History ........................................................................................................................................... 34
Foreword

This Technical Specification (TS) has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

x  the first digit:

   1  presented to TSG for information;
   2  presented to TSG for approval;
   3  or greater indicates TSG approved document under change control.

y  the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.

z  the third digit is incremented when editorial only changes have been incorporated in the document.
1 Scope

The present document shall provide a description of the UTRAN Iur and Iub interfaces user plane protocols for Dedicated Transport Channel data streams as agreed within the TSG-RAN working group 3.

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document in the same Release as the present document.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

Transport Bearer: service provided by the transport layer and used by frame protocol for the delivery of FP PDU
3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

- BER: Bit Error Rate
- CFN: Connection Frame Number
- CRC: Cyclic Redundancy Checksum
- CRCI: CRC Indicator
- DCH: Dedicated Transport Channel
- DL: Downlink
- DSCH: Downlink Shared Channel
- DTX: Discontinuous Transmission
- FP: Frame Protocol
- FT: Frame Type
- LTOA: Latest Time of Arrival
- PC: Power Control
- QE: Quality Estimate
- SIR: Signal-to-Interference Ratio
- TB: Transport Block
- TBS: Transport Block Set
- TFI: Transport Format Indicator
- TFCl: Transport Format Combination Indicator
- ToA: Time of Arrival
- ToAWE: Time of Arrival Window Endpoint
- ToAWS: Time of Arrival Window Startpoint
- TTI: Transmission Time Interval
- UL: Uplink

3.3 Specification Notations

For the purposes of the present document, the following notations apply:

- [FDD] This tagging of a word indicates that the word preceding the tag "[FDD]" applies only to FDD. This tagging of a heading indicates that the heading preceding the tag "[FDD]" and the section following the heading applies only to FDD.
- [TDD] This tagging of a word indicates that the word preceding the tag "[TDD]" applies only to TDD. This tagging of a heading indicates that the heading preceding the tag "[TDD]" and the section following the heading applies only to TDD.
- [FDD - …] This tagging indicates that the enclosed text following the "[FDD - " applies only to FDD. Multiple sequential paragraphs applying only to FDD are enclosed separately to enable insertion of TDD specific (or common) paragraphs between the FDD specific paragraphs.
- [TDD - …] This tagging indicates that the enclosed text following the "[TDD - " applies only to TDD. Multiple sequential paragraphs applying only to TDD are enclosed separately to enable insertion of FDD specific (or common) paragraphs between the TDD specific paragraphs.

Procedure When referring to a procedure in the specification, the Procedure Name is written with the first letters in each word in upper case characters followed by the word "procedure", e.g. Timing Adjustment procedure.

Frame When referring to a control or data frame in the specification, the CONTROL/DATA FRAME NAME is written with all letters in upper case characters followed by the words "control/data frame", e.g. DL SYNCHRONISATION control frame.

IE When referring to an information element (IE) in the specification, the Information Element Name is written with the first letters in each word in upper case characters and all letters in Italic font followed by the abbreviation "IE", e.g. Connection Frame Number IE.

Value of an IE When referring to the value of an information element (IE) in the specification, the "Value" is written as it is specified in subclause 6.2.4 or 6.3.3 enclosed by quotation marks, e.g. "0" or "255".
4 General aspects

The specification of Iub DCH data streams is also valid for Iur DCH data streams.

The complete configuration of the transport channel is selected by the SRNC and signalled to the Node B via the Iub and Iur control plane protocols.

The parameters of a transport channel are described in [1]. Transport channels are multiplexed on the downlink by the Node B on radio physical channels, and de-multiplexed on the uplink from radio physical channels to transport channels.

In Iur interface, every set of coordinated transport channels related to one UE context that is communicated over a set of cells that are macro-diversity combined within Node B or DRNC, is carried on one transport bearer. This means that there are as many transport bearers as set of coordinated transport channels and Iur DCH data ports for that communication.

In Iub interface, every set of coordinated transport channels related to one UE context that is communicated over a set of cells that are macro-diversity combined within Node B is carried on one transport bearer. This means that there are as many transport bearers as set of coordinated transport channels and Iub DCH data ports for that communication.

Bi-directional transport bearers are used.

4.1 DCH FP services

DCH frame protocol provides the following services:

- Transport of TBS across Iub and Iur interface.
- Transport of outer loop power control information between the SRNC and the Node B.
- Support of transport channel synchronisation mechanism.
- Support of node synchronization mechanism.
- Transfer of DSCH TFCI from SRNC to Node B.
- [TDD - Transfer of Rx timing deviation from the Node B to the SRNC.]
- Transfer of radio interface parameters from the SRNC to the Node B.

4.2 Services expected from the Data Transport Network layer

Following service is required from the transport layer:

- Delivery of FP PDU.

In sequence delivery is not required. However, frequent out-of-sequence delivery may impact the performance and should be avoided.

4.3 Protocol Version

This revision of the specification specifies version 1 of the protocol.
5 DCH Frame Protocol procedures

5.1 Data Transfer

5.1.0 General

When there is some data to be transmitted, DCH data frames are transferred every transmission time interval from the SRNC to the Node B for downlink transfer, and from Node B to the SRNC for uplink transfer.

An optional error detection mechanism may be used to protect the data transfer if needed. At the transport channel setup it shall be specified if the error detection on the user data is used.

5.1.1 Uplink

Two modes can be used for the UL transmission: normal mode and silent mode. The mode is selected by the SRNC when the transport bearer is setup and signalled to the Node B with the relevant control plane procedure.

- In normal mode, the Node B shall always send an UL DATA FRAME to the RNC for all the DCHs in a set of coordinated DCHs regardless of the number of Transport Blocks of the DCHs.
- In silent mode and in case only one transport channel is transported on a transport bearer, the Node B shall not send an UL DATA FRAME to the RNC when it has received a TFI indicating “number of TB equal to 0” for the transport channel during a TTI.
- In silent mode and in case of coordinated DCHs, when the Node B receives a TFI indicating “number of TB equal to 0” for all the DCHs in a set of coordinated DCHs, the Node B shall not send an UL DATA FRAME to the RNC for this set of coordinated DCHs.

For any TTI in which the Node B Layer 1 generated at least one CPHY-Out-of-Sync-IND primitive, the Node B is not required to send an UL DATA FRAME to the SRNC.

When Node B receives an invalid TFCI, no UL DATA FRAME shall be sent to the SRNC.

5.1.2 Downlink

The Node B shall only consider a transport bearer synchronised after it has received at least one DL DATA FRAME on this transport bearer before LTOA [5].
The Node B shall consider the DL user plane of a certain RL synchronised once all transport bearers established to carry DCH DL DATA FRAMEs for this RL are considered as synchronised. Once synchronised, the Node B shall assume the DL user plane for this RL stays synchronised as long as the RL exists, even if transport bearers are added (see subclause 5.10.2), replaced (see subclause 5.10.1), or removed. When a RL established through the Radio Link Addition procedure [4] [6] is combined with a RL whose DL user plane is considered as synchronised, the Node B shall consider the DL user plane of this newly established RL as synchronised.

[FDD - The Node B shall transmit on the DL DPDCH(s) of a certain RL only when the DL user plane of this RL is considered synchronised.]

[TDD – The Node B shall transmit special bursts on the DL DPCH as per [11], until the DL user plane is considered synchronised.]

When the DL user plane is considered synchronised and the Node B does not receive a valid DL DATA FRAME in a TTI, it assumes that there is no data to be transmitted in that TTI for this transport channel, and shall act as one of the following cases:

- [TDD – If the Node B receives no valid DL DATA FRAMEs for any transport channel assigned to a UE it shall assume DTX and transmit special bursts as per [11]].

- If the Node B is aware of a TFI value corresponding to zero bits for this transport channel, this TFI is assumed. If the TFS contains both a TFI corresponding to "TB length equal to 0 bits" and a TFI corresponding to "number of TB equal to 0", the Node B shall assume the TFI corresponding to "number of TB equal to 0". When combining the TFIs of the different transport channels, a valid TFCI might result and in this case data shall be transmitted on Uu.

- If the Node B is not aware of a TFI value corresponding to zero bits for this transport channel or if combining the TFI corresponding to zero bits with other TFIs, results in an unknown TFI combination, the handling as described in the following paragraph shall be applied.

At each radio frame, the Node B shall build the TFCI value of each CCTrCH, according to the TFI of the DCH data frames multiplexed on this CCTrCH and scheduled for that frame. [FDD - In case the Node B receives an unknown combination of TFIs from the DL DATA FRAMEs, it shall transmit only the DPCCH without TFCI bits.] [TDD - In case the Node B receives an unknown combination of DCH DL DATA FRAMEs, it shall apply DTX, i.e. suspend transmission on the corresponding DPCHs.]

## 5.2 Timing Adjustment

The Timing Adjustment procedure is used to keep the synchronisation of the DCH data stream in DL direction, i.e to ensure that the Node B receives the DL frames in an appropriate time for the transmission of the data in the air interface.

SRNC always includes the Connection Frame Number (CFN) to all DCH DL DATA FRAMEs. The same applies to the DSCH TFCI SIGNALLING control frame.

If a DL DATA FRAME or a DSCH TFCI SIGNALLING control frame arrives outside the arrival window defined in the Node B, the Node B shall send a TIMING ADJUSTMENT control frame, containing the measured ToA and the CFN value of the received DL DATA FRAME.

![Figure 3: Timing Adjustment procedure](image)

The arrival window and the time of arrival are defined as follows:
**Time of Arrival Window Endpoint (ToAWE):** ToAWE represents the time point by which the DL data shall arrive to the Node B from Iub. The ToAWE is defined as the amount of milliseconds before the last time point from which a timely DL transmission for the identified CFN would still be possible taking into account the Node B internal delays. ToAWE is set via control plane. If data does not arrive before ToAWE a TIMING ADJUSTMENT control frame shall be sent by Node B.

**Time of Arrival Window Startpoint (ToAWS):** ToAWS represents the time after which the DL data shall arrive to the Node B from Iub. The ToAWS is defined as the amount of milliseconds from the ToAWE. ToAWS is set via control plane. If data arrives before ToAWS a TIMING ADJUSTMENT control frame shall be sent by Node B.

**Time of Arrival (ToA):** ToA is the time difference between the end point of the DL arrival window (ToAWE) and the actual arrival time of DL frame for a specific CFN. A positive ToA means that the frame is received before the ToAWE, a negative ToA means that the frame is received after the ToAWE.

The general overview on the Timing Adjustment procedure is reported in [2].

### 5.3 DCH Synchronisation

DCH Synchronisation procedure is used to achieve or restore the synchronisation of the DCH data stream in DL direction, and as a keep alive procedure in order to maintain activity on the Iur/Iub transport bearer.

The procedure is initiated by the SRNC by sending a DL SYNCHRONISATION control frame towards Node B. This control frame indicates the target CFN.

Upon reception of the DL SYNCHRONISATION control frame, Node B shall immediately respond with UL SYNCHRONISATION control frame indicating the ToA for the DL SYNCHRONISATION control frame and the CFN indicated in the received DL SYNCHRONISATION control frame.

UL SYNCHRONISATION control frame shall always be sent, even if the DL SYNCHRONISATION control frame is received by the Node B within the arrival window.

![Figure 4: DCH Synchronisation procedure](image)

### 5.4 Outer Loop PC Information Transfer [FDD]

Based, for example, on the CRCI values and on the quality estimate in the UL DATA FRAME, SRNC modifies the SIR target used by the UL inner loop power control by including the absolute value of the new SIR target in the OUTER LOOP PC control frame sent to the Node B's.

At the reception of the OUTER LOOP PC control frame, the Node B shall immediately update the SIR target used for the inner loop power control with the specified value.

The OUTER LOOP PC control frame can be sent via any of the transport bearers dedicated to one UE.
5.5 Node Synchronisation

The Node Synchronisation procedure is used by the SRNC to acquire information on the Node B timing.

The procedure is initiated by the SRNC by sending a DL NODE SYNCHRONISATION control frame to Node B containing the parameter T1.

Upon reception of a DL NODE SYNCHRONISATION control frame, the Node B shall respond with UL NODE SYNCHRONISATION control frame, including the parameters T2 and T3, as well as the T1 which was indicated in the initiating DL NODE SYNCHRONISATION control frame.

The T1, T2, T3 parameters are defined as:

- **T1**: RNC specific frame number (RFN) that indicates the time when RNC sends the DL NODE SYNCHRONISATION control frame through the SAP to the transport layer.
- **T2**: Node B specific frame number (BFN) that indicates the time when Node B receives the correspondent DL NODE SYNCHRONISATION control frame through the SAP from the transport layer.
- **T3**: Node B specific frame number (BFN) that indicates the time when Node B sends the UL NODE SYNCHRONISATION control frame through the SAP to the transport layer.

The general overview on the Node Synchronisation procedure is reported in [2].

---

5.6 Rx Timing Deviation Measurement [TDD]

In case the **Timing Advance Applied** IE indicates "Yes" (see [4]) in a cell, the Node B shall, for all UEs using DCHs, monitor the receiving time of the uplink DPCH bursts arriving over the radio interface, and shall calculate the Rx timing deviation. If the calculated value, after rounding, is not zero, it shall be reported to the SRNC in a RX TIMING DEVIATION control frame belonging to that UE. For limitation of the frequency of this reporting, the Node B shall not send more than one RX TIMING DEVIATION control frame per UE within one radio frame.

If the **Timing Advance Applied** IE indicates "No" (see [4]) in a cell, monitoring of the receiving time of the uplink DPCH bursts is not necessary and no RX TIMING DEVIATION control frame shall be sent.
5.7 DSCH TFCI Signalling [FDD]

This procedure is used in order to signal to the Node B the TFCI (field 2). This allows the Node B to build the TFCI word(s) which have to be transmitted on the DPCCH. A transport bearer of any DCH directed to this same UE may be employed for transport over the Iub/Iur.

The procedure consists in sending the DSCH TFCI SIGNALLING control frame from the SRNC to the Node B. The frame contains the TFCI (field 2) and the correspondent CFN. The DSCH TFCI SIGNALLING control frame is sent once every Uu frame interval (10 ms) for as long as there is DSCH data for that UE to be transmitted in the associated PDSCH Uu frame. In the event that the Node B does not receive a DSCH TFCI SIGNALLING control frame then the Node B shall infer that no DSCH data is to be transmitted to the UE on the associated PDSCH Uu frame and will build the TFCI word(s) accordingly.

5.8 Radio Interface Parameter Update [FDD]

This procedure is used to update radio interface parameters which are applicable to all RL's for the concerning UE. Both synchronised and unsynchronised parameter updates are supported.

The procedure consists of a RADIO INTERFACE PARAMETER UPDATE control frame sent by the SRNC to the Node B.

If the RADIO INTERFACE PARAMETER UPDATE control frame contains a valid TPC power offset value, the Node B shall apply the newly provided TPC PO as soon as possible in case no valid CFN is included or from the indicated CFN.
5.9 Timing Advance [TDD]

This procedure is used in order to signal to the Node B the adjustment to be performed by the UE in the uplink timing.

The Node B shall use the CFN and timing adjustment values to adjust its layer 1 to allow for accurate impulse averaging.

![Figure 9A: Timing Advance procedure](image)

5.10 General

5.10.1 Transport bearer replacement

As described in NBAP [4] and RNSAP [6], transport bearer replacement can be achieved by using the Synchronised Radio Link Reconfiguration Preparation procedure in combination with the Synchronised Radio Link Reconfiguration Commit procedure, or by using the Unsynchronised Radio Link Reconfiguration procedure. In both cases the following steps can be discerned:

1) The new transport bearer is established after which 2 transport bearers exist in parallel.
2) The transport channel(s) is/are switched to the new transport bearer.
3) The old transport bearer is released.

In step 1), communication on the old transport bearer continues as normal. In addition, the Node B shall support DL DATA FRAMEs, the DCH Synchronisation procedure (see section 5.3) and the Timing Adjustment procedure (see section 5.2) on the new bearer. This enables the SRNC to determine the timing on the new transport bearer. DL DATA FRAMEs transported on the new transport bearer shall not be transmitted on the DL DPDCH before the CFN indicated in the RADIO LINK RECONFIGURATION COMMIT message.

Regarding step 2), the moment of switching is determined differently in the synchronised and unsynchronised case:

- When using the combination of the Synchronised Radio Link Reconfiguration Preparation procedure and the Synchronised Radio Link Reconfiguration Commit procedure, the UL/DL DATA FRAMEs shall be transported on the new transport bearer from the CFN indicated in the RADIO LINK RECONFIGURATION COMMIT message.
- When using the Unsynchronised Radio Link Reconfiguration procedure, the Node B shall start using the new transport bearer for the transport of UL DATA FRAMEs from the CFN at which the new transport bearer is considered synchronised (i.e. has received a DL DATA FRAME before LTOA [4]).

In both cases, starting from this CFN the Node-B shall support all applicable DCH Frame Protocol procedures on the new transport bearer and no requirements exist regarding support of DCH Frame Protocol procedures on the old transport bearer.

Finally in step 3), the old transport bearer is released.

5.10.2 Transport channel addition

As described in NBAP [4] and RNSAP [6], transport channel addition can be achieved by using the Synchronised Radio Link Reconfiguration Preparation procedure in combination with the Synchronised Radio Link Reconfiguration Commit procedure, or by using the Unsynchronised Radio Link Reconfiguration procedure.
When using the Synchronised Radio Link Reconfiguration Preparation procedure the Node B shall support DL DATA FRAMEs, the Synchronisation procedure (see section 5.3) and the Timing Adjustment procedure (see section 5.2) on the new transport bearer also before the CFN indicated in the RADIO LINK RECONFIGURATION COMMIT message, in order to enable the SRNC to determine the timing on the new transport bearer. DL DATA FRAMEs transported on the new transport bearer before this CFN shall not be transmitted on the DL DPDCH. Starting from this CFN the Node B shall support all applicable DCH frame protocol procedures on the new transport bearer.

When using the Unsynchronised Radio Link Reconfiguration procedure the Node B shall support data frames and control frames when the new transport bearer is established.

### 6 Frame structure and coding

#### 6.1 General

The general structure of a DCH FP frame consists of a header and a payload. The structure is depicted in figure 9B.

![Header Payload](image)

*Figure 9B: General structure of a frame protocol PDU*

The header contains a CRC checksum, the frame type field and information related to the frame type.

There are two types of DCH FP frames (indicated by the FT IE):

- DCH data frame.
- DCH control frame.

The payload of the data frames contains radio interface user data, quality information for the transport blocks and for the radio interface physical channel during the transmission time interval (for UL only), and an optional CRC field.

The payload of the control frames contains commands and measurement reports related to transport bearer and the radio interface physical channel but not directly related to specific radio interface user data.

#### 6.1.1 General principles for the coding

In the present document the structure of frames will be specified by using pictures similar to figure 10.

![Frame structure](image)

*Figure 10: Example of notation used for the definition of the frame structure*
Unless otherwise indicated, fields which consist of multiple bits within a byte will have the more significant bit located at the higher bit position (indicated above frame in figure 10). In addition, if a field spans several bytes, more significant bits will be located in lower numbered bytes (right of frame in figure 10).

On the Iub/Iur interface, the frame will be transmitted starting from the lowest numbered byte. Within each byte, the bits are sent according decreasing bit position (bit position 7 first).

The parameters are specified giving the value range and the step (if not 1). The coding is done as follows (unless otherwise specified):

- Unsigned values are binary coded.
- Signed values are coded with the 2's complement notation.

Bits labelled "Spare" shall be set to zero by the transmitter and shall be ignored by the receiver. The Spare Extension IE indicates the location where new IEIs can in the future be added in a backward compatible way. The Spare Extension IE shall not be used by the transmitter and shall be ignored by the receiver.

6.2 Data frames

6.2.1 Introduction

The purpose of the user data frames is to transparently transport the transport blocks between Node B and SRNC.

The protocol allows for multiplexing of coordinated dedicated transport channels, with the same transmission time interval, onto one transport bearer.

The transport blocks of all the coordinated DCHs for one transmission time interval are included in one frame.

SRNC indicates the multiplexing of coordinated dedicated transport channels in the appropriate RNSAP/NBAP message.

6.2.2 UL DATA FRAME

The structure of the UL DATA FRAME is shown in figure 11.
For the description of the fields, see subclause 6.2.4.

There are as many TFI fields as number of DCH multiplexed in the same transport bearer.

The DCHs in the frame structure are ordered from the lower DCH id (‘first DCH’) to the higher DCH id (‘last DCH’).
The size and the number of TBs for each DCH are defined by the correspondent TFI.

If the TB does not fill an integer number of bytes, then bit padding is used as shown in the figure in order to have the octet aligned structure (ex: a TB of 21 bits requires 3 bits of padding).

There is a CRCI for each TB included in the frame irrespective of the size of the TB, i.e. the CRCI is included also when the TB length is zero. If the CRCIs of one data frame do not fill an integer number of bytes, then bit padding is used as shown in the figure in order to have the octet aligned structure (ex. 3 CRCI bits require 5 bits of padding, but there are no CRCI bits and no padding, when the number of TBs is zero).

The Payload CRC IE is optional, i.e. the whole 2 bytes field may or may not be present in the frame structure (this is defined at the setup of the transport bearer).

### 6.2.3 DL DATA FRAME

The structure of the DL DATA FRAME is shown in figure 12.
Figure 12: DL DATA FRAME structure

For the description of the fields, see subclause 6.2.4.

There are as many TFI fields as number of DCH multiplexed in the same transport bearer.

The DCHs in the frame structure are ordered from the lower DCH id ('first DCH') to the higher DCH id ('last DCH').

The size and the number of TBs for each DCH is defined by the correspondent TFI.
If the TB does not fill an integer number of bytes, then bit padding is used as shown in the figure in order to have the octet aligned structure (ex: a TB of 21 bits requires 3 bits of padding).

The Payload CRC IE is optional, i.e. the whole 2 bytes field may or may not be present in the frame structure (this is defined at the setup of the transport bearer).

### 6.2.4 Coding of information elements in data frames

#### 6.2.4.1 Header CRC

**Description:** Result of the CRC applied to the remaining part of the header, i.e. from bit 0 of the first byte, (the FT IE) to the bit 0 (included) of the last byte of the header) with the corresponding generator polynomial:

\[ G(D) = D^7 + D^6 + D^2 + 1. \]

See clause 7.2.

**Field Length:** 7 bits.

#### 6.2.4.2 Frame Type (FT)

**Description:** Describes if it is a control frame or a data frame.

**Value range:** \{0=data, 1=control\}.

**Field Length:** 1 bit.

#### 6.2.4.3 Connection Frame Number (CFN)

**Description:** Indicator as to which radio frame the first data was received on uplink or shall be transmitted on downlink. See [2].

**Value range:** \{0-255\}.

**Field length:** 8 bits.

#### 6.2.4.4 Transport Format Indicator (TFI)

**Description:** TFI is the local number of the transport format used for the transmission time interval. For information about what the transport format includes, see [3].

**Value range:** \{0-31\}.

**Field length:** 5 bits.

#### 6.2.4.5 Quality Estimate (QE)

**Description:** The quality estimate is derived from the transport channel BER [FDD - or physical channel BER.]

[FDD - If the DCH FP frame includes TB's for the DCH which was indicated as "selected" with the QE-selector IE in the control plane [4] [6], then the QE is the transport channel BER for the selected DCH. If no transport channel BER is available the QE is the physical channel BER.]

[FDD - If the value of the QE-selector IE equals "non-selected" for all DCHs in the DCH FP frame, then the QE is the physical channel BER.]

[TDD - If no transport channel BER is available, then the QE shall be set to 0. This is in particular the case when no transport blocks have been received. The value of QE will be ignored by the RNC in this case.]

The quality estimate shall be set to the transport channel BER [FDD - or physical channel BER] and be measured in the units TrCh_BER_LOG [FDD - and PhCh_BER_LOG respectively] (see [7] and [8]). The quality estimate is needed in order to select a transport block when all CRC indications are showing bad (or good) frame. The UL outer loop power control may also use the quality estimate.

**Value range:** \{0-255\}. 
Granularity: 1.
Field length: 8 bits.

6.2.4.6 Transport Block (TB)

Description: A block of data to be transmitted or received over the air interface. The transport format indicated by the TFI describes the transport block length and transport block set size. See [3].
Field length: The length of the TB is specified by the TFI.

6.2.4.7 CRC indicator (CRCI)

Description: Indicates the correctness/incorrectness of the TB CRC received on the Uu interface. For every transport block included in the data frame a CRCI bit will be present, irrespective of the presence of a TB CRC on the Uu interface. If no CRC was present on the Uu for a certain TB, the corresponding CRCI bit shall be set to "0".
Value range: \{0=Correct, 1=Not Correct\}.
Field length: 1 bit.

6.2.4.8 Payload CRC

Description: CRC for the payload. This field is optional. It is the result of the CRC applied to the remaining part of the payload, i.e. from the bit 7 of the first byte of the payload to the bit 0 of the byte of the payload before the Payload CRC IE, with the corresponding generator polynomial:
\[ G(D) = D^{16} + D^{15} + D^{2} + 1. \] See clause 7.2.
Field length: 16 bits.

6.2.4.9 Spare Extension

Description: Indicates the location where new IEs can in the future be added in a backward compatible way.
Field length: 0-2 octets.

6.3 Control frames

6.3.1 Introduction

Control frames are used to transport control information between SRNC and Node B.

On the uplink, these frames are not combined – all frames are passed transparently from Node B to SRNC. On the downlink, the same control frame is copied and sent transparently to all the Node Bs from the SRNC.

The structure of the control frames is shown in the figure 13.
Control information (cont.)

Figure 13: General structure of the control frames

Control Frame Type IE defines the type of the control frame.

The structure of the header and the payload of the control frames is defined in the following subclauses.

6.3.2 Header structure of the control frames

6.3.2.1 Frame CRC

Description: It is the result of the CRC applied to the remaining part of the frame, i.e. from bit 0 of the first byte of the header (the FT IE) to bit 0 of the last byte of the payload, with the corresponding generator polynomial:

\[ G(D) = D^7 + D^6 + D^2 + 1 \]

See subclause 7.2.

Field Length: 7 bits.

6.3.2.2 Frame Type (FT)

Description: Describes if it is a control frame or a data frame.

Value range: \{0=data, 1=control\}.

Field Length: 1 bit.

6.3.2.3 Control Frame Type

Description: Indicates the type of the control information (information elements and length) contained in the payload.

Value: The values are defined in table 1.

### 6.3.3 Payload structure and information elements

#### 6.3.3.1 TIMING ADJUSTMENT

**6.3.3.1.1 Payload structure**

Figure 14 shows the structure of the payload when control frame is used for the timing adjustment.

![Figure 14: Structure of the payload for the TIMING ADJUSTMENT control frame](image-url)

**6.3.3.1.2 CFN**

**Description:** The CFN value is extracted from the corresponding DL DATA FRAME or DSCH TFCI SIGNALLING control frame.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.

**6.3.3.1.3 Time of Arrival (ToA)**

**Description:** Time difference between the arrival of the DL frame with respect to ToAWE (based on the CFN value in the frame).

**Value range:** [-1280, +1279.875 ms].

**Granularity:** 125 µs.
Field length: 16 bits.

6.3.3.1.4  Spare Extension

Description: Indicates the location where new IEs can in the future be added in a backward compatible way.

Field length: 0-32 octets.

6.3.3.2  DL SYNCHRONISATION

6.3.3.2.1  Payload structure

Figure 15 shows the structure of the payload when control frame is used for the user plane synchronisation.

![Figure 15: Structure of the payload for the DL SYNCHRONISATION control frame]

6.3.3.2.2  CFN

Description: The CFN value is the target CFN and used to calculate ToA.

Value range: As defined in subclause 6.2.4.3.

Field length: 8 bits.

6.3.3.2.3  Spare Extension

The Spare Extension IE is described in subclause 6.3.3.1.4.

6.3.3.3  UL SYNCHRONISATION

6.3.3.3.1  Payload structure

Figure 16 shows the structure of the payload when the control frame is used for the user plane synchronisation.
6.3.3.3.2 CFN

**Description:** The CFN value is extracted from the corresponding DL SYNCHRONISATION control frame.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.

6.3.3.3.3 Time of Arrival (ToA)

The ToA IE is described in subclause 6.3.3.1.3.

6.3.3.3.4 Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.4 OUTER LOOP POWER CONTROL [FDD]

6.3.3.4.1 Payload structure

Figure 17 shows the structure of the payload when control frame is used for the UL outer loop power control.

![Figure 17: Structure of the payload for OUTER LOOP PC control frame](image)

6.3.3.4.2 SIR Target

**Description:** Value (in dB) of the SIR target to be used by the UL inner loop power control.

SIR Target is given in the unit UL_SIR_TARGET where:
UL_SIR_TARGET = 000  SIR Target = -8.2 dB
UL_SIR_TARGET = 001  SIR Target = -8.1 dB
UL_SIR_TARGET = 002  SIR Target = -8.0 dB
...
UL_SIR_TARGET = 254  SIR Target = 17.2 dB
UL_SIR_TARGET = 255  SIR Target = 17.3 dB

Value range: [-8.2...17.3 dB].

Granularity: 0.1 dB.

Field length: 8 bits.

6.3.3.4.3  Spare Extension
The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.5  DL NODE SYNCHRONISATION

6.3.3.5.1  Payload structure
Figure 18 shows the structure of the payload for the DL NODE SYNCHRONISATION control frame.

![Figure 18: Structure of the payload for the DL NODE SYNCHRONISATION control frame](image)

6.3.3.5.2  T1
*Description:* RNC specific frame number (RFN) that indicates the time when RNC sends the frame through the SAP to the transport layer.

*Value range:* As defined in subclause 6.3.3.6.2.

*Field length:* 24 bits.

6.3.3.5.3  Spare Extension
The *Spare Extension* IE is described in subclause 6.3.3.1.4.
6.3.3.6 UL NODE SYNCHRONISATION

6.3.3.6.1 Payload structure

The payload of the UL NODE SYNCHRONISATION control frames is shown in figure 19.

```

Figure 19: Structure of the payload for UL NODE SYNCHRONISATION control frame

6.3.3.6.2 T1

**Description:** T1 timer is extracted from the correspondent DL NODE SYNCHRONISATION control frame.

**Value range:** \{0-40959.875 ms\}.

**Granularity:** 0.125 ms.

**Field length:** 24 bits.

6.3.3.6.3 T2

**Description:** Node B specific frame number (BFN) that indicates the time when Node B received the correspondent DL NODE SYNCHRONISATION control frame through the SAP from the transport layer.

**Value range:** \{0-40959.875 ms\}.

**Granularity:** 0.125 ms.

**Field length:** 24 bits.
6.3.3.6.4  T3

**Description:** Node B specific frame number (BFN) that indicates the time when Node B sends the frame through the SAP to the transport layer.

**Value range:** \( [0, 4095] \text{ ms} \).

**Granularity:** 0.125 ms.

**Field length:** 24 bits.

6.3.3.6.5  Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.7  RX TIMING DEVIATION [TDD]

6.3.3.7.1  Payload structure

Figure 20 shows the structure of the payload when the control frame is used for the Rx timing deviation.

![Figure 20: Structure of the payload for RX TIMING DEVIATION control frame](image)

6.3.3.7.2  Rx Timing Deviation

**Description:** Measured Rx Timing deviation as a basis for timing advance.

**Value range:** \([-256, \ldots, +256 \text{ chips}]\).

\[ (N \times 4 - 256) \text{ chips} \leq \text{Rx Timing Deviation} < (N+1) \times 4 - 256 \text{ chips} \]

With \( N = 0, 1, \ldots, 127 \)

**Granularity:** 4 chips.

**Field length:** 7 bits.

6.3.3.7.3  Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.7.4  CFN

**Description:** The CFN value in this control frame is the CFN when the RX timing deviation was measured.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.
6.3.3.8 DSCH TFCI SIGNALLING [FDD]

6.3.3.8.1 Payload structure

Figure 21 shows the structure of the payload when the control frame is used for signalling TFCI (field 2) bits.

![Diagram of payload structure](image)

**Figure 21: Structure of the payload for the DSCH TFCI SIGNALLING control frame**

6.3.3.8.2 TFCI (field 2)

**Description:** TFCI (field 2) is as described in [4], it takes the same values as the TFCI(field 2) which is transmitted over the Uu interface.

**Value range:** {0-1023}.

**Field length:** 10 bits.

6.3.3.8.3 Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.8.4 CFN

**Description:** Indicator when TFCI(field 2) shall be transmitted on downlink.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.

6.3.3.9 RADIO INTERFACE PARAMETER UPDATE [FDD]

6.3.3.9.1 Payload structure

Figure 22 shows the structure of the payload when the control frame is used for signalling radio interface parameter updates.
6.3.3.9.2 Radio Interface Parameter Update flags

**Description:** Contains flags indicating which information is valid in this control frame.

**Value range:**
- Bit 0: Indicates if the 3\textsuperscript{rd} byte of the control frame payload contains a valid CFN (1) or not (0);
- Bit 1: Indicates if the 4\textsuperscript{th} byte (bits 0-4) of the control frame payload contains a valid TPC PO (1) or not (0);
- Bit 2-15: Set to (0): reserved in this user plane revision. Any indicated flags shall be ignored by the receiver.

**Field length:** 16 bits.

6.3.3.9.3 TPC Power Offset (TPC PO)

**Description:** Power offset to be applied in the DL between the DPDCH information and the TPC bits on the DPCCH as specified in the subclause 5.2 of [12].

**Value range:** \{0-7.75 dB\}.

**Granularity:** 0.25 dB.

**Field length:** 5 bits.

6.3.3.9.4 Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

6.3.3.9.4A CFN

**Description:** The CFN value indicates when the presented parameters shall be applied.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.
6.3.3.10  TIMING ADVANCE [TDD]

6.3.3.10.1  Payload structure

Figure 23 shows the structure of the payload when the control frame is used for timing advance.

![Figure 23: Structure of the TIMING ADVANCE control frame](image)

6.3.3.10.2  CFN

**Description:** The CFN value in this control frame is the frame that the timing advance will occur.

**Value range:** As defined in subclause 6.2.4.3.

**Field length:** 8 bits.

6.3.3.10.3  TA

**Description:** UE applied UL timing advance adjustment.

**Value range:** \{0-252 chips\}.

**Granularity:** 4 chips.

**Field length:** 6 bits.

6.3.3.10.4  Spare Extension

The *Spare Extension* IE is described in subclause 6.3.3.1.4.

---

7  Handling of Unknown, Unforeseen and Erroneous Protocol Data

7.1  General

A frame protocol frame with illegal or not comprehended parameter value shall be ignored. Frame protocol frames sent with a CFN in which the radio resources assigned to the associated Iub data port are not available, shall be ignored.

Frame protocol data frames with CFN value that does not fulfil the requirement set in clause [FDD - 4.2.14 of [9]] [TDD - 4.2.12 of [10]], shall be ignored.
7.2 Error detection

Error detection is provided on frames through a Cyclic Redundancy Check. The length of the CRC for the payload is 16 bits and for the frame header and control frames it is 7 bits.

7.2.1 CRC Calculation

The parity bits are generated by one of the following cyclic generator polynomials:

\[ g_{CRC16}(D) = D^{16} + D^{15} + D^2 + 1 \]

\[ g_{CRC7}(D) = D^7 + D^6 + D^2 + 1 \]

Denote the bits in a frame by \( a_1, a_2, a_3, \ldots, a_{A_i} \), and the parity bits by \( p_1, p_2, p_3, \ldots, p_{L_i} \). \( A_i \) is the length of a protected data and \( L_i \) is 16 or 7 depending on the CRC length.

The encoding is performed in a systematic form, which means that in GF(2), the polynomial for the payload

\[ a_1 D^{A+15} + a_2 D^{A+14} + \ldots + a_{A_i} D^{16} + p_1 D^{15} + p_2 D^{14} + \ldots + p_{15} D^1 + p_{16} \]

yields a remainder equal to 0 when divided by \( g_{CRC16}(D) \) and the polynomial for the header and control frame

\[ a_1 D^{A+6} + a_2 D^{A+5} + \ldots + a_{A_i} D^7 + p_1 D^6 + p_2 D^5 + \ldots + p_{6} D^1 + p_{7} \]

yields a remainder equal to 0 when divided by \( g_{CRC7}(D) \). If \( A_i = 0 \), \( p_1 = p_2 = p_3 = \cdots = p_{L_i} = 0 \).

7.2.1.1 Relation between input and output of the Cyclic Redundancy Check

The bits after CRC attachment are denoted by \( b_1, b_2, b_3, \ldots, b_{B_i} \), where \( B_i = A_i + L_i \).

The parity bits for the payload are attached at the end of the frame:

\[ b_k = a_k \quad k = 1, 2, 3, \ldots, A_i \]

\[ b_k = p_{(k-A_i)} \quad k = A_i + 1, A_i + 2, A_i + 3, \ldots, A_i + L_i \]

The parity bits for the frame header and the control frames are attached at the beginning of the frame:

\[ b_k = p_k \quad k = 1, 2, 3, \ldots, L_i \]

\[ b_k = a_{(k-L_i)} \quad k = L_i + 1, L_i + 2, L_i + 3, \ldots, L_i + A_i \]
