPP identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables. The mapping of document identities is as follows:

For 3GPP documents:
3G TS |TR nn.nnn "<title>" (with or without the prefix 3G)
is equivalent to
ETSI TS | TR 1nn nnn "[Digital cellular telecommunications system (Phase 2+) (GSM);] Universal Mobile
Telecommunications System; <title>
For GSM document identities of type "GSM xx.yy", e.g. GSM 01.04, the corresponding ETSI document identity may be found in the Cross Reference List on www.etsi.org/key

## Foreword

This Technical Specification has been produced by the 3GPP.
The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of this TS, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version 3.y.z
where:
$x$ the first digit:
1 presented to TSG for information;
2 presented to TSG for approval;
3 Indicates TSG approved document under change control.
y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.
z the third digit is incremented when editorial only changes have been incorporated in the specification;

## 1 Scope

The present document describes multiplexing, channel coding and interleaving for UTRA Physical Layer TDD mode.

## 2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies.

## 3 Definitions, symbols and abbreviations

### 3.1 Definitions

For the purposes of the present document, the [following] terms and definitions [given in ... and the following] apply.
TrCH number: Transport channel number represents a TrCH ID assigned to L1 by L2. Transport channels are multiplexed to the CCTrCH in the ascending order of these IDs.

### 3.2 Symbols

For the purposes of the present document, the following symbols apply:

$$
\begin{array}{ll}
\lceil x\rangle & \text { round towards } \infty, \text { i.e. integer such that } x \leq\lceil x\rceil<x+1 \\
\lfloor x\rfloor & \text { round towards }-\infty, \text { i.e. integer such that } x-1<\lfloor x\rfloor \leq x \\
|x| & \text { absolute value of } x
\end{array}
$$

Unless otherwise is explicitly stated when the symbol is used, the meaning of the following symbols are:

| $i$ | TrCH number |
| :--- | :--- |
| $j$ | TFC number |
| $k$ | Bit number |
| $l$ | TF number |
| $m$ | Transport block number |
| $n$ | Radio frame number |
| $p$ | PhCH number |
| r | Code block number |
| $I$ | Number of TrCHs in a CCTrCH. |
| $C_{i}$ | Number of code blocks in one TTI of TrCH $i$. |
| $F_{i}$ | Number of radio frames in one TTI of TrCH $i$. |
| $M_{i}$ | Number of transport blocks in one TTI of TrCH $i$. |
| $P$ | Number of PhCHs used for one CCTrCH. |
| $P L$ | Puncturing Limit for the uplink. Signalled from higher layers |
| $R M_{i}$ | Rate Matching attribute for TrCH $i$. Signalled from higher layers. |

Temporary variables, i.e. variables used in several (sub)sections with different meaning.
$\mathrm{x}, \mathrm{X}$
y, Y
z, Z

### 3.3 Abbreviations

For the purposes of the present document, the following abbreviations apply:

| <ACRONYM> | <Explanation> |
| :--- | :--- |
| ARQ | Automatic Repeat on Request |
| BCH | Broadcast Channel |
| BER | Bit Error Rate |
| BS | Base Station |
| BSS | Base Station Subsystem |
| CBR | Constant Bit Rate |
| CCCH | Common Control Channel |
| CCTrCH | Coded Composite Transport Channel |
| CDMA | Code Division Multiple Access |
| CRC | Cyclic Redundancy Check |
| DCA | Dynamic Channel Allocation |
| DCCH | Dedicated Control Channel |
| DCH | Dedicated Channel |
| DL | Downlink |
| DRX | Discontinuous Reception |
| DSCH | Downlink Shared Channel |
| DTX | Discontinuous Transmission |
| FACH | Forward Access Channel |
| FDD | Frequency Division Duplex |
| FDMA | Frequency Division Multiple Access |
| FEC | Forward Error Control |
| FER | Frame Error Rate |
| GF | Galois Field |
| JD | Joint Detection |
| L1 | Layer 1 |
| L2 | Layer 2 |
| LLC | Logical Link Control |
| MA | Multiple Access |
| MAC | Medium Access Control |
| MS | Mobile Station |
| MT | Mobile Terminated |
| NRT | Non-Real Time |
|  |  |

| OVSF | Orthogonal Variable Spreading Factor |
| :--- | :--- |
| PC | Power Control |
| PCCC | Parallel Concatenated Convolutional Code |
| PCH | Paging Channel |
| PhCH | Physical Channel |
| PI | Paging Indicator |
| QoS | Quality of Service |
| QPSK | Quaternary Phase Shift Keying |
| RACH | Random Access Channel |
| RF | Radio Frequency |
| RLC | Radio Link Control |
| RRC | Radio Resource Control |
| RRM | Radio Resource Management |
| RSC | Recursive Systematic Convolutional Coder |
| RT | Real Time |
| RU | Resource Unit |
| SCCC | Serial Concatenated Convolutional Code |
| SCH | Synchronization Channel |
| SNR | Signal to Noise Ratio |
| TCH | Traffic channel |
| TDD | Time Division Duplex |
| TDMA | Time Division Multiple Access |
| TFC | Transport Format Combination |
| TFCI | Transport Format Combination Indicator |
| TPC | Transmit Power Control |
| TrBk | Transport Block |
| TrCH | Transport Channel |
| TTI | Transmission Time Interval |
| UE | User Equipment |
| UL | Uplink |
| UMTS | Universal Mobile Telecommunications System |
| USCH | Uplink Shared Channel |
| UTRA | UMTS Terrestrial Radio Access |
| VBR | Variable Bit Rate |
|  |  |

## 4 Multiplexing, channel coding and interleaving

### 4.1 General

Data stream from/to MAC and higher layers (Transport block / Transport block set) is encoded/decoded to offer transport services over the radio transmission link. Channel coding scheme is a combination of error detection, error correcting (including rate matching), and interleaving and transport channels mapping onto/splitting from physical channels.

In the UTRA-TDD mode, the total number of basic physical channels (a certain time slot one spreading code on a certain carrier frequency) per frame is given by the maximum number of time slots which is 15 and the maximum number of CDMA codes per time slot.

### 4.2 Transport channel coding/multiplexing

Figure 4-1 illustrates the overall concept of transport-channel coding and multiplexing. Data arrives to the coding/multiplexing unit in form of transport block sets, once every transmission time interval. The transmission time interval is transport-channel specific from the set $\{10 \mathrm{~ms}, 20 \mathrm{~ms}, 40 \mathrm{~ms}, 80 \mathrm{~ms}\}$.

The following coding/multiplexing steps can be identified:

- Add CRC to each transport block (see section 4.2.1)
- TrBk concatenation / Code block segmentation (see section 4.2.2)
- Channel coding (see section 4.2.3)
- Radio frame size equalization (see section 4.2.4)
- Interleaving (two steps, see sections 4.2.5 and 4.2.10)
- Radio frame segmentation (4.2.6)
- Rate matching (see section 4.2.7)
- Multiplexing of transport channels (see section 4.2.8)
- Physical channel segmentation (see section 4.2.9)
- Mapping to physical channels (see section 4.2.11)

The coding/multiplexing steps for uplink and downlink are shown in figure 4-1.

Figure 4-1: Transport channel multiplexing structure for uplink and downlink

Primarily, transport channels are multiplexed as described above, i.e. into one data stream mapped on one or several physical channels. However, an alternative way of multiplexing services is to use multiple CCTrCHs (Coded Composite Transport Channels), which corresponds to having several parallel multiplexing chains as in figure $4-1$, resulting in several data streams, each mapped to one or several physical channels.

### 4.2.1 Error detection

Error detection is provided on transport blocks through a Cyclic Redundancy Check. The CRC is $24,16,12,8$ or 0 bits and it is signalled from higher layers what CRC length that should be used for each transport channel.

### 4.2.1.1 CRC calculation

The entire transport block is used to calculate the CRC parity bits for each transport block. The parity bits are generated by one of the following cyclic generator polynomials:

$$
\begin{aligned}
& g_{C R C 24}(D)=D^{24}+D^{23}+D^{6}+D^{5}+D+1 \\
& g_{C R C 16}(D)=D^{16}+D^{12}+D^{5}+1 \\
& g_{C R C 12}(D)=D^{12}+D^{11}+D^{3}+D^{2}+D+1 \\
& g_{C R C 8}(D)=D^{8}+D^{7}+D^{4}+D^{3}+D+1
\end{aligned}
$$

Denote the bits in a transport block delivered to layer 1 by $a_{i m 1}, a_{i m 2}, a_{i m 3}, \ldots, a_{i m A_{i}}$, and the parity bits by
$p_{i m 1}, p_{i m 2}, p_{i m 3}, \ldots, p_{i m L_{i}} . A_{i}$ is the length of a transport block of $\operatorname{TrCH} i, m$ is the transport block number, and $L_{i}$ is 24, 16,8 , or 0 depending on what is signalled from higher layers.

The encoding is performed in a systematic form, which means that in $\mathrm{GF}(2)$, the polynomial

$$
a_{i m 1} D^{A_{i}+23}+a_{i m 2} D^{A_{i}+22}+\ldots+a_{i m A_{i}} D^{24}+p_{i m 1} D^{23}+p_{i m 2} D^{22}+\ldots+p_{i m 23} D^{1}+p_{i m 24}
$$

yields a remainder equal to 0 when divided by $g_{\text {CRC24 }}(D)$, polynomial

$$
a_{i m 1} D^{A_{i}+15}+a_{i m 2} D^{A_{i}+14}+\ldots+a_{i m A_{i}} D^{16}+p_{i m 1} D^{15}+p_{i m 2} D^{14}+\ldots+p_{i m 15} D^{1}+p_{i m 16}
$$

yields a remainder equal to 0 when divided by $g_{C R C 16}(D)$, polynomial

$$
a_{i m 1} D^{A_{i}+11}+a_{i m 2} D^{A_{i}+10}+\ldots+a_{i m A_{i}} D^{12}+p_{i m 1} D^{11}+p_{i m 2} D^{10}+\ldots+p_{i m 7} D^{1}+p_{i m 12}
$$

yields a remainder equal to 0 when divided by $\mathrm{g}_{\mathrm{CRC12}}(\mathrm{D})$ and the polynomial

$$
a_{i m 1} D^{A_{i}+7}+a_{i m 2} D^{A_{i}+6}+\ldots+a_{i m A_{i}} D^{8}+p_{i m 1} D^{7}+p_{i m 2} D^{6}+\ldots+p_{i m 7} D^{1}+p_{i m 8}
$$

yields a remainder equal to 0 when divided by $g_{\text {CRC } 8}(D)$.

### 4.2.1.2 Relation between input and output of the Cyclic Redundancy Check

The bits after CRC attachment are denoted by $b_{i m 1}, b_{i m 2}, b_{i m 3}, \ldots, b_{i m B_{i}}$, where $B_{i}=A_{i}+L_{i}$. The relation between $a_{i m k}$ and $b_{i m k}$ is:

$$
\begin{aligned}
& b_{i m k}=a_{i m k} \quad k=1,2,3, \ldots, A_{i} \\
& b_{i m k}=p_{i m\left(L_{i}+1-\left(k-A_{i}\right)\right)} \quad k=A_{i}+1, A_{i}+2, A_{i}+3, \ldots, A_{i}+L_{i}
\end{aligned}
$$

### 4.2.2 Transport block concatenation and code block segmentation

All transport blocks in a TTI are serially concatenated. If the number of bits in a TTI is larger than the maximum size of a code block, then code block segmentation is performed after the concatenation of the transport blocks. The maximum size of the code blocks depends on whether convolutional, turbo coding or no coding is used for the TrCH .

### 4.2.2.1 Concatenation of transport blocks

The bits input to the transport block concatenation are denoted by $b_{i m 1}, b_{i m 2}, b_{i m 3}, \ldots, b_{i m B_{i}}$ where $i$ is the $\operatorname{TrCH}$ number, $m$ is the transport block number, and $B_{i}$ is the number of bits in each block (including CRC). The number of transport blocks on $\operatorname{TrCH} i$ is denoted by $M_{i}$. The bits after concatenation are denoted by $x_{i 1}, x_{i 2}, x_{i 3}, \ldots, x_{i X_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $X_{i}=M_{i} B_{i}$. They are defined by the following relations:

$$
\begin{aligned}
& x_{i k}=b_{i 1 k} \quad k=1,2, \ldots, B_{i} \\
& x_{i k}=b_{i, 2,\left(k-B_{i}\right)} \quad k=B_{i}+1, B_{i}+2, \ldots, 2 B_{i} \\
& x_{i k}=b_{i, 3,\left(k-2 B_{i}\right)} k=2 B_{i}+1,2 B_{i}+2, \ldots, 3 B_{i} \\
& \ldots \\
& x_{i k}=b_{i, M_{i},\left(k-\left(M_{i}-1\right) B_{i}\right)} k=\left(M_{i}-1\right) B_{i}+1,\left(M_{i}-1\right) B_{i}+2, \ldots, M_{i} B_{i}
\end{aligned}
$$

### 4.2.2.2 Code block segmentation

NOTE: It is assumed that filler bits are set to 0 .
Segmentation of the bit sequence from transport block concatenation is performed if $X_{i}>Z$. The code blocks after segmentation are of the same size. The number of code blocks on $\mathrm{TrCH} i$ is denoted by $C_{i}$. If the number of bits input to the segmentation, $X_{i}$, is not a multiple of $C_{i}$, filler bits are added to the last block. The filler bits are transmitted and they are always set to 0 . The maximum code block sizes are:
convolutional coding: $Z=504$
turbo coding: $Z=5114$
no channel coding: $Z=$ unlimited
The bits output from code block segmentation are denoted by $o_{i r 1}, o_{i r 2}, o_{i r 3}, \ldots, o_{i r K_{i}}$, where $i$ is the $\operatorname{TrCH}$ number, $r$ is the code block number, and $K_{i}$ is the number of bits.

Number of code blocks: $C_{i}=\left\lceil X_{i} / Z\right\rceil$
Number of bits in each code block: $K_{i}=\left\lceil X_{i} / C_{i}\right\rceil$
Number of filler bits: $Y_{i}=C_{i} K_{i}-X_{i}$
If $X_{i} \leq Z$, then $o_{i 1 k}=x_{i k}$, and $K_{i}=X_{i}$.
If $X_{i} \geq Z$, then

$$
\begin{aligned}
& o_{i 1 k}=x_{i k} \quad k=1,2, \ldots, K_{i} \\
& o_{i 2 k}=x_{i,\left(k+K_{i}\right)} \quad k=1,2, \ldots, K_{i} \\
& o_{i 3 k}=x_{i,\left(k+2 K_{i}\right)} \quad k=1,2, \ldots, K_{i}
\end{aligned}
$$

$$
\begin{aligned}
& o_{i C_{i} k}=x_{i\left(k+\left(C_{i}-1\right) K_{i}\right)} \quad k=1,2, \ldots, K_{i}-Y_{i} \\
& o_{i C_{i} k}=0 k=\left(K_{i}-Y_{i}\right)+1,\left(K_{i}-Y_{i}\right)+2, \ldots, K_{i}
\end{aligned}
$$

### 4.2.3 Channel coding

Code blocks are delivered to the channel coding block. They are denoted by $o_{i r 1}, o_{i r 2}, o_{i r 3}, \ldots, o_{i r K_{i}}$, where $i$ is the TrCH number, $r$ is the code block number, and $K_{i}$ is the number of bits in each code block. The number of code blocks on $\operatorname{TrCH} i$ is denoted by $C_{i}$. After encoding the bits are denoted by $y_{i r 1}, y_{i r 2}, y_{i r 3}, \ldots, y_{i r Y_{i}}$. The encoded blocks are serially multiplexed so that the block with lowest index $r$ is output first from the channel coding block. The bits output are denoted by $c_{i 1}, c_{i 2}, c_{i 3}, \ldots, c_{i E_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $E_{i}=C_{i} Y_{i}$. The output bits are defined by the following relations:

$$
\begin{aligned}
& c_{i k}=y_{i 1 k} \quad k=1,2, \ldots, Y_{i} \\
& c_{i k}=y_{i, 2,\left(k-Y_{i}\right)} \quad k=Y_{i}+1, Y_{i}+2, \ldots, 2 Y_{i} \\
& c_{i k}=y_{i, 3,\left(k-2 Y_{i}\right)} k=2 Y_{i}+1,2 Y_{i}+2, \ldots, 3 Y_{i} \\
& \ldots \\
& c_{i k}=y_{i, C_{i},\left(k-\left(C_{i}-1\right) Y_{i}\right)} \quad k=\left(C_{i}-1\right) Y_{i}+1,\left(C_{i}-1\right) Y_{i}+2, \ldots, C_{i} Y_{i}
\end{aligned}
$$

The relation between $O_{i r k}$ and $Y_{i r k}$ and between $K_{i}$ and $Y_{i}$ is dependent on the channel coding scheme.
The following channel coding schemes can be applied to transport channels:

- Convolutional coding
- Turbo coding
- No channel coding

The values of $Y_{i}$ in connection with each coding scheme:

- Convolutional coding, $1 / 2$ rate: $\mathrm{Y}_{\mathrm{i}}=2 * \mathrm{~K}_{\mathrm{i}}+16 ; 1 / 3$ rate: $\mathrm{Y}_{\mathrm{i}}=3 * \mathrm{~K}_{\mathrm{i}}+24$
- Turbo coding, $1 / 3$ rate: $\mathrm{Y}_{\mathrm{i}}=3 * \mathrm{~K}_{\mathrm{i}}+12$
- No channel coding, $\mathrm{Y}_{\mathrm{i}}=\mathrm{K}_{\mathrm{i}}$

Table 4.2.3-1: Error Correction Coding Parameters

| Transport channel type | Coding scheme |  |
| :--- | :--- | :--- |
| Coding rate |  |  |
|  |  |  |
|  | Convolutional code | $1 / 2$ |
|  |  |  |
| RACH |  | $1 / 3,1 / 2$ |
| DCH, DSCH, USCH | Turbo code | $1 / 3$ |
|  | No coding |  |

### 4.2.3.1 Convolutional Coding

- Constraint length $K=9$. Coding rates $1 / 2$ and $1 / 3$.
- The configuration of the convolutional coder is presented in figure 4-2.
- The output from the convolutional coder shall be done in the order output0, output1,output2, output0, output $1, \ldots$, output 2 . (When coding rate is $1 / 2$, output is done up to output 1 ).
- The initial value of the shift register of the coder shall be "all 0".
- K-1 tail bits (value 0 ) shall be added to the end of the code block before encoding.

Figure 4-2: Convolutional Coder

### 4.2.3.2 Turbo coding

### 4.2.3.2.1 Turbo coder

For data services requiring quality of service between $10^{-3}$ and $10^{-6} \mathrm{BER}$ inclusive, parallel concatenated convolutional code (PCCC) with 8 -state constituent encoders is used.

The transfer function of the 8 -state constituent code for PCCC is

$$
\mathrm{G}(\mathrm{D})=\left[1, \frac{n(D)}{d(D)}\right]
$$

where,

$$
\begin{aligned}
& d(D)=1+D^{2}+D^{3} \\
& n(D)=1+D+D^{3} .
\end{aligned}
$$

Figure 4-3: Structure of the 8 -state PCCC encoder (dotted lines effective for trellis termination only)
The initial value of the shift registers of the PCCC encoder shall be all zeros.
The output of the PCCC encoder is punctured to produce coded bits corresponding to the desired code rate. For rate $1 / 3$, none of the systematic or parity bits are punctured, and the output sequence is $\mathrm{X}(0), \mathrm{Y}(0), \mathrm{Y}^{\prime}(0), \mathrm{X}(1), \mathrm{Y}(1), \mathrm{Y}^{\prime}(1)$, etc.

### 4.2.3.2.2 Trellis termination in turbo code

Trellis termination is performed by taking the tail bits from the shift register feedback after all information bits are encoded. Tail bits are added after the encoding of information bits.

The first three tail bits shall be used to terminate the first constituent encoder (upper switch of figure 4-3 in lower position) while the second constituent encoder is disabled. The last three tail bits shall be used to terminate the second constituent encoder (lower switch of figure 4-3 in lower position) while the first constituent encoder is disabled.

The transmitted bits for trellis termination shall then be

$$
X(t) Y(t) X(t+1) Y(t+1) X(t+2) Y(t+2) X^{\prime}(t) Y^{\prime}(t) X^{\prime}(t+1) Y^{\prime}(t+1) X^{\prime}(t+2) Y^{\prime}(t+2)
$$

### 4.2.3.2.3 Turbo code internal interleaver

Figure 4-4 depicts the overall 8-State PCCC Turbo coding scheme including Turbo code internal interleaver. The Turbo code internal interleaver consists of mother interleaver generation and pruning. For arbitrary given block length K , one mother interleaver is selected from the 134 mother interleavers set. The generation scheme of mother interleaver is described in section 4.2.3.2.3.1. After the mother interleaver generation, $l$-bits are pruned in order to adjust the mother interleaver to the block length K . Tail bits $\mathrm{T}_{1}$ and $\mathrm{T}_{2}$ are added for constituent encoders RSC1 and RSC2, respectively. The definition of $l$ is shown in section 4.2.3.2.3.2..

Figure 4-4: Overall 8 State PCCC Turbo Coding

### 4.2.3.2.3.1 Mother interleaver generation

The interleaving consists of three stages. In first stage, the input sequence is written into the rectangular matrix row by row. The second stage is intra-row permutation. The third stage is inter-row permutation. The three-stage permutations are described as follows, the input block length is assumed to be K ( 320 to 5114 bits).

## First Stage:

(1) Determine the number of rows $R$ such that
$\mathrm{R}=10(\mathrm{~K}=481$ to 530 bits; Case-1)
$\mathrm{R}=20(\mathrm{~K}=$ any other block length except 481 to 530 bits; Case-2)
(2) Determine the number of columns C such that

Case-1; $\mathbf{C}=p=53$
Case-2;
(i) find minimum prime p such that,

$$
0=<(\mathrm{p}+1)-\mathrm{K} / \mathrm{R}
$$

(ii) if $\quad(0=<\mathrm{p}-\mathrm{K} / \mathrm{R})$ then go to (iii)
else $C=p+1$.
(iii) if $(0=<\mathrm{p}-1-\mathrm{K} / \mathrm{R})$ then $\mathrm{C}=\mathrm{p}-1$.

Else $\mathrm{C}=\mathrm{p}$.
(3) The input sequence of the interleaver is written into the RxC rectangular matrix row by row starting from row 0 .

## Second Stage:

A. If $\mathrm{C}=p$
(A-1) Select a primitive root $\mathrm{g}_{0}$ from table 4.2.2-2.
(A-2) Construct the base sequence $c(i)$ for intra-row permutation as:

$$
c(i)=\left[g_{0} \times c(i-1)\right] \bmod p, \mathrm{i}=1,2, \ldots(p-2) ., \mathrm{c}(0)=1 .
$$

(A-3) Select the minimum prime integer set $\left\{q_{\mathrm{j}}\right\}$ ( $\mathrm{j}=1,2, \ldots \mathrm{R}-1$ ) such that

$$
\begin{aligned}
& \text { g.c.d }\left\{q_{\mathrm{j}}, p-1\right\}=1 \\
& \mathrm{q}_{\mathrm{j}}>6 \\
& \mathrm{q}_{\mathrm{j}}>\mathrm{q}_{(\mathrm{j}-1)}
\end{aligned}
$$

where g.c.d. is greatest common divider. And $q_{0}=1$.
(A-4) The set $\left\{q_{j}\right\}$ is permuted to make a new set $\left\{p_{j}\right\}$ such that

$$
p_{\mathrm{P}(j)}=q_{j}, j=0,1, \ldots . \mathrm{R}-1,
$$

where $\mathrm{P}(j)$ is the inter-row permutation pattern defined in the third stage.
(A-5) Perform the j -th $(\mathrm{j}=0,1,2, \ldots, \mathrm{C}-1)$ intra-row permutation as:

$$
c_{j}(i)=c\left(\left[i \times p_{j}\right] \bmod (p-1)\right), \quad \mathrm{i}=0,1,2, \ldots,(p-2) ., \text { and } \mathrm{c}_{\mathrm{j}}(p-1)=0,
$$

where $c_{j}(\mathrm{i})$ is the input bit position of i -th output after the permutation of j -th row.
If $\mathrm{C}=p+1$
(B-1) Same as case A-1.
(B-2) Same as case A-2.
(B-3) Same as case A-3.
(B-4) Same as case A-4.
(B-5) Perform the $j$-th $(j=0,1,2, \ldots, \mathrm{R}-1)$ intra-row permutation as:

$$
c_{j}(i)=c\left(\left[i \times p_{j}\right] \bmod (p-1)\right), \quad i=0,1,2, \ldots,(p-2) ., c_{j}(p-1)=0, \text { and } c_{j}(p)=p
$$

where $c_{j}(i)$ is the input bit position of $i$-th output after the permutation of $j$-th row.
(B-6) If $(\mathrm{K}=\mathrm{C} \times \mathrm{R})$ then exhange $c_{R-I}(p)$ with $c_{R-I}(0)$.

## If $\mathrm{C}=\mathrm{p}-1$

(C-1) Same as case A-1.
(C-2) Same as case A-2.
(C-3) Same as case A-3.
(C-4) Same as case A-4.
(C-5) Perform the $j$-th $(j=0,1,2, \ldots, \mathrm{R}-1)$ intra-row permutation as: $c_{j}(i)=c\left(\left[i \times p_{j}\right] \bmod (p-1)\right)-1, \quad i=0,1,2, \ldots,(p-2) .$,
where $c_{j}(i)$ is the input bit position of $i$-th output after the permutation of $j$-th row.

## Third Stage:

Perform the inter-row permutation based on the following $\mathrm{P}(j)(j=0,1, \ldots, \mathrm{R}-1)$ patterns, where $\mathrm{P}(j)$ is the original row position of the $j$-th permuted row.
$P_{A}:\{19,9,14,4,0,2,5,7,12,18,10,8,13,17,3,1,16,6,15,11\}$ for $R=20$
$P_{B}:\{19,9,14,4,0,2,5,7,12,18,16,13,17,15,3,1,6,11,8,10\}$ for $R=20$
$P_{C}:\{9,8,7,6,5,4,3,2,1,0\}$ for $R=10$
The usage of these patterns is as follows:
Block length K: $\mathrm{P}(j)$
320 to 480-bit: $\quad \mathrm{P}_{\mathrm{A}}$
481 to 530-bit: $\quad \mathrm{P}_{\mathrm{C}}$
531 to 2280 -bit: $\mathrm{P}_{\mathrm{A}}$
2281 to 2480-bit: $\quad P_{B}$
2481 to 3160-bit: $\quad P_{A}$
3161 to 3210-bit: $\quad P_{B}$
3211 to 5114-bit: $\quad P_{A}$
(2) The output of the mother interleaver is the sequence read out column by column from the permuted $\mathrm{R} \times \mathrm{C}$ matrix starting from column 0 .

### 4.2.3.2.3.2 Definition of the number of pruning bits

The output of the mother interleaver is pruned by deleting the $l$-bits in order to adjust the mother interleaver to the block length K , where the deleted bits are non-existent bits in the input sequence. The pruning bits number $l$ is defined as:

$$
1=\mathrm{R}^{\times} \mathrm{C}-\mathrm{K},
$$

where R is the row number and C is the column number defined in section 4.2.3.2.3.1.

### 4.2.4 Radio frame size equalisation

Radio frame size equalisation is padding the input bit sequence in order to ensure that the output can be segmented in $F_{i}$ data segments of same size as described in the section 4.2.6.

The input bit sequence to the radio frame size equalisation is denoted by $c_{i 1}, c_{i 2}, c_{i 3}, \ldots, c_{i E_{i}}$, where $i$ is $\operatorname{TrCH}$ number and $E_{i}$ the number of bits. The output bit sequence is denoted by $t_{i 1}, t_{i 2}, t_{i 3}, \ldots, t_{i T_{i}}$, where $T_{i}$ is the number of bits. The output bit sequence is derived as follows:
$t_{i k}=c_{i k}$, for $\mathrm{k}=1 \ldots E_{i}$ and
$t_{i k}=\{0 \mid 1\}$ for $\mathrm{k}=E_{i}+1 \ldots T_{i}$, if $E_{i}<T_{i}$
where
$\mathrm{T}_{i}=F_{i} * N_{i}$ and
$N_{i}=\left\lfloor\left(E_{i}-1\right) / F_{i}\right\rfloor+1$ is the number of bits per segment after size equalisation.

### 4.2.5 1st interleaving

The $1^{\text {st }}$ interleaving is a block interleaver with inter-column permutations. The input bit sequence to the $1^{\text {st }}$ interleaver is denoted by $x_{i 1}, x_{i 2}, x_{i 3}, \ldots, x_{i X_{i}}$, where $i$ is $\operatorname{TrCH}$ number and $X_{i}$ the number of bits (at this stage $X_{i}$ is assumed and guaranteed to be an integer multiple of TTI). The output bit sequence is derived as follows:

1) Select the number of columns $C_{I}$ from table 4.2.5-1.
2) Determine the number of rows $R_{I}$ defined as $R_{I}=X_{i} / C_{I}$
3) Write the input bit sequence into the $R_{I} \times C_{I}$ rectangular matrix row by row starting with bit $x_{i, 1}$ in the first column of the first row and ending with bit $x_{i,\left(R_{I} C_{I}\right)}$ in column $C_{I}$ of row $R_{I}$ :

$$
\left[\begin{array}{ccclc}
x_{i 1} & x_{i 2} & x_{i 3} & \ldots & x_{i C_{I}} \\
x_{i,\left(C_{I}+1\right)} & x_{i,\left(C_{I}+2\right)} & x_{i,\left(C_{I}+3\right)} & \ldots x_{i,\left(2 C_{I}\right)} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
x_{i,\left(\left(R_{I}-1\right) C_{I}+1\right)} & x_{i,\left(\left(R_{I}-1\right) C_{I}+2\right)} & x_{i,\left(\left(R_{I}-1\right) C_{I}+3\right)} & \ldots x_{i,\left(R_{I} C_{I}\right)}
\end{array}\right]
$$

4) Perform the inter-column permutation based on the pattern $\left\{\mathrm{P}_{1}(j)\right\}(j=0,1, \ldots, \mathrm{C}-1)$ shown in table 4.2.5-1, where $\mathrm{P}_{1}(j)$ is the original column position of the $j$-th permuted column. After permutation of the columns, the bits are denoted by $y_{i k}$ :

$$
\left[\begin{array}{ccclc}
y_{i 1} & y_{i,\left(R_{I}+1\right)} & y_{i,\left(2 R_{I}+1\right)} & \ldots y_{i,\left(\left(C_{I}-1\right) R_{I}+1\right)} \\
y_{i 2} & y_{i,\left(R_{I}+2\right)} & y_{i,\left(2 R_{I}+2\right)} & \ldots y_{i,\left(\left(C_{I}-1\right) R_{I}+2\right)} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
y_{i R_{I}} & y_{i,\left(2 R_{I}\right)} & y_{i,\left(3 R_{I}\right)} & \ldots & y_{i,\left(C_{I} R_{I}\right)}
\end{array}\right]
$$

5) Read the output bit sequence $y_{i 1}, y_{i 2}, y_{i 3}, \ldots, y_{i,\left(C_{I} R_{I}\right)}$ of the $1^{\text {st }}$ interleaving column by column from the intercolumn permuted $R_{I} \times C_{I}$ matrix. Bit $y_{i, 1}$ corresponds to the first row of the first column and bit $y_{i,\left(R_{I} C_{I}\right)}$ corresponds to row $R_{I}$ of column $C_{I}$.

The bits input to the $1^{\text {st }}$ interleaving are denoted by $t_{i 1}, t_{i 2}, t_{i 3}, \ldots, t_{i T_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $T_{i}$ the number of bits. Hence, $x_{i k}=t_{i k}$ and $X_{i}=T_{i}$.

The bits output from the $1^{\text {st }}$ interleaving are denoted by $d_{i 1}, d_{i 2}, d_{i 3}, \ldots, d_{i T_{i}}$, and $\mathrm{d}_{i k}=y_{i k}$.
Table 4.2.5-1

| TTI | Number of columns C ${ }_{1}$ | Inter-column permutation patterns |
| :---: | :---: | :---: |
| 10 ms | 1 | $\{0\}$ |
| 20 ms | 2 | $\{0,1\}$ |
| 40 ms | 4 | $\{0,2,1,3\}$ |
| 80 ms | 8 | $\{0,4,2,6,1,5,3,7\}$ |

### 4.2.6 Radio frame segmentation

When the transmission time interval is longer than 10 ms , the input bit sequence is segmented and mapped onto consecutive radio frames. Following radio frame size equalisation the input bit sequence length is guaranteed to be an integer multiple of $F_{i}$.

The input bit sequence is denoted by $x_{i 1}, x_{i 2}, x_{i 3}, \ldots, x_{i X_{i}}$ where $i$ is the $\operatorname{TrCH}$ number and $X_{i}$ is the number bits. The $F i$ output bit sequences per TTI are denoted by $y_{i, n_{i} 1}, y_{i, n_{i} 2}, y_{i, n_{i} 3}, \ldots, y_{i, n_{i} Y_{i}}$ where $n_{i}$ is the radio frame number in current TTI and $Y_{i}$ is the number of bits per radio frame for $\operatorname{TrCH} i$. The output sequences are defined as follows:

$$
y_{i, n_{i} k}=x_{i,\left(\left(n_{i}-1\right) Y_{i}\right)+k}, n_{i}=1 \ldots F_{i}, k=1 \ldots Y_{i}
$$

where
$Y_{i}=\left(X_{i} / F_{i}\right)$ is the number of bits per segment,
$x_{i k}$ is the $\mathrm{k}^{\text {th }}$ bit of the input bit sequence and
$y_{i, n_{i} k}$ is the $\mathrm{k}^{\text {th }}$ bit of the output bit sequence corresponding to the $\mathrm{n}^{\text {th }}$ radio frame
The $n_{i}$-th segment is mapped to the $n_{i}$-th radio frame of the transmission time interval.

The input bit sequence to the radio frame segmentation is denoted by $d_{i 1}, d_{i 2}, d_{i 3}, \ldots, d_{i T_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $T_{i}$ the number of bits. Hence, $x_{i k}=d_{i k}$ and $X_{i}=T_{i}$.

The output bit sequence corresponding radio frame $n_{i}$ is denoted by $e_{i 1}, e_{i 2}, e_{i 3}, \ldots, e_{i N_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $N_{i}$ is the number of bits. Hence, $e_{i, k}=y_{i, n_{i} k}$ and $N_{i}=Y_{i}$.

### 4.2.7 Rate matching

Rate matching means that bits on a TrCH are repeated or punctured. Higher layers assign a rate-matching attribute for each TrCH . This attribute is semi-static and can only be changed through higher layer signalling. The rate-matching attribute is used when the number of bits to be repeated or punctured is calculated.

The number of bits on a TrCH can vary between different transmission time intervals. When the number of bits between different transmission time intervals is changed, bits are repeated to ensure that the total bit rate after TrCH multiplexing is identical to the total channel bit rate of the allocated physical channels.

Notation used in section 4.2.7 and subsections:
$N_{i j}$ : Number of bits in a radio frame before rate matching on $\operatorname{TrCH} i$ with transport format combination $j$.
$\Delta N_{i j}$ : If positive - number of bits to be repeated in each radio frame on $\operatorname{TrCH} i$ with transport format combination $j$.
If negative - number of bits to be punctured in each radio frame on $\operatorname{TrCH} i$ with transport format combination $j$.
$R M_{i}$ : Semi-static rate matching attribute for $\operatorname{TrCH} i$. Signalled from higher layers.
PL: Puncturing limit. This value limits the amount of puncturing that can be applied in order to minimise the number of physical channels. Signalled from higher layers.
$N_{\text {data }, j}$ : Total number of bits that are available for a CCTrCH in a radio frame with transport format combination j .
$P$ : maximum number of physical channels for a CCTrCH .
I: Number of TrCHs in a CCTrCH .
$Z_{m j}$ : Intermediate calculation variable.
$F_{i}: \quad$ Number of radio frames in the transmission time interval of $\operatorname{TrCH} i$.
$n_{i}$ : Radio frame number in the transmission time interval of $\operatorname{TrCH} i\left(0 \leq n_{i}<F_{i}\right)$.
$q$ : Average puncturing or repetition distance(normalised to only show the remaining rate matching on top of an integer number of repetitions).
$I_{F}\left(n_{i}\right)$ : The inverse interleaving function of the $1^{\text {st }}$ interleaver (note that the inverse interleaving function is identical to the interleaving function itself for the $1^{\text {st }}$ interleaver).
$S\left(n_{i}\right)$ : The shift of the puncturing or repetition pattern for radio frame $\mathrm{n}_{\mathrm{i}}$.
$T F_{i}(j)$ : Transport format of TrCH i for the transport format combination j .
TFS( $i$ ): The set of transport format indexes $l$ for TrCH i.
$e_{\text {ini }}$ : $\quad$ Initial value of variable $e$ in the rate matching pattern determination algorithm of section 4.2.7.3.
$e_{\text {plus }} \quad$ Increment of variable $e$ in the rate matching pattern determination algorithm of section 4.2.7.3.
$e_{\text {minus }} \quad$ Decrement of variable $e$ in the rate matching pattern determination algorithm of section 4.2.7.3.
$b: \quad$ Indicates systematic and parity bits.
$b=1$ : Systematic bit. $X(t)$ in 4.2.3.2.1.
$Y: \quad b=2: 1^{\text {st }}$ parity bit (from the upper Turbo constituent encoder). $Y(t)$ in section 4.2.3.2.1.
$Y^{\prime}: \quad b=3: 2^{\text {nd }}$ parity bit (from the lower Turbo constituent encoder). $Y^{\prime}(t)$ in section 4.2.3.2.1.

### 4.2.7.1 Determination of rate matching parameters

The following relations are used when calculating the rate matching pattern:

$$
\begin{aligned}
& Z_{0, j}=0 \\
& Z_{i j}=\left\lfloor\frac{\sum_{m=1}^{i} R M_{m} \cdot N_{m j}}{\sum_{m=1}^{I} R M_{m} \cdot N_{m j}} \cdot N_{d a t a, j}\right\rfloor \quad \text { for all } \mathrm{i}=1 . . \mathrm{I} \\
& \Delta N_{i j}=Z_{i j}-Z_{i-1, j}-N_{i j} \quad \text { for all } \mathrm{i}=1 . . \mathrm{I}
\end{aligned}
$$

Puncturing can be used to minimise the required transmission capacity. The maximum amount of puncturing that can be applied is signalled from higher layers and denoted by PL. The possible values for $\mathrm{N}_{\text {data }}$ depend on the number of physical channels P , allocated to the respective CCTrCH , and on their characteristics (spreading factor, length of midamble and TFCI, usage of TPC and multiframe structure), which is given in [7].

Denote the number of data bits in each physical channel by $N_{k, S k}$, where $k$ refers to the sequence number $l \leq k \leq P$ of this physical channel in the allocation message, and the second index $S k$ indicates the spreading factor with the possible values $\{16,8,4,2,1\}$, respectively. For each physical channel an individual minimum spreading factor $S k_{\min }$ is transmitted by means of the higher layer. Then, for $N_{\text {data }}$ one of the following values in ascending order can be chosen: $\left\{N_{l, 16}, \ldots, N_{l, S l m i n}, N_{l, S l m i n}+N_{2,16}, \ldots, N_{l, S l m i n}+N_{2, S 2 \text { min }}, \ldots, N_{l, S l m i n}+N_{2, S 2 m i n}+\ldots+N_{P, 16}, \ldots, N_{l, S l m i n}+N_{2, S 2 \text { min }}+\ldots+N_{P, S P \text { min }}\right\}$.
$\mathrm{N}_{\text {data, } \mathrm{j}}$ for the transport format combination j is determined by executing the following algorithm:

$$
\begin{aligned}
& \mathrm{SET} 1=\left\{\mathrm{N}_{\mathrm{data}} \text { such that } N_{\text {data }}-P L \cdot \sum_{x=1}^{I} \frac{R M_{x}}{\min _{1 \leq y \leq I}\left\{R M_{y}\right\}} \cdot N_{x, j} \text { is non negative }\right\} \\
& \mathrm{N}_{\mathrm{data}, \mathrm{j}}=\min \text { SET1 }
\end{aligned}
$$

The number of bits to be repeated or punctured, $\Delta \mathrm{N}_{\mathrm{ij}}$, within one radio frame for each TrCHi is calculated with the relations given at the beginning of this section for all possible transport format combinations $j$ and selected every radio frame.

If $\Delta \mathrm{N}_{\mathrm{ij}}=0$ then the output data of the rate matching is the same as the input data and the rate matching algorithm of section 4.2.7.3 does not need to be executed.

Otherwise, the rate matching pattern is calculated with the algorithm described in section 4.2.7.3. For this algorithm the parameters $\mathrm{e}_{\mathrm{ini}}, \mathrm{e}_{\text {plus }}, \mathrm{e}_{\text {minus }}$, and $X_{i}$ are needed, which are calculated according to the equations in section 4.2.7.1.1 and 4.2.7.1.2

### 4.2.7.1.1 Uncoded and convolutionally encoded TrCHs

$$
a=2
$$

$$
\Delta \mathrm{N}_{\mathrm{i}}=\Delta \mathrm{N}_{\mathrm{i}, \mathrm{j}}
$$

$$
X_{i}=N_{i, j}
$$

$$
\mathrm{R}=\Delta \mathrm{N}_{\mathrm{ij}} \bmod \mathrm{~N}_{\mathrm{ij}}-- \text { note: in this context } \Delta \mathrm{N}_{\mathrm{ij}} \bmod \mathrm{~N}_{\mathrm{ij}} \text { is in the range of } 0 \text { to } \mathrm{N}_{\mathrm{ij}}-1 \text { i.e. }-1 \bmod 10=9 .
$$

$$
\text { if } \mathrm{R} \neq 0 \text { and } 2 \mathrm{R} \leq \mathrm{N}_{\mathrm{ij}}
$$

$$
\text { then } \mathrm{q}=\left\lceil\mathrm{N}_{\mathrm{ij}} / \mathrm{R}\right\rceil
$$

else

$$
\mathrm{q}=\left\lceil\mathrm{N}_{\mathrm{ij}} /\left(\mathrm{R}-\mathrm{N}_{\mathrm{ij}}\right)\right\rceil
$$

endif
-- note: $q$ is a signed quantity.

If $q$ is even

$$
\text { then } \mathrm{q}^{\prime}=\mathrm{q}+\operatorname{gcd}\left(|\mathrm{q}|, \mathrm{F}_{\mathrm{i}}\right) / \mathrm{F}_{\mathrm{i}}-- \text { where } \operatorname{gcd}\left(|\mathrm{q}|, \mathrm{F}_{\mathrm{i}}\right) \text { means greatest common divisor of }|\mathrm{q}| \text { and } \mathrm{F}_{\mathrm{i}}
$$

-- note that $\mathrm{q}^{\prime}$ is not an integer, but a multiple of $1 / 8$
else

$$
q^{\prime}=q
$$

endif

$$
\text { for } \mathrm{x}=0 \text { to } \mathrm{F}_{\mathrm{i}}-1
$$

$\left.\left.S\left(\mathrm{I}_{\mathrm{F}}\left(\| \mathrm{x}^{*} \mathrm{q}^{\prime}\right\rfloor \mid \bmod \mathrm{F}_{\mathrm{i}}\right)\right)=\left(\| \mathrm{x}^{*} \mathrm{q}^{\prime}\right\rfloor \mid \operatorname{div} \mathrm{F}_{\mathrm{i}}\right)$
end for
$\mathrm{e}_{\mathrm{ini}}=\left(\mathrm{a} \cdot \mathrm{S}\left(\mathrm{n}_{\mathrm{i}}\right) \cdot\left|\Delta \mathrm{N}_{\mathrm{i}}\right|+1\right) \bmod \left(\mathrm{a} \cdot \mathrm{X}_{\mathrm{i}}\right)$
$\mathrm{e}_{\text {plus }}=\mathrm{a} \cdot \mathrm{X}_{\mathrm{i}}$
$e_{\text {minus }}=a \cdot\left|\Delta N_{i}\right|$
puncturing for $\Delta N_{i}<0$, repetition otherwise.

### 4.2.7.1.2 Turbo encoded TrCHs

If repetition is to be performed on turbo encoded TrCHs , i.e. $\Delta N_{i, j}>0$, the parameters in section 4.2.7.1.1 are used.

If puncturing is to be performed, the parameters below shall be used. Index $b$ is used to indicate systematic $(b=1), 1^{\text {st }}$ parity $(b=2)$, and $2^{\text {nd }}$ parity bit $(b=3)$.

$$
\begin{aligned}
& \mathrm{a}=2 \text { when } b=2 \\
& \mathrm{a}=1 \text { when } b=3
\end{aligned}
$$

$$
\Delta N_{i}= \begin{cases}\left\lfloor\Delta N_{i, j} / 2\right\rfloor, & b=2 \\ \left\lceil\Delta N_{i, j} / 2\right\rceil, & b=3\end{cases}
$$

$$

For each radio frame, the rate-matching pattern is calculated with the algorithm in section 4.2.7.3, where:
$X_{i}$ is as above,
$e_{\text {ini }}=\left(a \cdot S\left(n_{i}\right) \cdot\left|\Delta N_{i}\right|+X_{i}\right) \bmod \left(a \cdot X_{i}\right)$, if $e_{i n i}=0$ then $e_{i n i}=a \cdot X_{i}$.
$\mathrm{e}_{\text {plus }}=\mathrm{a} \cdot \mathrm{X}_{\mathrm{i}}$
$\mathrm{e}_{\text {minus }}=\mathrm{a} \cdot\left|\Delta \mathrm{N}_{\mathrm{i}}\right|$

### 4.2.7.2 Bit separation and collection for rate matching

The systematic bits (excluding bits for trellis termination) of turbo encoded TrCHs shall not be punctured. The systematic bit, first parity bit, and second parity bit in the bit sequence input to the rate matching block are therefore separated from each other. Puncturing is only applied to the parity bits and systematic bits used for trellis termination.

The bit separation function is transparent for uncoded TrCHs , convolutionally encoded TrCHs , and for turbo encoded TrCHs with repetition. The bit separation and bit collection are illustrated in figures 4-5 and 4-6.

Figure 4-5: Puncturing of turbo encoded TrCHs

Figure 4-6: Rate matching for uncoded TrCHs, convolutionally encoded TrCHs, and for turbo encoded TrCHs with repetition.

The bit separation is dependent on the $1^{\text {st }}$ interleaving and offsets are used to define the separation for different TTIs. The offsets $\alpha_{b}$ for the systematic $(b=1)$ and parity bits $(b \in\{2,3\})$ are listed in table 4.2.7-1.

Table 4.2.7-1: TTI dependent offset needed for bit separation

| TTI (ms) | $\alpha_{1}$ | $\alpha_{2}$ | $\alpha_{3}$ |
| :---: | :---: | :---: | :---: |
| 10,40 | 0 | 1 | 2 |
| 20,80 | 0 | 2 | 1 |

The bit separation is different for different radio frames in the TTI. A second offset is therefore needed. The radio frame number for $\operatorname{TrCH} i$ is denoted by $n_{i}$. and the offset by $\beta_{n_{i}}$.

Table 4.2.7-2: Radio frame dependent offset needed for bit separation

| TTI (ms) | $\beta_{0}$ | $\beta_{1}$ | $\beta_{2}$ | $\beta_{3}$ | $\beta_{4}$ | $\beta_{5}$ | $\beta_{6}$ | $\beta_{7}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10 | 0 | NA | NA | NA | NA | NA | NA | NA |
| 20 | 0 | 1 | NA | NA | NA | NA | NA | NA |
| 40 | 0 | 1 | 2 | 0 | NA | NA | NA | NA |
| 80 | 0 | 1 | 2 | 0 | 1 | 2 | 0 | 1 |

### 4.2.7.2.1 Bit separation

The bits input to the rate matching are denoted by $e_{i 1}, e_{i 2}, e_{i 3}, \ldots, e_{i N_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $N_{i}$ is the number of bits input to the rate matching block. Note that the transport format combination number $j$ for simplicity has been left out in the bit numbering, i.e. $N_{i}=N_{i j}$. The bits after separation are denoted by $x_{b i 1}, x_{b i 2}, x_{b i 3}, \ldots, x_{b i X_{i}}$. For turbo encoded TrCHs with puncturing, $b$ indicates systematic, first parity, or second parity bit. For all other cases $b$ is defined to be 1. $X_{i}$ is the number of bits in each separated bit sequence. The relation between $e_{i k}$ and $x_{b i k}$ is given below.

For turbo encoded TrCH s with puncturing:
$x_{1, i, k}=e_{i, 3(k-1)+1+\left(\alpha_{1}+\beta_{n_{i}}\right) \bmod 3} \quad k=1,2,3, \ldots, X_{i} \quad X_{i}=\left\lfloor N_{i} / 3\right\rfloor$
$x_{1, i,\left\lfloor N_{i} / 3\right\rfloor+k}=e_{i, 3\left\lfloor N_{i} / 3\right\rfloor+k} \quad k=1, \ldots, N_{i} \bmod 3 \quad$ Note: When $\left(N_{i} \bmod 3\right)=0$ this row is not needed.

$$
\begin{array}{lll}
x_{2, i, k}=e_{i, 3(k-1)+1+\left(\alpha_{2}+\beta_{n_{i}}\right) \bmod 3} & k=1,2,3, \ldots, X_{i} & X_{i}=\left\lfloor N_{i} / 3\right\rfloor \\
\left.x_{3, i, k}=e_{i, 3(k-1)+1+\left(\alpha_{3}+\beta_{n}\right)}\right) \bmod 3 & k=1,2,3, \ldots, X_{i} & X_{i}=\left\lfloor N_{i} / 3\right\rfloor
\end{array}
$$

For uncoded TrCHs , convolutionally encoded TrCHs , and turbo encoded TrCHs with repetition:

$$
x_{1, i, k}=e_{i, k} \quad k=1,2,3, \ldots, X_{i} \quad X_{i}=N_{i}
$$

### 4.2.7.2.2 Bit collection

The bits $x_{b i k}$ are input to the rate matching algorithm described in section 4.2.7.3. The bits output from the rate matching algorithm are denoted $y_{b i 1}, y_{b i 2}, y_{b i 3}, \ldots, y_{b i Y_{i}}$.

Bit collection is the inverse function of the separation. The bits after collection are denoted by $z_{b i 1}, z_{b i 2}, z_{b i 3}, \ldots, z_{b i Y_{i}}$. After bit collection, the bits indicated as punctured are removed and the bits are then denoted by $f_{i 1}, f_{i 2}, f_{i 3}, \ldots, f_{i V_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $V_{i}=N_{i j}+\Delta N_{i j}$. The relations between $y_{b i k}, z_{b i k}$, and $f_{i k}$ are given below.

For turbo encoded TrCHs with puncturing ( $Y_{i}=X_{i}$ ):

$$
\begin{array}{ll}
z_{i, 3(k-1)+1+\left(\alpha_{1}+\beta_{n_{i}}\right) \bmod 3}=y_{1, i, k} & k=1,2,3, \ldots, Y_{I} \\
z_{i, 3\left\lfloor N_{i} / 3\right\rfloor+k}=y_{1, i,\left\lfloor N_{i} / 3\right\rfloor+k} & k=1, \ldots, N_{i} \bmod 3 \quad \text { Note: When }\left(N_{i} \bmod 3\right)=0 \text { this row is not needed. } \\
z_{i, 3(k-1)+1+\left(\alpha_{2}+\beta_{n_{i}}\right) \bmod 3}=y_{2, i, k} & k=1,2,3, \ldots, Y_{i} \\
z_{i, 3(k-1)+1+\left(\alpha_{3}+\beta_{n_{i}}\right) \bmod 3}=y_{3, i, k} & k=1,2,3, \ldots, Y_{i}
\end{array}
$$

After the bit collection, bits $z_{i, k}$ with value $\delta$, where $\delta \notin\{0,1\}$, are removed from the bit sequence. Bit $f_{i, 1}$ corresponds to the bit $z_{i, k}$ with smallest index $k$ after puncturing, bit $f_{i, 2}$ corresponds to the bit $z_{i, k}$ with second smallest index $k$ after puncturing, and so on.

For uncoded TrCHs , convolutionally encoded TrCHs , and turbo encoded TrCHs with repetition:

$$
z_{i, k}=y_{1, i, k} \quad k=1,2,3, \ldots, Y_{i}
$$

When repetition is used, $f_{i, k}=z_{i, k}$ and $Y_{i}=V_{i}$.
When puncturing is used, $Y_{i}=X_{i}$ and bits $z_{i, k}$ with value $\delta$, where $\delta \notin\{0,1\}$, are removed from the bit sequence. Bit $f_{i, 1}$ corresponds to the bit $z_{i, k}$ with smallest index $k$ after puncturing, bit $f_{i, 2}$ corresponds to the bit $z_{i, k}$ with second smallest index $k$ after puncturing, and so on.

### 4.2.7.3 Rate matching pattern determination

The bits input to the rate matching are denoted by $x_{i 1}, x_{i 2}, x_{i 3}, \ldots, x_{i X_{i}}$, where $i$ is the $\operatorname{TrCH}$ and $X_{\mathrm{i}}$ is the parameter given in section 4.2.7.1.1 and 4.2.7.1.2.The bits output from the rate matching are denoted by $f_{i 1}, f_{i 2}, f_{13}, \ldots, f_{i V_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $V_{i}=N+\Delta N$.

Note that the transport format combination number j for simplicity has been left out in the bit numbering.
The rate matching rule is as follows:
if puncturing is to be performed
$e=e_{\text {ini }} \quad--$ initial error between current and desired puncturing ratio

```
    m=1 -- index of current bit
    do while m <= Xi
        e=e- eminus -- update error
        if e<= 0 then -- check if bit number m should be punctured
            set bit \mp@subsup{x}{i,m}{}\mathrm{ to }\delta\mathrm{ where }\delta\not\in{0,1}
            e}=e+\mp@subsup{e}{\mathrm{ plus }}{}\quad-- update error
        end if
        m=m+1 -- next bit
    end do
else
    e}=\mp@subsup{e}{\mathrm{ ini }}{}\quad-- initial error between current and desired puncturing ratio
    m}=1\quad -- index of current bit
    do while m <= X 
        e=e- eminus -- update error
        do while e <= 0 -- check if bit number m should be repeated
            repeat bit }\mp@subsup{x}{i,m}{
            e}=e+\mp@subsup{e}{\mathrm{ plus }}{}\quad-- update error
        end do
        m=m + 1 -- next bit
    end do
end if
```

A repeated bit is placed directly after the original one.

### 4.2.8 $\quad \mathrm{TrCH}$ multiplexing

Every 10 ms , one radio frame from each TrCH is delivered to the TrCH multiplexing. These radio frames are serially multiplexed into a coded composite transport channel ( CCTrCH ).

The bits input to the $\operatorname{TrCH}$ multiplexing are denoted by $f_{i 1}, f_{i 2}, f_{i 3}, \ldots, f_{i V_{i}}$, where $i$ is the $\operatorname{TrCH}$ number and $V_{i}$ is the number of bits in the radio frame of $\operatorname{TrCH} i$. The number of TrCHs is denoted by $I$. The bits output from TrCH multiplexing are denoted by $s_{1}, s_{2}, s_{3}, \ldots, s_{S}$, where $S$ is the number of bits, i.e. $S=\sum_{i} V_{i}$. $\operatorname{The} \operatorname{TrCH}$ multiplexing is defined by the following relations:

$$
\begin{aligned}
& s_{k}=f_{1 k} \quad k=1,2, \ldots, V_{1} \\
& s_{k}=f_{2,\left(k-V_{1}\right)} \quad k=V_{1}+1, V_{1}+2, \ldots, V_{1}+V_{2} \\
& s_{k}=f_{3,\left(k-\left(V_{1}+V_{2}\right)\right)} \quad k=\left(V_{1}+V_{2}\right)+1,\left(V_{1}+V_{2}\right)+2, \ldots,\left(V_{1}+V_{2}\right)+V_{3}
\end{aligned}
$$

$$
s_{k}=f_{I,\left(k-\left(V_{1}+V_{2}+\ldots+V_{I-1}\right)\right)} \quad k=\left(V_{1}+V_{2}+\ldots+V_{I-1}\right)+1,\left(V_{1}+V_{2}+\ldots+V_{I-1}\right)+2, \ldots,\left(V_{1}+V_{2}+\ldots+V_{I-1}\right)+V_{I}
$$

### 4.2.9 Physical channel segmentation

When more than one PhCH is used, physical channel segmentation divides the bits among the different PhCHs. The bits input to the physical channel segmentation are denoted by $s_{1}, s_{2}, s_{3}, \ldots, s_{S}$, where S is the number of bits input to the physical channel segmentation block. The number of PhCHs is denoted by $P$.

The bits after physical channel segmentation are denoted $u_{p 1}, u_{p 2}, u_{p 3}, \ldots, u_{p U_{p}}$, where $p$ is PhCH number and $U_{p}$ is the in general variable number of bits in the respective radio frame for each PhCH . The relation between $\mathrm{s}_{k}$ and $u_{p k}$ is given below.

Bits on first PhCH after physical channel segmentation:

$$
u_{1 k}=s_{k} \quad k=1,2, \ldots, U_{I}
$$

Bits on second PhCH after physical channel segmentation:

$$
u_{2 k}=s_{\left(k+U_{1}\right)} \quad k=1,2, \ldots, U_{2}
$$

Bits on the $P^{\text {th }} \mathrm{PhCH}$ after physical channel segmentation:

$$
u_{P k}=s_{\left(k+U_{1}+\ldots+U_{P-1}\right)} \quad k=1,2, \ldots, U_{P}
$$

### 4.2.10 2nd interleaving

The 2nd interleaving can be applied jointly to all data bits transmitted during one frame, or separately within each timeslot, on which the CCTrCH is mapped. The selection of the 2 nd interleaving scheme is controlled by higher layer.

### 4.2.10.1 Frame related 2nd interleaving

In case of frame related interleaving, the bits input to the $2^{\text {nd }}$ interleaver are denoted $x_{1}, x_{2}, x_{3}, \ldots, x_{U}$, where $U$ is the total number of bits after TrCH multiplexing transmitted during the respective radio frame.

The relation between $x_{k}$ and the bits $u_{p k}$ in the respective physical channels is given below:

$$
\begin{aligned}
& x_{k}=u_{1 k} k=1,2, \ldots, U_{1} \\
& x_{\left(k+U_{1}\right)}=u_{2 k} \mathrm{k}=1,2, \ldots, \mathrm{U}_{2} \\
& \ldots \\
& x_{\left(k+U_{1}+\ldots+U_{P-1}\right)}=u_{P k} \quad \mathrm{k}=1,2, \ldots, \mathrm{U}_{\mathrm{P}}
\end{aligned}
$$

The following steps have to be performed once for each CCTrCH :
(1) Set the number of columns $\mathrm{C}_{2}=30$. The columns are numbered $0,1,2, \ldots, \mathrm{C}_{2}-1$ from left to right.
(2) Determine the number of rows $R_{2}$ by finding minimum integer $R_{2}$ such that $\mathrm{U} \leq \mathrm{R}_{2} \mathrm{C}_{2}$.
(3) The bits input to the $2^{\text {nd }}$ interleaving are written into the $\mathrm{R}_{2} \times \mathrm{C}_{2}$ rectangular matrix row by row.

$$
\left[\begin{array}{ccccc}
x_{1} & x_{2} & x_{3} & \ldots & x_{30} \\
x_{31} & x_{32} & x_{33} & \ldots & x_{60} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
x_{\left(R_{2}-1\right) 30+1} & x_{\left(R_{2}-1\right) 30+2} & x_{\left(R_{2}-1\right) 30+3} & \ldots x_{R_{2} \cdot 30}
\end{array}\right]
$$

(4) Perform the inter-column permutation based on the pattern $\left\{\mathrm{P}_{2}(\mathrm{j})\right\}\left(\mathrm{j}=0,1, \ldots, \mathrm{C}_{2}-1\right)$ that is shown in table 4.2.9-1, where $P_{2}(j)$ is the original column position of the $j$-th permuted column. After permutation of the columns, the bits are denoted by $\mathrm{y}_{\mathrm{k}}$.

$$
\left[\begin{array}{cccl}
y_{1} & y_{R_{2}+1} & y_{2 R_{2}+1} & \ldots y_{29 R_{2}+1} \\
y_{2} & y_{R_{2}+2} & y_{2 R_{2}+2} & \ldots y_{29 R_{2}+2} \\
\vdots & \vdots & \vdots & \ldots \\
\vdots \\
y_{R_{2}} & y_{2 R_{2}} & y_{3 R_{2}} & \ldots y_{30 R_{2}}
\end{array}\right]
$$

(5) The output of the $2^{\text {nd }}$ interleaving is the bit sequence read out column by column from the inter-column permuted $R_{2} \times C_{2}$ matrix. The output is pruned by deleting bits that were not present in the input bit sequence, i.e. bits $y_{k}$ that corresponds to bits $\mathrm{X}_{\mathrm{k}}$ with $\mathrm{k}>\mathrm{U}$ are removed from the output. The bits after $2^{\text {nd }}$ interleaving are denoted by $v_{1}, v_{2}, \ldots, v_{U}$, where $\mathrm{V}_{1}$ corresponds to the bit $\mathrm{y}_{\mathrm{k}}$ with smallest index k after pruning, $\mathrm{v}_{2}$ to the bit $\mathrm{y}_{\mathrm{k}}$ with second smallest index k after pruning, and so on.

### 4.2.10.2 Timeslot related $2^{\text {nd }}$ interleaving

In case of timeslot related $2^{\text {nd }}$ interleaving, the bits input to the $2^{\text {nd }}$ interleaver are denoted $x_{t 1}, x_{t 2}, x_{t 3}, \ldots, x_{t U_{t}}$, where $t$ refers to a certain timeslot, and $U_{t}$ is the number of bits transmitted in this timeslot during the respective radio frame.

In each timeslot $t$ the relation between $X_{t k}$ and $u_{p k}$ is given below with $\mathrm{P}_{\mathrm{t}}$ refering to the number of physical channels within the respective timeslot:

$$
\begin{aligned}
& x_{t k}=u_{1 k} k=1,2, \ldots, U_{1} \\
& x_{t\left(k+U_{1}\right)}=u_{2 k} \quad k=1,2, \ldots, U_{2} \\
& \ldots \\
& x_{t\left(k+U_{1}+\ldots+U_{P_{t}-1}\right)}=u_{P_{t} k} \quad k=1,2, \ldots, U_{P_{t}}
\end{aligned}
$$

The following steps have to be performed for each timeslot $t$, on which the respective CCTrCH is mapped:
(1) Set the number of columns $C_{2}=30$. The columns are numbered $0,1,2, \ldots, C_{2}-1$ from left to right.
(2) Determine the number of rows $R_{2}$ by finding minimum integer $R_{2}$ such that $U_{t} \leq R_{2} C_{2}$.
(3) The bits input to the $2^{\text {nd }}$ interleaving are written into the $R_{2} \times C_{2}$ rectangular matrix row by row.

$$
\left[\begin{array}{ccccc}
x_{t 1} & x_{t 2} & x_{t 3} & \ldots & x_{t 30} \\
x_{t 31} & x_{t 32} & x_{t 33} & \ldots & x_{t 60} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
x_{t,\left(\left(R_{2}-1\right) 30+1\right)} & x_{t,\left(\left(R_{2}-1\right) 30+2\right)} & x_{t,\left(\left(R_{2}-1\right) 30+3\right)} & \ldots x_{t,\left(R_{2} 30\right)}
\end{array}\right]
$$

(4) Perform the inter-column permutation based on the pattern $\left\{P_{2}(j)\right\}\left(j=0,1, \ldots, C_{2}-1\right)$ that is shown in table 4.2.9-1, where $P_{2}(j)$ is the original column position of the $j$-th permuted column. After permutation of the columns, the bits are denoted by $y_{t k}$.

$$
\left[\begin{array}{cccl}
y_{t 1} & y_{t,\left(R_{2}+1\right)} & y_{t,\left(2 R_{2}+1\right)} & \ldots y_{t,\left(29 R_{2}+1\right)} \\
y_{t 2} & y_{t,\left(R_{2}+2\right)} & y_{t,\left(2 R_{2}+2\right)} & \ldots y_{t,\left(29 R_{2}+2\right)} \\
\vdots & \vdots & \vdots & \ldots \\
\vdots \\
y_{t R_{2}} & y_{t,\left(2 R_{2}\right)} & y_{t,\left(3 R_{2}\right)} & \ldots y_{t,\left(30 R_{2}\right)}
\end{array}\right]
$$

(5) The output of the $2^{\text {nd }}$ interleaving is the bit sequence read out column by column from the inter-column permuted $R_{2} \times C_{2}$ matrix. The output is pruned by deleting bits that were not present in the input bit sequence, i.e. bits $y_{t k}$ that corresponds to bits $x_{t k}$ with $k>U_{t}$ are removed from the output. The bits after $2^{\text {nd }}$ interleaving are denoted by $v_{t 1}, v_{t 2}, \ldots, v_{t U_{t}}$, where $v_{t 1}$ corresponds to the bit $y_{t k}$ with smallest index $k$ after pruning, $v_{t 2}$ to the bit $y_{t k}$ with second smallest index $k$ after pruning, and so on.

## Table 4.2.10-1

| Column number $\mathbf{C}_{2}$ | Inter-column permutation pattern |
| :---: | :---: |
| 30 | $\{0,20,10,5,15,25,3,13,23,8,18,28,1,11,21$, |
|  | $6,16,26,4,14,24,19,9,29,12,2,7,22,27,17\}$ |

### 4.2.11 Physical channel mapping

The PhCH for both uplink and downlink is defined in [6]. The bits after physical channel mapping are denoted by $w_{p 1}, w_{p 2}, \ldots, w_{p U_{p}}$, where $p$ is the PhCH number and $U_{p}$ is the number of bits in one radio frame for the respective PhCH . The bits $\mathrm{W}_{p k}$ are mapped to the PhCHs so that the bits for each PhCH are transmitted over the air in ascending order with respect to $k$. The mapping scheme depends on the applied $2^{\text {nd }}$ interleaving scheme.

### 4.2.11.1 Mapping scheme after frame related $2^{\text {nd }}$ interleaving

### 4.2.11.1.1 Mapping scheme after frame related 2nd interleaving in uplink

In uplink there are at most two codes allocated ( $\mathrm{P} \leq 2$ ). If there is only one code, the same mapping as for downlink is applied, see section 6.2.11.1.2. Denote SF1 and SF2 the spreading factors used for code 1 and 2, respectively. Then denote the inverse relation of the spreading factors s1: $\mathrm{s} 2=\mathrm{SF} 2$ : SF1, where the smallest possible integers are used for s1 and s2.

The following mapping rule is applied:
Bits are mapped on the first PhCH (in forward order) if $(k-1) \bmod (s 1+s 2)=0, \ldots, s 1-1$ :

$$
w_{1,(k \operatorname{div}(s 1+s 2)) \cdot s 1+k \bmod (s 1+s 2)}=v_{k}
$$

else bits are mapped on the second PhCH (in reverse order):

$$
w_{2, U_{2}-(k d i v(s 1+s 2)): s 2+k \bmod (s 1+s 2)-s 1}=v_{k}
$$

This formula is applied starting with $\mathrm{k}=1$ and increasing k until one of the PhCH is completely filled. From then on, the remaining bits are mapped on the PhCH which has not been filled in the same order (forward or reverse depending on the PhCH ) as used previously on that PhCH .

### 4.2.11.1.2 Mapping scheme after frame related 2nd interleaving in downlink

The mapping is equivalent to block interleaving, writing in colomns, but a PhCH with an odd number is filled in forward order, were as a PhCH with an even number is filled in reverse order.

The following mapping rule is applied:
Bits are mapped on an odd numbered PhCH (in forward order) according to the following rule, if $(\mathrm{k} \bmod \mathrm{P})+1$ is odd:

$$
w_{k \bmod P+1, k \operatorname{div} P}=v_{k}
$$

Bits are mapped on an even numbered PhCH (in reverse order) according to the following rule, if $(\mathrm{k} \bmod \mathrm{P})+1$ is even:

```
\(w_{k \bmod P+1, U_{P}-1-k \operatorname{div} P}=v_{k}\)
```

This formula is applied starting with $\mathrm{k}=1$ and increasing k until all the PhCHs which carry TFCI are completely filled. From then on, the remaining bits are mapped on the remaining PhCHs in the same order (forward or reverse depending on the PhCH ) as previously on these PhCHs .

### 4.2.11.2 Mapping scheme after timeslot related $2^{\text {nd }}$ interleaving

For each timeslot only those physical channels with $p=1,2, \ldots, P_{t}$ are considered respectively, which are transmitted in that timeslot, and the following mapping scheme is applied:

### 6.2.11.2.1 Mapping scheme after timeslot related 2nd interleaving in uplink

In uplink there are at most two codes allocated ( $\mathrm{P} \leq 2$ ). If there is only one code, the same mapping as for downlink is applied, see section 6.2.11.1.2 Denote SF1 and SF2 the spreading factors used for code 1 and 2, respectively. Then denote the inverse relation of the spreading factors $\mathrm{s} 1: \mathrm{s} 2=\mathrm{SF} 2$ : SF 1 , where the smallest possible integers are used for s1 and s2.

The following mapping rule is applied:
Bits are mapped on the first PhCH (in forward order) if $(k-1) \bmod (s 1+s 2)=0, \ldots, s 1-1$ :
$w_{1,(k d i v(s 1+s 2)) \cdot s 1+k \bmod (s 1+s 2)}=v_{t k}$
else bits are mapped on the second PhCH (in reverse order):

$$
w_{2, U_{2}-(k d i v(s 1+s 2)): s 2+k \bmod (s 1+s 2)-s 1}=v_{t k}
$$

This formula is applied starting with $\mathrm{k}=1$ and increasing k until one of the PhCH is completely filled. From then on, the remaining bits are mapped on the PhCH which has not been filled in the same order (forward or reverse depending on the PhCH ) as used previously on that PhCH .

### 6.2.11.2.2 Mapping scheme after timeslot related 2nd interleaving in downlink

The mapping is equivalent to block interleaving, writing in colomns, but a PhCH with an odd number is filled in forward order, were as a PhCH with an even number is filled in reverse order.

The following mapping rule is applied:
Bits are mapped on an odd numbered PhCH (in forward order) according to the following rule, if $\left(\mathrm{k} \bmod \mathrm{P}_{\mathrm{t}}\right)+1$ is odd:

$$
w_{k \bmod P_{t}+1, k d i v P_{t}}=v_{t k}
$$

Bits are mapped on an even numbered PhCH (in reverse order) according to the following rule, if $\left(\mathrm{k} \mathrm{mod} \mathrm{P}_{\mathrm{t}}\right)+1$ is even:

$$
w_{k \bmod P_{t}+1, U_{P_{t}}-1-k \operatorname{div} P_{t}}=v_{t k}
$$

This formula is applied starting with $\mathrm{k}=1$ and increasing k until all the PhCHs which carry TFCI are completely filled. From then on, the remaining bits are mapped on the remaining PhCHs in the same order (forward or reverse depending on the PhCH ) as previously on these PhCHs .

### 4.2.12 Multiplexing of different transport channels onto one CCTrCH, and mapping of one CCTrCH onto physical channels

Different transport channels can be encoded and multiplexed together into one Coded Composite Transport Channel $(\mathrm{CCTrCH})$. The following rules shall apply to the different transport channels which are part of the same CCTrCH :

1) Transport channels multiplexed into one CCTrCh should have co-ordinated timings in the sense that transport blocks arriving from higher layers on different transport channels of potentially different transmission time intervals shall have aligned transmission time instants as shown in figure 4-6.
2) Different CCTrCHs cannot be mapped onto the same physical channel.
3) One CCTrCH shall be mapped onto one or several physical channels.

Figure 4-6: Possible transmission time instants regarding $\mathbf{C C T r C H}$
4) Dedicated Transport channels and common transport channels cannot be multiplexed into the same CCTrCH .
5) For the common transport channels, only the FACH and PCH may belong to the same CCTrCH .
6) Each CCTrCH carrying a BCH shall carry only one BCH and shall not carry any other Transport Channel.
7) Each CCTrCH carrying a RACH shall carry only one RACH and shall not carry any other Transport Channel.

Hence, there are two types of CCTrCH
CCTrCH of dedicated type, corresponding to the result of coding and multiplexing of one or several DCH.
CCTrCH of common type, corresponding to the result of the coding and multiplexing of a common channel, i.e. RACH and USCH in the uplink and DSCH, BCH, FACH or PCH in the downlink, respectively.

Transmission of TFCI is possible for CCTrCH containing Transport Channels of:

- Dedicated type
- USCH type
- DSCH type
- FACH and/or PCH type

### 4.2.12.1 Allowed CCTrCH combinations for one UE

### 4.2.12.1.1 Allowed CCTrCH combinations on the uplink

The following CCTrCH combinations for one UE are allowed, also simultaneously:

1) several CCTrCH of dedicated type
2) several CCTrCH of common type

### 4.2.12.1.2 Allowed CCTrCH combinations on the downlink

The following CCTrCH combinations for one UE are allowed, also simultaneously:
3) several CCTrCH of dedicated type
4) several CCTrCH of common type

### 4.2.13 Transport format detection

Transport format detection can be performed both with and without Transport Format Combination Indicator (TFCI). If a TFCI is transmitted, the receiver detects the transport format combination from the TFCI. When no TFCI is transmitted, so called blind transport format detection may be used, i.e. the receiver side uses the possible transport format combinations as a priori information.

### 4.2.13.1 Blind transport format detection

Blind transport format detection may be performed in the receiver by trying all possible combinations of the transport format.

### 4.2.13.2 Explicit transport format detection based on TFCI

### 4.2.13.2.1 Transport Format Combination Indicator (TFCI)

The Transport Format Combination Indicator (TFCI) informs the receiver of the transport format combination of the CCTrCHs . As soon as the TFCI is detected, the transport format combination, and hence the individual transport channels' transport formats are known, and decoding of the transport channels can be performed.

### 4.3 Coding for layer 1 control

### 4.3.1 Coding of transport format combination indicator (TFCI)

Encoding of the TFCI bits depends on the number of them. If there are 6-10 bits of TFCI the channel encoding is done as described in section 4.3.1.1. Also specific coding of less than 6 bits is possible as explained in section 4.3.1.2.

### 4.3.1.1 Coding of long TFCI lengths

The TFCI bits are encoded using a $(32,10)$ sub-code of the second order Reed-Muller code. The coding procedure is as shown in figure 4.3.3.1-1.

Figure 4.3.3.1-1: Channel coding of TFCI bits
TFCI is encoded by the $(32,10)$ sub-code of second order Reed-Muller code. The code words of the $(32,10)$ sub-code of second order Reed-Muller code are linear combination of some among 10 basis sequences. The basis sequences are as follows in table 4.3.1-1.

Table 4.3.1-1: Basis sequences for $(32,10)$ TFCI code

| $\mathbf{I}$ | $\mathrm{M}_{\mathrm{i}, 0}$ | $\mathrm{M}_{\mathrm{i}, 1}$ | $\mathrm{M}_{\mathrm{i}, 2}$ | $\mathrm{M}_{\mathrm{i}, 3}$ | $\mathrm{M}_{\mathrm{i}, 4}$ | $\mathrm{M}_{\mathrm{i}, 5}$ | $\mathrm{M}_{\mathrm{i}, 6}$ | $\mathrm{M}_{\mathrm{i}, 7}$ | $\mathrm{M}_{\mathrm{i}, 8}$ | $\mathrm{M}_{\mathrm{i}, 9}$ |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |
| 2 | 1 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |
| 3 | 1 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 1 |
| 4 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 1 |
| 5 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 |
| 6 | 1 | 1 | 1 | 1 | 0 | 0 | 0 | 1 | 0 | 0 |
| 7 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 1 | 0 |
| 8 | 1 | 1 | 0 | 0 | 1 | 0 | 1 | 1 | 1 | 0 |
| 9 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 1 |
| 10 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 1 | 1 |
| 11 | 1 | 0 | 0 | 1 | 1 | 0 | 0 | 1 | 1 | 0 |
| 12 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 1 | 0 | 1 |
| 13 | 1 | 0 | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 |
| 14 | 1 | 1 | 1 | 1 | 1 | 0 | 1 | 1 | 1 | 1 |
| 15 | 1 | 1 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 |
| 16 | 1 | 0 | 1 | 0 | 0 | 1 | 1 | 1 | 0 | 1 |
| 17 | 1 | 1 | 1 | 0 | 0 | 1 | 1 | 0 | 1 | 0 |
| 18 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 1 | 1 | 1 |
| 19 | 1 | 1 | 0 | 1 | 0 | 1 | 0 | 1 | 0 | 1 |
| 20 | 1 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |
| 21 | 1 | 1 | 1 | 1 | 0 | 1 | 0 | 1 | 1 | 1 |
| 22 | 1 | 0 | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 |
| 23 | 1 | 1 | 0 | 0 | 1 | 1 | 1 | 1 | 0 | 1 |
| 24 | 1 | 0 | 1 | 0 | 1 | 1 | 1 | 0 | 1 | 0 |
| 25 | 1 | 1 | 1 | 0 | 1 | 1 | 1 | 0 | 0 | 1 |
| 26 | 1 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 0 |
| 27 | 1 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 0 | 0 |
| 28 | 1 | 0 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 0 |
| 29 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| 30 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |
| 31 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 |
|  |  |  |  |  |  |  |  |  |  |  |

For TFCI bits $a_{0}, a_{1}, a_{2}, a_{3}, a_{4}, a_{5}, a_{6}, a_{7}, a_{8}, a_{9}\left(a_{0}\right.$ is LSB and $a_{9}$ is MSB $)$, the output code word bits $b_{i}$ are given by:
$b_{i}=\sum_{n=0}^{9}\left(a_{n} \times M_{i, n}\right) \bmod 2$
where $\mathrm{i}=0 \ldots 31 . \mathrm{N}_{\text {TFCI }}=32$.

### 4.3.1.2 Coding of short TFCI lengths

### 4.3.1.2.1 Coding very short TFCls by repetition

If the number of TFCI bits is 1 or 2 , then repetition will be used for coding. In this case each bit is repeated to a total of 4 times giving 4-bit transmission ( $\mathrm{N}_{\text {TFCI }}=4$ ) for a single TFCI bit and 8-bit transmission $\left(\mathrm{N}_{\mathrm{TFCI}}=8\right)$ for 2 TFCI bits. In the case of two TFCI bits denoted $b_{0}$ and $b_{1}$ the TFCI word shall be $\left\{b_{0}, b_{1}, b_{0}, b_{1}, b_{0}, b_{1}, b_{0}, b_{1}\right\}$.

### 4.3.1.2.2 Coding short TFCls using bi-orthogonal codes

If the number of TFCI bits is in the range 3 to 5 the TFCI bits are encoded using a $(16,5)$ bi-orthogonal (or first order Reed-Muller) code. The coding procedure is as shown in figure 4-8.

Figure 4-8: Channel coding of short length TFCI bits
The code words of the $(16,5)$ bi-orthogonal code are linear combinations of 5 basis sequences as defined in table 4.3.1-2 below.

Table 4.3.1-2: Basis sequences for $(16,5) \mathrm{TFCl}$ code

| i | $\mathrm{M}_{\mathrm{i}, 0}$ | $\mathrm{M}_{\mathrm{i}, 1}$ | $\mathrm{M}_{\mathrm{i}, 2}$ | $\mathrm{M}_{\mathrm{i}, 3}$ | $\mathrm{M}_{\mathrm{i}, 4}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 1 | 1 | 0 | 0 | 0 |
| 1 | 1 | 0 | 1 | 0 | 0 |
| 2 | 1 | 1 | 1 | 0 | 0 |
| 3 | 1 | 0 | 0 | 1 | 0 |
| 4 | 1 | 1 | 0 | 1 | 0 |
| 5 | 1 | 0 | 1 | 1 | 0 |
| 6 | 1 | 1 | 1 | 1 | 0 |
| 7 | 1 | 0 | 0 | 0 | 1 |
| 8 | 1 | 1 | 0 | 0 | 1 |
| 9 | 1 | 0 | 1 | 0 | 1 |
| 10 | 1 | 1 | 1 | 0 | 1 |
| 11 | 1 | 0 | 0 | 1 | 1 |
| 12 | 1 | 1 | 0 | 1 | 1 |
| 13 | 1 | 0 | 1 | 1 | 1 |
| 14 | 1 | 1 | 1 | 1 | 1 |
| 15 | 1 | 0 | 0 | 0 | 0 |

For TFCI information bits $a_{0}, a_{1}, a_{2}, a_{3}, a_{4}\left(a_{0}\right.$ is LSB and $a_{4}$ is MSB $)$, the $)$, the output code word bits $b_{j}$ are given by:
$b_{i}=\sum_{n=0}^{4}\left(a_{n} \times M_{i, n}\right) \bmod 2$
where $\mathrm{i}=0 \ldots 15 . \mathrm{N}_{\mathrm{TFCI}}=16$.

### 4.3.1.3 Mapping of TFCI word

The mapping of the TFCI word to the TFCI bit positions in a timeslot shall be as follows.
Denote the number of bits in the TFCI word by $\mathrm{N}_{\mathrm{TFCI}}$, denote the code word bits by $\mathrm{b}_{\mathrm{k}}$ where $\mathrm{k}=0 \ldots \mathrm{~N}_{\mathrm{TFCI}}-1$.

Figure 4-9: Mapping of TFCI word bits to timeslot
The locations of the first and second parts of the TFCI in the timeslot is defined in [7].
If the shortest transmission time interval of any constituent $\operatorname{TrCH}$ is at least 20 ms the successive TFCI words in the frames in the TTI shall be identical. If TFCI is transmitted on multiple timeslots in a frame each timeslot shall have the same TFCI word.

### 4.3.2 Coding of Paging Indicator (PI)

The PI is an identifier to instruct the UE whether there is a paging message for the groups of mobiles that are associated to the PI. The length $L_{P I}$ of the $P I$ is $L_{P I}=2, L_{P I}=4$ or $L_{P I}=8$ symbols. The coding of the PI is shown in table 4.3.3-1.

Table 4.3.3-1: Coding of the PI

| Bits | PI |  |
| :--- | :--- | :--- |
| All ' 0 ' | Not set | There is no necessity to receive PCH |
| All ' 1 ' | Set | There is necessity to receive PCH- |

### 4.3.3 Coding of Transmit Power Control (TPC)

The TPC command is an identifier sent in uplink transmission only, to instruct the NodeB whether Tx power has to be increased or decreased. The length of the TPC command is one symbol. The coding of the TPC command is shown in table 4.3.3-1.

Table 4.3.4-1: Coding of the TPC

| TPC | TPC Bits |  |
| :--- | :--- | :--- |
| 'Down' | 00 | Decrease Tx Power |
| 'Up' | 11 | Increase Tx Power |
