Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for ETSI members and non-members, and can be found in ETSI SR 000 314: "Intellectual Property Rights (IPRs): Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (https://ipr.etsi.org/).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by ETSI 3rd Generation Partnership Project (3GPP).

The present document may refer to technical specifications or reports using their 3GPP identities, UMTS identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables.

The cross reference between GSM, UMTS, 3GPP and ETSI identities can be found under http://webapp.etsi.org/key/queryform.asp.

Modal verbs terminology

In the present document "shall", "shall not", "should", "should not", "may", "need not", "will", "will not", "can" and "cannot" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.

6.4.3.13 Checking the version for MBMS RTP streaming delivery Service interface
6.4.3.13.1 Overview
6.4.3.13.2 Parameters
Foreword

This Technical Specification has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

- Version x.y.z

where:

- x the first digit:
  - 1 presented to TSG for information;
  - 2 presented to TSG for approval;
  - 3 or greater indicates TSG approved document under change control.

- y the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.

- z the third digit is incremented when editorial only changes have been incorporated in the document.

Introduction

The present document has been created as part of the MBMS Transport Protocol and API (TRAPI) work item and is based on the conclusions of TR 26.852 [6] in order to provide application-friendly methods and interfaces to access 3GPP MBMS User services. The present document is primarily targeted for developers of web and user applications and attempts to abstract complex MBMS procedures in simple methods and interfaces. MBMS Client vendors can implement this API and URL to simplify the integration of MBMS User Services.
1 Scope

The present document provides application methods and interfaces between an MBMS-aware application and the UE MBMS Client to access 3GPP MBMS User services. The purpose of the document is the definition of enablers in order to simplify the usage of MBMS in web-centric as well as app-based service environments.

The present document defines several APIs to access MBMS User Services and a URL to access resources available as part of an MBMS User Service. The MBMS User Services are defined in TS 26.346 [5] and are not part of the present document.

2 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document in the same Release as the present document.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the terms and definitions given in TR 21.905 [1] and the following apply. A term defined in the present document takes precedence over the definition of the same term, if any, in TR 21.905 [1].

**Application User Service**: A service for which all associated resources are delivered through an MBMS User Service including broadcast and unicast and which is accessible through the MBMS-API.

**MBMS-API**: An Application Programming Interface between the MBMS Client and the MBMS-Aware application for a specific Application User Service.

**MBMS-aware Application**: An application in the user space that communicates with the MBMS client through APIs as defined in the present document.

**MBMS Client**: A function that implements functionalities defined in TS 26.346 and provides APIs and protocol-related methods to expose relevant functionalities to an MBMS-aware application.

**MBMS-URL**: A Universal Resource Locator that enables a general application to access resources delivered through an MBMS User Service using the MBMS URL handler.

**MBMS-URL Handler**: A logical function that translates the MBMS-URL to a sequence of MBMS-API calls in order to provide resources delivered by MBMS User Services to a general application.

3.2 Abbreviations

For the purposes of the present document, the abbreviations given in TR 21.905 [1] and the following apply. An abbreviation defined in the present document takes precedence over the definition of the same abbreviation, if any, in TR 21.905 [1].

4 Overview

4.1 Introduction

The present document addresses a specific interface for an end-to-end application service, namely the interface between the MBMS client and the MBMS-aware application as shown in Figure 4.1-1. An application service provider may provide content through xMB (see TS 26.346 [5] and TS 29.116 [12]) to the BMSC, but may also provide information directly to an MBMS-aware application. The BMSC uses MBMS User Services as well as MBMS bearer services and unicast bearers to communicate with MBMS client. The present document deals with the interface between the MBMS client and the MBMS-aware application, referred to as MBMS Application Programming Interfaces (MBMS-APIs). The APIs may be used directly by the MBMS-aware application, or the MBMS URL Handler may use the MBMS-APIs after receiving an MBMS URL from a generic application.
According to TS 26.346 [5], three distinct functional layers are defined for the delivery of an MBMS-based service:

1) **Bearers**: Bearers provide the mechanism by which IP data is transported. MBMS bearers as defined in 3GPP TS 23.246 [4] and 3GPP TS 22.146 [2] are used to transport multicast and broadcast traffic in an efficient one-to-many manner and are the foundation of MBMS-based services. MBMS bearers may be used jointly with unicast PDP contexts in offering complete service capabilities.

2) **Delivery Method**: When delivering MBMS content to a receiving application one or more delivery methods are used. The delivery layer provides functionality such as security and key distribution, reliability control by means of forward-error-correction techniques and associated delivery procedures such as file-repair, delivery verification. Three delivery methods are defined, namely download, streaming, and group communication. The present document does not address group communication.

3) **User service**: The MBMS User service enables applications. Different applications impose different requirements when delivering content to MBMS subscribers and may use different MBMS delivery methods.

MBMS User Service architecture is based on an MBMS client on the UE side and a BM-SC on the network side. Details about the BM-SC functional entities are given in figure 4 of TS 26.346 [5].

The BM-SC and UE may exchange service and content related information either over point-to-point bearers or MBMS bearers whichever is suitable. Among others, the following MBMS procedures are defined in TS 26.346 [5]:

- User Service Discovery / Announcement providing service description material to be presented to the end-user as well as application parameters used in providing service content to the end-user.
- MBMS-based delivery of data/content from the BM-SC to the UE over IP multicast or over IP unicast.
- Associated Delivery functions are invoked by the UE in relation to the MBMS data transmission. The following associated delivery functions are available:
  - File repair for download delivery method used to complement missing data.

### 4.3 MBMS Application User Services

#### 4.3.1 Introduction

The MBMS system may provide services to an MBMS-aware application for which all associated resources are delivered through an MBMS User Service including broadcast and unicast. The services may be made accessible through an MBMS-API defined in the present document. The present document defines an initial set of Application User Services and corresponding MBMS-APIs. For each Application User Services, one MBMS-API is defined.

MBMS Application User Services define how an MBMS-Aware application gets access to the content delivered via MBMS user services.

The specification may be extended to add other Application User Services and MBMS-APIs.
The MBMS Application User Services that are covered by the present document are defined in this clause.

### 4.3.2 File Delivery Application User Service

The File Delivery Application User Service provides MBMS Aware Applications with methods to manage the reception of files delivered over MBMS Download Delivery services as defined in TS 26.346 [5]. Some of the interfaces defined allow an application to get information on the available MBMS File Delivery Application Services and possibly on the files scheduled to be carried on these services; to start and stop the capture of files on these services; and to allow the MBMS Client to provide notifications associated with the reception of files. Clause 6.2 provides a complete description and the associated uses for the interfaces in the File Delivery Application Service API and includes an abstract IDL definition for these interfaces.

### 4.3.3 DASH Application User Service

The DASH Streaming Service API defined in clause 6.3 provides MBMS Aware Applications with interfaces to manage the reception of DASH streaming content (as defined in TS 26.247 [7]) delivered over DASH-over-MBMS Streaming Services (as defined in TS 26.346 [5], clause 5.6). Some of the interfaces defined allow an application to get information on the available DASH Streaming Services; to start and stop the reception of DASH streaming content on these services; and to allow the MBMS Client to provide notifications associated with the receptions of DASH streaming content. Clause 6.3 provides a complete description and the associated uses for the interfaces in the DASH Streaming Service API and also includes an abstract IDL definition for these interfaces.

### 4.3.4 MBMS RTP Streaming User Service

MBMS RTP Streaming User Service provides the application with interfaces to access MBMS Streaming Delivery Services as defined in TS 26.346 [5]. The application may request start or stop any available RTP streaming service. Application will receive information about the RTP data.

### 4.4 Specification Outline

The following aspects are defined in the present document:

- The definition of different interfaces as part of client reference architecture in clause 5.
- A set of service APIs (MBMS-APIs) for each application user service as defined in clause 4.3. The definition provide the ability to independently develop MBMS-aware applications and MBMS clients, even for different operating systems and execution environments, but rely on the service APIs to communicate with the MBMS client and to make use of the MBMS functionalities. This is defined in clause 6.
- A set of interface options between the MBMS client and the application to support the transfer of user data. Primary focus is on the communication through HTTP interfaces, as for example DASH or other application services. This is defined in clause 7.
- The mapping of the functionality to a URL handling and abstraction of the services in such environments. This is defined in clause 8.

## 5 Reference Client Architecture

Figure 5.1 shows a general service architecture including a reference client. On the network side, an application and content provider provides media formats to a BM-SC, typically through the xMB interface and initiates services and sessions through the xMB interface. The BMSC establishes MBMS User Services and the lower layers support the delivery of the data through regular LTE unicast as well as MBMS broadcast bearers.

The MBMS-Aware application initiates the communication with the MBMS client using the MBMS-API. The MBMS client identifies the relevant services and provides the delivered user data to MBMS-aware application. Typically, the media formats are provided through interfaces and to functions that conform to well-defined media delivery formats. The MBMS-aware application controls the media client.
In TS 26.346 [5] the interface between the BMSC and the MBMS client for both unicast and broadcast related services and functions are defined. The interface between the MBMS client and the MBMS-aware application is defined in the present document.

The focus of the present document is to define app-developer and web-friendly interfaces and programming structures to enable such an application to interact with the MBMS client.

An application that communicates with the MBMS client through APIs and possibly URL handlers as defined in the present document is referred to as MBMS-aware Application. The MBMS Client is a function that implements functionalities defined in TS 26.346 and provides APIs interfaces to expose relevant functionalities to an MBMS-aware application.

![Figure 5.1: General Reference Architecture for Client](image)

Figure 5.2 shows a specific instantiation for the DASH Streaming Application User Service using the DASH Streaming MBMS-API. In this case the content formats conform to TS 26.247. The DASH client may be viewed as part of the MBMS-aware application, and as 3GPP defines interfaces into a DASH client in TS 26.247 [7] also interfaces to the DASH client function are in focus of the present document.
6 MBMS Application Programming Interfaces

6.1 Overview

6.1.1 Background

Figure 5.2: Client Reference Architecture for DASH-over-MBMS Streaming

The control part of the MBMS-API are used for service discovery, registration, notifications, state changes and other control messages between the MBMS-aware application and the MBMS client and for other control messages. The control part of the MBMS-APIs are defined in clause 6.

The data part interfaces are used to provide content delivered through MBMS User services to the MBMS-aware Application. However, the data is using formats and interfaces that are primarily MBMS independent such that for the application the delivery over MBMS is obscured. MBMS Client to application interfaces for data is primarily introduced in clause 7.
The MBMS API implementation on some High-Level Operating Systems and some application development frameworks is realized as a programmatic library that is linked to the application code and that runs in the application context. That library implementation communicates with a particular MBMS Client implementation and abstracts from the application the implementation-specific interactions with the MBMS Client. The MBMS-API exposes to the application a set of simple interfaces described in the IDL definitions in clauses of the present document; in particular, the IDL makes use of callback functions as the means for the MBMS Client to notify applications of events relevant to the reception of content delivered over MBMS user services. The programmatic library communication with the MBMS Client is implementation-specific, it is not in the scope of the present document, and it can be implemented using different solution approaches (e.g., smartphone High-Level Operating System services, WebSockets, etc.).

It is understood that in some application development frameworks (e.g., HTML/Web Applications), linking a programmatic library to the application is not a solution that is available. In these cases, the callback functions in the IDL definitions as defined in the present document may not be realized programatically as function calls. In particular, the application may need to implement the necessary approach available on these frameworks (or the selected solution approach) to receive event notifications from the MBMS client in place of callback functions. For such frameworks, the implementation of callback functions described in the IDL of the present document is not required. However, the information structures defined on the IDL callback functions are to be communicated to the application when the MBMS Client generates the corresponding event notification to the application using the available (or selected) notification mechanism.

Figure 6.1.1-2 provides an overview of the graphical representation of multiple applications connecting to the MBMS client. Each application uses its own instantiation of the MBMS-API.
Guidelines on API documentation are provided in Annex A.

It is also recommended to separate the description for MBMS client functions and the description of the MBMS-aware application functions as it is expected that they are developed by independent parties.

6.1.2 Parameter description notation

In each Application Service API described in clause 6, the parameters in the API interfaces are described in the following format:

- **dataType** parameterName – description of the parameter.

Each interface parameter is defined via a separate item in the list of parameters. The **dataType** on the item defines the programmatic data type for the parameter named **parameterName**, as described on the IDL for the API; the **dataType** may be a complex structure on the IDL. The **parameterName** provides a name for a parameter on the API interface. A description follows to provide information on the meaning and use for the parameter.

6.1.3 MBMS Client State Model

For each Application Service, the MBMS client maintains certain states for the application and a set of internal parameters. The internal parameters may be updated based on information received from the MBMS system, by time-outs, or by communication with the application. It is recommended that an MBMS client state model for each defined MBMS-API is defined.

6.2 File Delivery Application Service API

6.2.1 Introduction

The File Delivery Application Service API provides MBMS Aware applications with interfaces to manage the reception of files delivered over File Delivery Application User Services. This API is intended to support applications that are running while files are being delivered through MBMS user services as well as applications that are not running to receive information on files received through an MBMS User service, for example as the user may have quit/exited the application.

In order to support applications that may not be currently running while files are being received, the MBMS client may keep received files for a period of time configured by the application, which includes means to collect received files even if the user does not actively interact with the application to consume the received files.

When the application is currently running and can collect the files received over MBMS User services, the MBMS client moves the files to the application space. It is ultimately the application's responsibility to manage the storage of requested files, especially the amount of storage to be used.

Any persistent storage of received files by the MBMS client is only intended to ensure that the received files are made available to the respective requesting application. Once files are moved/copied to the application space, the application is responsible for managing those files.

The IDL for the File Delivery Application Service API is defined in clause B.2.

6.2.2 MBMS Client State Model

6.2.2.1 Overview

Figure 6.2.2.1-1 provides an informative MBMS client state model in order to appropriately describe the messages on the service API. Five different states are defined as listed in Table 6.2.2.1-1.

Note that the state model is defined on the granularity per service and each MBMS-aware application. This means that the MBMS client may at least conceptually have to maintain multiple state machines, namely one for each application/service combination.
The state model does not imply any implementation requirements for an MBMS client, but is used as a model to support the description of the APIs.

State changes may be the result of:

- Requests from the Application
- Timer expiration in the MBMS client
- Information provided by the MBMS User Service (USD, schedule, FDT, file complete)

Figure 6.2.2.1-1: State Diagram

Table 6.2.2.1-1 describes the states for the MBMS client. Detailed descriptions are provided in the following subclauses.
### Table 6.2.2.1-1: States and Parameters of MBMS Client

<table>
<thead>
<tr>
<th>States and Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDLE</td>
<td>In this state the MBMS client does not have any registered application and it may not keep the service parameters up-to-date. For more details see clause 6.2.2.3.</td>
</tr>
<tr>
<td>NON_AVAILABLE</td>
<td>In this state the MBMS client is not available and an application cannot register with the MBMS client. The MBMS client may not be aware of the state, it is only a state perceived by the MBMS-aware application.</td>
</tr>
<tr>
<td>REGISTERED</td>
<td>In this state the MBMS client has registered the application, it may keep the service definition up to date, but it is not providing file capture services to the application(s). For more details see clause 6.2.2.4.</td>
</tr>
<tr>
<td>CAPTURE_NOTIFY</td>
<td>In this state the MBMS client provides file capture for one specific service to a registered application and notifies the application on any received file. For more details see clause 6.2.2.5.</td>
</tr>
<tr>
<td>CAPTURE_BACKGROUND</td>
<td>In this state the MBMS client provides file capture for one specific service to an application without notifying the application on any received file for some agreed time. For more details see clause 6.2.2.6.</td>
</tr>
</tbody>
</table>

### 6.2.2.2 MBMS Client Internal parameters

The MBMS client maintains internal parameters as defined in Table 6.2.2.2-1. Note that the parameters are conceptual and internal and only serve for the purpose to describe message generation on the API calls.

### Table 6.2.2.2-1: Parameters of MBMS Client

<table>
<thead>
<tr>
<th>States and Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_Preconfigurations</td>
<td>MBMS client parameter that provides the maximum time after deregistration that a client still captures files on behalf of an application.</td>
</tr>
<tr>
<td>_maxRegistrationValidityDuration</td>
<td>the time a file that is kept in the MBMS client owned storage location.</td>
</tr>
<tr>
<td>_defaultAvailabilityDeadline</td>
<td>The MBMS client maintains a parameter set per registered app.</td>
</tr>
<tr>
<td>_appId</td>
<td>A unique ID provided by the application and assigned to the app.</td>
</tr>
<tr>
<td>_serviceClass[]</td>
<td>A list of service classes identifying the services the application has access to.</td>
</tr>
<tr>
<td>_registrationValidityDuration</td>
<td>A period of time following the application de-registration over which the MBMS client continues to capture files for the application, see clause.</td>
</tr>
<tr>
<td>_locationPath</td>
<td>The storage location where the application wants the MBMS client to store collected files.</td>
</tr>
<tr>
<td>_backgroundCaptureTimer</td>
<td>Timer on how long files are captured in background.</td>
</tr>
<tr>
<td>_service[]</td>
<td>The MBMS client maintains a parameter list per service. In this context the list is assigned also to one app, but an implementation may share the internal parameter list assigned to a service across multiple apps.</td>
</tr>
<tr>
<td>_serviceID</td>
<td>The service ID for a File Delivery Application service over which the MBMS client collects files for the application.</td>
</tr>
<tr>
<td>_serviceClass</td>
<td>The service class associated with the File Delivery Application service assigned the Service ID.</td>
</tr>
<tr>
<td>_serviceLanguage</td>
<td>The language of the service</td>
</tr>
<tr>
<td>_serviceName[]</td>
<td>The service name, possibly expressed in different languages.</td>
</tr>
<tr>
<td>_name</td>
<td></td>
</tr>
<tr>
<td>_lang</td>
<td></td>
</tr>
</tbody>
</table>
### States and Parameters

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_serviceBroadcastAvailability</td>
<td>The service broadcast availability for the client.</td>
</tr>
<tr>
<td>_fileCaptureRequest[]</td>
<td>A sequence of requested file captures from the application with some parameters.</td>
</tr>
<tr>
<td>- _fileURI</td>
<td>The _fileURI identifies the file(s) as they will also be used on the FLUTE FDTs for the File Delivery Application Service.</td>
</tr>
<tr>
<td>- _disableFileCopy</td>
<td>Allowed values for the _fileURI include:</td>
</tr>
<tr>
<td>- _captureOnce</td>
<td>• The empty string signals that the application is interested in receiving all new files and updates to previously received files.</td>
</tr>
<tr>
<td>- A BaseURL, i.e., a complete path for subdirectory (a prefix) identifying a group of files under that directory.</td>
<td></td>
</tr>
<tr>
<td>- An absoluteURL, i.e., a complete URL that identifies a single file resource.</td>
<td></td>
</tr>
<tr>
<td>_disableFileCopy = when set to true, this signals that the application does not want the MBMS client to make the file available on the application space.</td>
<td></td>
</tr>
<tr>
<td>_captureOnce = when set to true, signals that a file matching a requested via the _fileURI (i.e. a file matching a BaseURL in fileURI, or any file if the fileURI is empty) is to be captured only once.</td>
<td></td>
</tr>
<tr>
<td>_fileURIStatus[]</td>
<td>A sequence of _fileURIStatus[] that states the status of files the application may be interested or the service provides, possibly using scheduling information. The internal parameters store relevant information on the file such as content_type or MD5, if the information is available yet.</td>
</tr>
<tr>
<td>_URI</td>
<td>The delivery state can be:</td>
</tr>
<tr>
<td>_contentType</td>
<td>• FD_RECEIVED - the file is received by the MBMS client and no more updates are expected according to the file schedule.</td>
</tr>
<tr>
<td>_deliveryState</td>
<td>• FD_SCHEDULED - scheduled, if a file schedule is delivered and a file is scheduled, but not yet received.</td>
</tr>
<tr>
<td>_md5</td>
<td>• FD_IN_PROGRESS – the reception of the file is in progress. The delivery schedule records the current upcoming delivery schedules.</td>
</tr>
<tr>
<td>_deliverySchedule[]</td>
<td>The application state may be transitioned to express that</td>
</tr>
<tr>
<td>_start</td>
<td>• the file was moved to the application,</td>
</tr>
<tr>
<td>_stop</td>
<td>• failed if the move failed or</td>
</tr>
<tr>
<td>_appState</td>
<td>• the location path points to an MBMS client controlled space.</td>
</tr>
<tr>
<td>_notified</td>
<td>A _notified flag is provided to indicate if the application has been notified on the reception of the file.</td>
</tr>
<tr>
<td>_fileLocation</td>
<td>_sessionSchedule[]</td>
</tr>
</tbody>
</table>

### 6.2.2.3 MBMS Client Operation in IDLE state

The MBMS client may listen to the User Service Bundle Description and may collect information. However, no binding with the application is in place.

When the MBMS client received the registerFdApp() call as defined in subclause 6.2.3.2, then:

1) The MBMS client checks the input parameters for consistency and sets the internal variables

   a) If appId is an empty string then the MBMS client throws a MISSING_PARAMETER result code in the registerFdResponse() as defined in subclause 6.2.3.3 and abort these steps. If not, the MBMS client sets the internal variable _appId to the value of the parameter.
b) The MBMS client adds each entry in the serviceClassList parameter to its _serviceClass[] record. Note that the serviceClassList parameter may contain an empty service class entry. If an empty service class is provided the MBMS client considers the application to be registered with a service class that is also empty and only allow the application to have access to File Delivery Application Services that are not associated with a serviceClass (i.e., the USD for these services do not have a serviceClass defined).

c) On receiving a registerFdApp() following a deregisterFdApp(), the MBMS client updates the serviceClassList to its _serviceClass[] record in the same way described for the setFdServiceClassFilter() method.

d) If locationPath is not defined, the MBMS client provides means such that the application has access to the files the MBMS Client received on behalf of the application. If the locationPath is defined, the internal variable _locationPath to the value of the parameter.

e) If registrationValidityDuration is not defined, the value of the internal parameter _registrationValidityDuration is set to 0 (zero). If the registrationValidityDuration is defined, the internal variable _registrationValidityDuration is set to this parameter, or to _maxRegistrationValidityDuration if that value is larger than _maxRegistrationValidityDuration.

f) If callback is defined, the MBMS client uses the interfaces in the callback parameter of the registerFdApp() interface to send notification of event occurrences to the Application.

2) generates a response registerFdResponse() as defined in subclause 6.2.3.3 and changes to REGISTERED state:
   a. If the MBMS client functions cannot be activated for any reason, especially if the File Delivery Application Service API did not find an MBMS client available on the UE on which the application is running, the FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE registration response code is sent. The MBMS client may provide a message and may set acceptedFdRegistrationValidityDuration to any arbitrary value.
   b. If the application did not provide a mandatory parameter the MBMS client functions cannot be activated, the MISSING_PARAMETER registration response code is sent. The MBMS client may provide a message and may set acceptedFdRegistrationValidityDuration to any arbitrary value.
   c. If the MBMS client functions can be activated, then
      i. the RegResponseCode is set to REGISTER_SUCCESS registration response code
      ii. a message may be generated
      iii. the MBMS client sets the value of acceptedFdRegistrationValidityDuration to the _registrationValidityDuration.
   d. Sends the response with the above parameters

3) If the MBMS client functions can be activated and the response is sent with a REGISTER_SUCCESS, then MBMS client is in REGISTERED state and uses the REGISTERED parameters to provide the list of matching file delivery services using the information in the User Service Description (USD). If the response is sent with a FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE, then MBMS client is in NOT_AVAILABLE state. If the response is sent with a MISSING_PARAMETER, then MBMS client is in IDLE state.

If the MBMS client receives the getVersion() API call, it shall return version "1.0".

6.2.2.4 MBMS Client Operation in REGISTERED state

For each registered app and the assigned parameters according to Table 6.2.2.2-1, the MBMS client uses the information in the User Service Description as well as its internal state information for the app in _app[] in the
service class list _serviceClass[] to collect and keep up-to-date all internal information for the services of interest for the app, i.e. those that are member of any service class for which the application has interest.

For each MBMS user service for which the USD as defined in TS 26.346 [5] is available in the MBMS client for the service classes registered by the application in _serviceClass[], one service record in the internal parameter _service[] is defined in the MBMS client and continuously updated whenever a new USD is available:

- For each userServiceDescription.name element, a (name, lang) pair is generated and added to the _serviceName[] list with _name set to the value of the USD element, and if present, the _lang set to the value of the associated @lang attribute. If no @lang attribute is present, the _lang parameter is set to an empty string.
- If the attribute userServiceDescription@serviceClass is present, the value of this attribute is assigned to _serviceClass. If not present, the _serviceClass is set to an empty string.
- The value of the attribute userServiceDescription@serviceId is assigned to _serviceId.
- If the attribute userServiceDescription@serviceLanguage is present, the value of this attribute is assigned to _serviceLanguage. If not present, the _serviceLanguage is set to an empty string.
- The _serviceBroadcastAvailability is continuously updated set it to BROADCAST_AVAILABLE, if broadcast is available (if the UE is in broadcast coverage of the service), if not, it is set to BROADCAST_UNAVAILABLE (if the UE is NOT in broadcast coverage of the service).
- If the userServiceDescription.schedule element is present then the MBMS client uses the information in the schedule description fragment to generate the internal _fileURI[] and _sessionSchedule[] list and keep up to date as a result of USD updates. The MBMS client should only include _fileUri[] list if there is a current or a future scheduled transmission of that file. The MBMS client shall only include _sessionSchedule[] records if the _stop value is in the future. The _deliveryState is set appropriately, e.g. to FD_SCHEDULED if the file is scheduled and FD_IN_PROGRESS, if the FDT is available, but the file reception is not yet completed.

If updates are provided and added to the _service[] parameter, the MBMS client should send a fdServiceListUpdate() callback as defined in clause 6.2.3.17.

When the getFdServices() call is received by as defined in clause 6.2.3.4, the MBMS client sets the parameters as follows:

- If the _service[] list is empty, then an empty list is returned.
- For each MBMS user service in the _service[] list, one service record is generated as follows:
  - The value of the attribute _serviceId is assigned to serviceId.
  - The value of the attribute _serviceClass is assigned to serviceClass.
  - The value of _serviceLanguage is assigned to serviceLanguage.
  - For each record in the _serviceName[] one serviceNameList entry is generated and:
    - the name is set to the value _name,
    - the language is set to the value _language.
  - The value of _serviceBroadcastAvailability is assigned to serviceBroadcastAvailability.
- If at least one _sessionSchedule[] record is present then:
  - The activeDownloadPeriodStartTime is set to the value of earliest _start time of any entry in the _sessionSchedule[] such that the corresponding _stop time is in the future.
  - The activeDownloadPeriodStopTime is set to the value of the _stop time of the entry selected earliest start time.
- If no _sessionSchedule[] record is present, or the _start and _stop on existing entries in _sessionSchedule[] are in the past:
  - The activeDownloadPeriodStartTime is set to 0.
  - The activeDownloadPeriodStopTime is set to 0.

When the setFdStorageLocation() method as defined in 6.2.3.5 is received by the MBMS client, the MBMS client runs the following steps:

- It updates the internal variable _locationPath to the parameter value of locationPath provided in the call.

NOTE: The MBMS client provides any new files for that application at the locationPath, but not ongoing file capture.

- If the storage location is empty the MBMS client selects a local directory on the device, which the application can access directly via file access interfaces or via HTTP GET methods (see 6.2.2.5 and 6.2.2.6).

When the setFdServiceClassFilter() is received, the MBMS client runs the following steps:

- It replaces the internal variable _serviceClass[] with the parameter values provided in serviceClassList.
  
  o Note that this does not necessarily change the ongoing MBMS client operation, e.g. capturing

- The MBMS client issues a fdServiceListUpdate() notification as defined in clause 6.2.3.17 to the application to notify it of this effect.

When the startFdCapture() method is received, the MBMS client runs the following steps:

- The MBMS client checks for errors and if necessary, the fdServiceError() notification as defined in clause 6.2.3.18 is initiated.

- If the requested fileURI matches an existing outstanding startFdCapture() request as recorded on the _fileCaptureRequest[], the internal error code is set to FD_DUPLICATE_FILE_URI and the fdServiceError() notification as defined in clause 6.2.3.18 is initiated.

- If the requested fileURI is ambiguous in the following manner

  - The fileURI is an absolute URL or a Base URL and there is an existing outstanding startFdCapture() with an empty fileURI, or
  
  - fileURI is an absolute URL and there is an existing outstanding startFdCapture() with a Base URL in the fileURI that is base URL for the absoluteURL.

then, the internal error code is set to FD_AMBIGUOUS_FILE_URI and the fdServiceError() notification as defined in 6.2.3.18 is initiated.

- Otherwise, The fileURI is added to the internal list of the MBMS client _fileCaptureRequest[]. Any overlapping entry should be avoided.

- The MBMS client removes existing outstanding startFdCapture() requests from _fileCaptureRequest[] when the requested fileURI on a startFdCapture() is broader (i.e., superseding older requests) than these existing outstanding startFdCapture() requests; this request consolidation will not impact ongoing file downloads, specifically:

  - When fileURI is empty on the new startFdCapture(), all existing outstanding startFdCapture() are removed.
- When fileURI is a Base URL, existing outstanding startFdCapture() requests with an absolute URL are removed if the new fileURI in the request is a base URL for the absolute URL on these existing outstanding startFdCapture().

- The _disableFileCopy is set to the value of disableFileCopy.

- The _captureOnce is set to the value of captureOnce.

- The MBMS client is in CAPTURE_NOTIFY mode.

Whenever there has been a change to the parameters reported to the application in response to a getFdServices() API, i.e. in the internal service class list _serviceClass[] to add a new service record to the list or a change in one of the following internal parameters in the service record in the _serviceLanguage, _serviceName[], _serviceBroadcastAvailability, or updates to the _fileURIStatus[] adding new _URIs with _deliveryState set to FD_SCHEDULED, the MBMS client notifies application with fdServiceListUpdate() as defined in clause 6.2.3.17.

When the deregisterFdApp() is received, the client moves to IDLE state.

### 6.2.2.5 MBMS Client Operation in CAPTURE_NOTIFY Mode

The MBMS client carries out all actions as in the REGISTERED state.

For one MBMS user service identified with one service record in the internal parameter _service[] with a specific _serviceID the MBMS client continuously updates the internal parameters for this service.

In addition, for each fileCaptureRequest[] record in the service record:

1) If the _fileUri is empty then the MBMS client receives all new and updated files delivered on this MBMS service with service ID serviceId. Updated files may be discovered by a change of the MD5 in the FDT.

2) If the _fileUri is a complete absolute URI, then the MBMS client receives only that file delivered on the MBMS service with service ID serviceId which has a matching URL as the fileURI parameter if the file is received for the first time or is a new version since the last reception.

3) If the _fileUri is a Base URI as defined in RFC 3986 [add reference], then the MBMS client receives all new and updated files delivered on the MBMS service with service ID serviceId which are delivered through the MBMS user service with a matching BaseURL of the one defined in the fileURI parameter.

Furthermore, the MBMS Client performs the actions as follows.

4) For each file announced via the file schedule element and matching any of the capture requests in fileCaptureRequest[]:
   - the MBMS client create an entry in the _fileURIStatus[] adding the _URI and delivery schedules _deliverySchedule[] and sets the _deliveryState to FD_SCHEDULED.
   - The MBMS Client should send a fdServiceListUpdate() callback as defined in clause 6.2.3.17.

5) For each file announced in the FDT and matching any of the capture requests in fileCaptureRequest[], the MBMS client:
   - Updates or creates an entry adding the _URI.
   - Sets the _deliveryState to FD_IN_PROGRESS.
   - Does not download the same version of the file if the Content-MD5 in the File element of the FDT Instance is the same as a previously received version of the file.
   - If a MIME type was defined via the FDT describing that file transmission, the _contentType parameter is set to the value of the Content-Type as in the File entry of the FDT. If the MIME type is not defined, the _contentType parameter is set to an empty string. The MD5 may be extracted from the FDT if present.
6) For each successfully received file announced in the FDT and matching any of the capture requests in fileCaptureRequest[]:

- The MBMS client updates the _deliveryState to FD_RECEIVED.
- If the _locationPath is defined and if the MBMS client is successful in copying/moving the collected file to the directory in _locationPath, the MBMS client sets the _appState to moved and the _fileLocation pointing to the file in the _locationPath.
- If the _locationPath is empty (_appState indicates that MBMS client space needs to be used or that the MBMS client selected a location on the app space) or if the MBMS client is not successful in copying/moving the collected file to the directory defined in _locationPath (_appState is set to indicate the failure) then the _fileLocation is set to:
  - A complete file name (including the directory path) on the UE local file system where the file can be accessed by the application. The file may be stored under an MBMS client defined directory that is accessible to the application.
  - An HTTP URL where the MBMS Aware Application can retrieve the file using the HTTP GET method. This format may be used when the file is stored on a location that is not directly accessible to the application.
- The MBMS client announces it through fileAvailable() notification as defined in clause 6.2.3.8 to the app by setting the parameters as follows:
  - The serviceId is set to the _serviceID.
  - The fileUri is set to the value of _URI.
  - The fileLocation is set to the value of the _fileLocation.
  - The contentType is set to the _contentType.
  - If the _appState is failed or internal, the MBMS client sets the value of the availabilityDeadline to the internal variable _defaultAvailabilityDeadline, otherwise sets the value to 0.
  - The internal _notified flag is set to true.
- If the _captureOnce is set to true, the corresponding fileURI is excluded/removed from the _fileCaptureRequest[] and from the internal _fileURIStatus[] list.

7) For each non-successfully received file announced in the FDT and matching any of the capture requests in fileCaptureRequest[] (after file repair failed or when file repair is not defined for the service):

- The MBMS client sets the _deliveryState to FD_SCHEDULED
- The MBMS client announces it through fileDownloadFailure() notification as defined in clause 6.2.3.10 to the app with the following parameter settings:
  - The serviceId is set to the _serviceID.
  - The fileUri is set to the value of _URI.

Whenever the in the internal _fileURIStatus[] was changed, the MBMS client should issue a fileDownloadStateUpdate() notification as defined in clause 6.2.3.15 with the following parameters:

- The serviceId is set to the _serviceID.

The MBMS client moves to REGISTERED state if the _fileCaptureRequest[] is empty.

When the getFdAvailableFileList() API call as defined in clause 6.2.3.12 is received, the MBMS client runs the following steps:
- For the service with internal _serviceId set to the input parameter serviceID, for each successfully received file (i.e. internal _deliveryState being received) that matches a _fileCaptureRequest[] and is included in the _fileURIStatus[] record with an internal status _notified set to false, the following parameters are assigned
  - The fileUri is set to the value of _URI.
  - The fileLocation is set to the value of the _fileLocation.
  - The contentType is set to the _contentType.
  - If the _appState is failed or internal, the MBMS client sets the value of the availabilityDeadline to the internal variable _defaultAvailabilityDeadline, otherwise sets the value to 0.
  - The internal status _notified set to true.

When the MBMS client receives a stopFdCapture() request as defined in clause 6.2.3.13 that matches an entry in the internal parameter _fileCaptureRequest[]:

- The MBMS client removes this entry from the _fileCaptureRequest[] record in order to stop any on-going and future file receptions that match that particular record.
- The MBMS client should keep records of outstanding startFdCapture() requests that are unambiguous such that a stopFdCapture() can unambiguously remove an entry in the internal parameter _fileCaptureRequest[] from an earlier startFdCapture() request.
- The MBMS client may also send a failure indication via the fdServiceError() with the FD_AMBIGUOUS_FILE_URI error code when the requested fileURI on a stopFdCapture() is more specific than an existing outstanding startFdCapture() requests that is broader:
  - When fileURI is an absolute URL or a Base URL and there exists an entry in the internal parameter _fileCaptureRequest[] with an empty fileURI.
  - When fileURI is an absolute URL and there exists an entry in the internal parameter _fileCaptureRequest[] with an empty fileURI. With a Base URL in the _fileURI that is base URL for the absoluteURL.
  - The MBMS client may send a failure indication via the fdServiceError() with the FD_STOP_FILE_URI_NOT_FOUND error code to any stopFdCapture() request that does not match an entry in the internal parameter _fileCaptureRequest[].

When the getFdActiveServices() API call as defined in clause 6.2.3.14 is received, the MBMS client runs the following steps:

- For the service with internal _serviceId set to the input parameter serviceID, for each entry in the internal parameter _fileCaptureRequest[] one record in the response is set with the fileUri set to the value of _URI.

When the MBMS Client receives getFdDownloadStateList() API call as defined in clause 6.2.3.16, it runs the following steps:

- For the service with internal _serviceId set to the input parameter serviceID, for each file that matches a _fileCaptureRequest[] and is included in the _fileURIStatus[] record, the following parameters are assigned:
  - The fileUri is set to the value of _URI.
  - The state is set to the internal value _deliveryState.

If the deregisterFdApp() API call invoked the MBMS client:

- And if the _fileCaptureRequest[] record contains no more entries or the _registrationValidityDuration is set to zero, the MBMS client moves to IDLE state.
- If the _fileCaptureRequest[] record contains one or more entries, the MBMS client moves to CAPTURE_BACKGROUND state.

6.2.2.6 MBMS Client Operation in CAPTURE_BACKGROUND State

When the MBMS client enters this state, the internal _backgroundCaptureTimer is set to _registrationValidityDuration and started. The MBMS client remains in this state until this timer expires, or the application invokes a new registerFdApp() API call.

Once the time for the registration validation has expired, the MBMS client clears all context for the app and returns to IDLE state for the app. Until this is the case, the MBMS client performs the following actions.

The MBMS client carries out all actions as in the CAPTURE_NOTIFY state, except for those associated with sending notifications (invoking call-back functions) to the app.

While an MBMS Aware application is deregistered and files are received for that application, if multiple versions of the same file (i.e., the same fileURI but different Content-MD5 in the FDT for a File Delivery Application Service) are received, only the last file version received is kept by the MBMS client and made available to the application after the new registration.

If the application is not currently registered at the time and the download of files for that application fails, the MBMS client is not able to inform application.

For one MBMS user service identified with one service record in the internal parameter _service[] with a specific _serviceID the MBMS client continuously updates the internal parameters for this service. Whenever the delivery state is changed in the state, the internal _notified flag is set to false.

6.2.3 Methods

6.2.3.1 Overview

Table 6.2.3.1-1 provides an overview over the methods defined for the File Delivery Application Service API. Different types are differentiated, namely state changes triggered by the app, status query of the app to the client, parameter updates as well as notifications from the client. The direction of the main communication flow is provided between the application (A) and the MBMS client (C).

### 6.2.3.2 Registration

#### 6.2.3.2.1 Overview

This clause defines registerFdApp() interface.

An MBMS Aware Application calls the registerFdApp() interface to register with the MBMS Client to consume File Delivery Application Services. The registerFdApp() interface has two purposes:

1) It signals to the MBMS Client that an application is interested to consume MBMS services. This registration may be considered as pre-condition for the MBMS Client to keep checking for updates to the File Delivery Application Services defined.

2) It allows the application to identify its callback listeners defined in the File Delivery Application Service API for the MBMS Client to provide asynchronous notifications to the application on relevant events associated with the reception of files.

**NOTE:** Since some application development frameworks do not support callback functions, an MBMS Aware Application for these frameworks will not provide callback listeners in the registerFdApp() interface. Instead, the application will implement the necessary approach available on these frameworks to receive event notifications from the MBMS Client in place of callback functions. The notifications implemented on these frameworks will include the same information content as defined on the structures for the IDL callback functions.

Figure 6.2.3.2.1-1 shows a call flow and the usage of the registerFdApp() interface.
6.2.3.2.2 Parameters

The parameters for the registerFdApp() API are:

- **string appId** – provides a unique ID for the application registering with the MBMS client, which uses this identity to maintain state information (e.g., capture requests and captured files) for a particular MBMS Aware Application. The uniqueness of the ID is in the context of any application that may possibly register with MBMS client. Uniqueness is typically provided at the platform level.

- **any platformSpecificAppContext** – a platform-specific context for the registering application that enables the MBMS client to get extra information about the application that may be need to enable the application to have access to MBMS services, e.g., to enable application authentication or to enable the application to communicate with the MBMS client via platform (e.g., HLOS) services.

- **sequence<string> serviceClassList** – provides a comma-separated list of service classes which the application is interested to register. Each service class string can be any string or it may be empty.

- **StorageLocation locationPath** – identifies a local directory available on the device storage, which the application can access and where successfully collected files can be copied/moved before notifying that the file is available to the application. The storage location is a string pointing to a directory, or it may be empty, if no location is provided.

- **unsigned long registrationValidityDuration** – the period of time in seconds following the application de-registration (via the application call to deregisterFdApp(), or when the MBMS client detects that the application is no longer running), and possible exit, over which the eMBMS client still considers the application registered for the purpose of fulfilling any outstanding startFileCapture() requests. The default value of this option is 0 (zero) which signals to the MBMS client to clear any outstanding startFdCapture() requests for that application upon its de-registration, and possible exit.

**NOTE 1:** The registrationValidityDuration is provided via the registerFdApp(), rather than via a deregisterFdApp(), to handle abnormal application termination conditions (e.g., application crash or it is terminated by the HLOS) before the application has a chance to invoke the deregisterFdApp().

- **ILTEFileDeliveryServiceCallback callBack** – provides the MBMS client with the call back functions associated with File Delivery Application Service APIs for the registering MBMS Aware Application.
NOTE 2: The callback element in the IDL description is optional and only included when the application development framework supports programmatic callback interfaces. If callbacks are not supported on a given application development framework, the same information content as defined on the callback structures is to be provided to the application via the notification method available with that development framework when the respective condition is met.

6.2.3.2.3 Pre-Conditions

The application is assigned a unique application ID appId in the context of its operation (e.g., a smartphone HLOS) with the MBMS client.

The application is pre-configured with the set of service classes that allows it to consume the File Delivery Application Services associated with these service classes.

The application manages the storage of requested files, especially the amount of storage to be used.

The application may use this method at launch or after a deregisterFdApp() has been called.

The application assumes the client in IDLE state or CAPTURE_BACKGROUND state.

The MBMS client may be configured to support a maximum _maxRegistrationValidityDuration.

6.2.3.2.4 Usage of Method for Application

The application uses the method registerFdApp() to register with the MBMS Client to consume File Delivery Application Services.

The application provides its appId and, if applicable, some platform specific application context, platformSpecificAppContext.

The application provides the set of service classes which the application is interested to register.

Setting the registrationValidityDuration enables the application to allow the MBMS client to capture files in the background when the application is not currently running; typically after invoking the deregisterFdApp() or after crashing. The application developer should be aware that received files belong to the application and that the MBMS client does not provide content management functions beyond reception and temporary storage of received files in between consecutive runs of the application.

When the application is not interested in receiving files from File Delivery Application Services while the application is not running, the application should set the registrationValidityDuration to 0 (zero). When the application is interested in receiving files from File Delivery Application Services while the application is not running, the application should set the registrationValidityDuration to a non-zero value and it should call the deregisterFdApp() interface before stop running to disable notifications from the File Delivery Services APIs. If the MBMS client can determine that an application has crashed and exited without invoking the deregisterFdApp() interface, the MBMS client will assume that the application had called the deregisterFdApp() before exiting.

On issuing a registerFdApp() following a deregisterFdApp(), the application will include the same serviceClassList used on the last registerFdApp() or setFdServiceClassFilter() to signal interest on the same set of service classes identified before. The application may change the list of registered service classes by providing a serviceClassList as part of a new registerFdApp() request, similarly to using the setFdServiceClassFilter() method.

The application should define a local directory locationPath on the device, where successfully collected files will be copied/moved before making the file available to the application. If no directory is defined, the locationPath should be an empty string.

The application selects a value for the parameter registrationValidityDuration to constrain the amount of storage the MBMS client will use to collect and keep application-requested files in the MBMS client storage space while the application is not currently running (e.g., has de-registered or crashed). The amount of files cached for an application that does not collect its files may impact the MBMS client's ability to collect files for other applications. In selecting a value for the registrationValidityDuration the following should consider:
- The frequency and amount of files received during the selected registrationValidityDuration. For instance, assuming that 100MB worth of files are delivered every day:

- The application could select a registrationValidityDuration of Nx24h (e.g., N=10) to request the MBMS client to store at most Nx100MB (e.g., 1GB) if the application is not run by the user in Nx24h.

- The application could ask its user (or have a preconfigured behavior on) how long the user wants files to be collected in-between the user's access to files delivered to the application. If the user selects a long period (e.g., 2months) the application should not use that large values as the registrationValidityDuration (e.g., this could mean 6GB in the example above). Instead, the application should include behaviors to periodically re-register (e.g., every 5days) and collect received files to manage storage of its application files. Leaving those files in the MBMS client storage space (e.g., 6GB) could exceed the MBMS client storage space allowance and impact the reception of files for other applications.

- The relevance of older vs. newer files when managing the storage for files received if the user does not access the application over a long period of time.

- The application could ask the user how much storage to use for received files and whether to delete older files (newer files preferred), or stop new downloads (older preferred), or however else the application chooses to support managing received files.

- As described above, in the absence of the user launching the application for File Delivery Application Services with outstanding startFdCapture() requests, that application should automatically re-register (e.g., every 5days as discussed above) with the MBMS client with a periodicity not greater than registrationValidityDuration and retrieve files captured during the period the application was not currently registered.

- The application should then manage the downloaded files with respect to the amount of storage consumed by files of that application. For instance, the application may prioritize retaining newer versus older files or let the registrationValidityDuration expire (therefore causing the MBMS client to stop continued file downloads for that application) if the user does not consume file contents for that application.

EXAMPLE 1: Daily headline news application allows the user to collect files from two File Delivery Application Services with new/updated video clip files downloaded twice every day.

- The application registrationValidityDuration is 2days, it re-registers with the MBMS client every 1.5 days and it keeps only the files that are no more than two days old, e.g., as configured by the user.

EXAMPLE 2: Weekly magazine application allows the user to collect files from a File Delivery Application Service with new/updated files for selected electronic versions of weekly magazines downloaded once a week.

- The application registrationValidityDuration is 15 days, it re-registers with the MBMS client every 7 days and it keeps only the files that are no more than three weeks old, e.g., as configured by the user.

### 6.2.3.2.5 Expected MBMS Client Actions

When this method is received, the MBMS client registers the app. For more details refer to clause 6.2.2.3.

### 6.2.3.2.6 Post-Conditions

The application expects a registerFdResponse() as defined in clause 6.2.3.3.

### 6.2.3.3 File Delivery Application Service Registration Response

#### 6.2.3.3.1 Overview

This subclause defines the registerFdResponse() call.

As illustrated in Figure 6.2.3.2.1-1, the MBMS client responds to an Application call to the registerFdApp() API with a registerFdResponse() call back providing the result of the registration request.
6.2.3.3.2  Parameters

The parameters for the registerFdResponse() API are:

- EmbmsCommonTypes::RegResponseCode value – provides a result code on the registration request. The allowed values are:
  - REGISTER_SUCCESS – indicates that the registration has been processed successfully and the application can proceed with other API interactions with the MBMS client for File Delivery Application Services.
  - FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE – Indicates that the registration has failed since the File Delivery Application Service API did not find an MBMS client available on the UE on which the application is running and no MBMS service will be available to the application.
  - MISSING_PARAMETER – indicates that the registration has failed since one or more of the required parameter was missing.

- string message – provides an associated text description of the error message. The message may be empty.

- unsigned long acceptedFdRegistrationValidityDuration – when returning REGISTER_SUCCESS, this parameter indicates the registration validity duration the MBMS client will provide to the registering application.

6.2.3.3.3  Pre-Conditions

The MBMS client has received a call via the registerFdApp() API with the parameters documented in clause 6.2.3.2.2.

6.2.3.3.4  Expected MBMS Client Actions

Based on the parameters of the registerFdApp(), the MBMS client provides the response and changes the state. For more details see clause 6.2.2.3.

6.2.3.3.5  Usage of Method for Application

Once the application receives a the registerFdResponse() with the RegResponseCode set to REGISTER_SUCCESS, the application can proceed with other API interactions with the MBMS client, for instance, by issuing startFdCapture() requests.

Based on the response in acceptedFdRegistrationValidityDuration the application should adjust its expectations accordingly if the value returned is not what was requested.

If the MBMS client is temporarily in NOT_AVAILABLE, if the registerFdResponse() signaled a failure with a FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE, the application may periodically recheck if the state of the MBMS client changes by retrying the registerFdRequest() API.

6.2.3.3.6  Post-Conditions

If the MBMS client functions cannot be activated and once the response is sent with a FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE, then MBMS client is at least temporarily in NON_AVAILABLE state.

If the MBMS client functions cannot be activated and once the response is sent with a MISSING_PARAMETER, then MBMS client is at least temporarily in IDLE state.

If the MBMS client functions can be activated and a response is sent with REGISTER_SUCCESS, then MBMS client is in REGISTERED state with the REGISTERED state parameters as set above.
6.2.3.4 Getting information on available File Delivery Application Services

6.2.3.4.1 Overview

This clause defines the getFdServices() interface.

The getFdServices() interface returns the complete list of available File Delivery Application Services information. After a successful registration with the MBMS client, the MBMS Aware Application can use the getFdServices() API to discover the available File Delivery Application Services associated with the service classes registered via the registerFdApp(). Also the MBMS client may use the getFdServices() API after receiving a fdServiceListUpdate() call back notification to changes to the available File Delivery Application Services.

6.2.3.4.2 Parameters

The getFdServices() API does not have any input parameters.

The getFdServices() API returns a list describing the available File Delivery Application Service, where each service is described by the following output only parameters:

- sequence<ServiceNameLang> serviceNameList – optionally provides a list of the service title name in possibly different languages. Each (name, lang) pair defines a title for the service on the language indicated.
  - string name – offers a title for the user service on the language identified in the lang parameter.
  - string lang – identifies a natural language identifier per IETF RFC 3066 [10].
- string serviceClass – identifies the service class which is associated with the service.
- string serviceId – provides the unique service ID for the service. The uniqueness is among all services provided by the BMSC.
- string serviceLanguage – indicates the available language for the service and represented as an identifier per IETF RFC 3066 [10].
- EmbmsCommonTypes::ServiceAvailabilityType serviceBroadcastAvailability – signals whether the UE is currently in the broadcast coverage area for the service.
  - The possible values are for a File Delivery Application Service:
    - BROADCAST_AVAILABLE – if content for the service is broadcast at the current device location.
    - BROADCAST_UNAVAILABLE – if content for the service is not broadcast at the current device location.
- sequence<string> fileUriList – optionally provides a list of file names for the files that are currently scheduled to be transmitted.
- EmbmsCommonTypes::Date activeDownloadPeriodStartTime – signals the current/next active File Delivery Application Service start time, when files start being broadcast over the air.
- EmbmsCommonTypes::Date activeDownloadPeriodEndTime – signals the current/next active File Delivery Application Service stop time, when files stop being broadcast over the air.

Note that the available File Delivery Application Service list may be empty.

6.2.3.4.3 Pre-Conditions

The MBMS client is in REGISTERED state or in CAPTURE_NOTIFY state and may or may not have acquired any USD information for services that are included in the service class list.

The MBMS client may have updated internal _service[] list.
6.2.3.4.4 Expected MBMS Client Actions

When this method is received, the MBMS client returns its internal parameters. For more details see clause 6.2.2.3.

6.2.3.4.5 Usage of Method for Application

The usage of the parameters serviceNameList, serviceClass, serviceBroadcastAvailability, and serviceLanguage is typically up to the application.

The fileUriList may be used by the application for selective file reception, e.g. when used together with startFdCapture() as defined in clause 6.2.3.7.

The application should use this call right after the registerFdResponse() notification as defined in clause 6.2.3.3 is received or after the fdServiceListUpdate() notification as defined in 6.2.3.17 is received.

The application shall use the serviceId to identify the service in subsequent communication with the MBMS client to manage the files to be captured on that service for the application.

The parameters activeDownloadPeriodStart Time and activeDownloadPeriodEndTime provides the application the ability to determine the current broadcast state for the service as follows:

- If the current time is such that activeDownloadPeriodStart Time ≤ current time ≤ activeDownloadPeriodEndTime, files may be captured for the service at the current time.

- If the activeDownloadPeriodStart Time is in the future, there is currently file capturing expected for the service, but delivery is currently scheduled to start at this advertised time.

- If the activeDownloadPeriodStart Time is set to zero, there is no currently defined broadcast schedule time for the service.

- If the activeDownloadPeriodEndTime is in the past, or there are no activeDownloadPeriodStart Time and no activeDownloadPeriodEndTime defined for the service, then there is currently no broadcast being made for the service, and there is no currently scheduled broadcast time for the service.

6.2.3.4.6 Post-Conditions

This call does not change the MBMS client state.

6.2.3.5 Establishing the location where files are stored for an application

6.2.3.5.1 Overview

This clause defines setFdStorageLocation().

While an application is actively registered with the MBMS client to consume File Delivery Application Services, the MBMS Aware Application can call the setFdStorageLocation() API to set or update the location where files collected for the application are to be stored. This message flow is shown in Figure 6.2.3.5.1-1.
6.2.3.5.2 Parameters
The parameters for the setFdStorageLocation() method are:

- StorageLocation locationPath – see clause 6.2.3.2.2.

6.2.3.5.3 Pre-Conditions
The application is registered with the MBMS client to consume File Delivery Application Services, and MBMS client is in REGISTERED or CAPTURE_NOTIFY state.

6.2.3.5.4 Usage of Method for Application
The MBMS Aware Application may invoke the setFdStorageLocation() API call to update the previously defined storage location. This includes the case that the storageLocation was not set previously.

It may also use this API call if it receives an insufficient storage notification as defined in clause 6.2.3.19.

6.2.3.5.5 Expected MBMS Client behaviour
When this method is received, the MBMS client updates the internal parameters and notifies the client. For more details see clause 6.2.2.3.

6.2.3.5.6 Post-Conditions
The MBMS client internal variable _locationPath for this application is updated. No state change is applied.
### 6.2.3.6 Updating the registered service classes

#### 6.2.3.6.1 Overview

This clause defines `setFdServiceClassFilter()`.

While an application is actively registered with the MBMS client to consume File Delivery Application Services, the MBMS Aware Application can call the `setFdServiceClassFilter()` API to update the list of service classes the application wants to be registered with, see Figure 6.2.3.6.2-1.

![Sequence diagram for updating the registered service classes for an application](image)

**Figure 6.2.3.6.2-1: Sequence diagram for updating the registered service classes for an application**

#### 6.2.3.6.2 Parameters

The parameters for the `setFdServiceClassFilter()` method are:

- `sequence<string> serviceClassList` – see clause 6.2.3.2.2.

#### 6.2.3.6.3 Pre-Conditions

The application is actively registered with the MBMS client to consume File Delivery Application Services, and MBMS client is in `REGISTERED` state or `CAPTURE_NOTIFY` for the application.

#### 6.2.3.6.4 Usage of Method for Application

The MBMS Aware Application may invoke the `setFdServiceClassFilter()` API to update the previously defined list of service classes that includes additional service classes or includes fewer service classes than the list of service classes.

The application should be aware that the updates are only active once an `fdServiceListUpdate()` notification is received that confirms the new service class filters.
6.2.3.6.5 Expected MBMS Client Actions

When this method is invoked, the MBMS client updates the internal parameters and notifies the client.

6.2.3.6.6 Post-Conditions

The MBMS client issues an `fdServiceListUpdate()` notification as defined in clause 6.2.3.17. No state change is applied.

6.2.3.7 Start File Delivery Capture

6.2.3.7.1 Overview

This clause defines the `startFdCapture()` API.

Once the File Delivery Application Service registration is complete, the MBMS Aware Application can make calls on the `startFdCapture()` API to selected `fileURI`s for the files to be received through the MBMS service as shown in Figure 6.2.3.7.1-1.

![Figure 6.2.3.7.1-1: File Delivery Application Start Capture](image)

6.2.3.7.2 Parameters

The parameters for the `startFdCapture()` API are:

- **string serviceId** – see 6.2.3.4.2. The service ID for the service for which the files are captured.

- **string fileUri** – identifies the files to be captured on the service identified in `serviceId`. Allowed values include:
  - The empty string signals that the application is interested in receiving all new files and updates to previously received files.
  - A BaseURL, i.e., a complete path for subdirectory (a prefix) identifying a group of files under that directory.
  - An absoluteURL, i.e., a complete URL that identifies a single file resource.
- boolean disableFileCopy – when set to true, this signals that the application does not want the MBMS client to make the file available on the application space.

- boolean captureOnce – when set to true, signals that the file requested via the fileURI (or a file matching a BaseURL in fileURI, or any file if the fileURI is empty) is to be captured only once.

6.2.3.7.3 Pre-Conditions

The application is registered with the MBMS client to consume File Delivery Application Services.

The fileURI format is not validated by the MBMS client.

6.2.3.7.4 Usage of Method for Application

The MBMS Aware Application can make calls on the startFdCapture() API to the select file URIs for the files to be received through the MBMS service with service ID serviceId. It is recommended that http:// or file system names c:/user/… be used as file URIs.

An application may set the fileURI parameter to different values:

- An empty string signals that the application is interested in receiving all new files and updates to previously received files.

- If the fileURI is set to a Base URL as defined in RFC 3986 [11], the application may organize its files in a structured way (in a directory) such as to allow the identification of a group of files. For instance, a headline news clips application may group files under a …\sports\, a …\politics\, etc. folder and allow the user to select what type of headline news of interest and therefore request the MBMS client to capture all the files under …\sports\ if the user is only interested in sports headline news.

- An absolute URL, i.e., a complete URL that identifies a single file resource. A software update application on a given OEM device model may be preconfigured with an absolute URL for the file name that identifies the software image for that device model. That application would use that absolute URL as the file URI when request that its software image be received on a File Delivery Application Service.

The application should avoid overlap requests, e.g. requesting a fileURI and at the same time the Base URL that matches the fileURI.

The application may use the getFdActiveServices() API as defined in clause 6.2.3.14 to get back in synch with fileURI in remaining outstanding startFdCapture() requests.

When application is no longer interested in capturing specific files, it should call the stopFdCapture() interface as defined in clause 6.2.3.13.

A software update application on a given OEM device model may be preconfigured with an absolute URL for the file name that identifies the software image for that device model. That application would use that absolute URL as the file URI when request that its software image be received on a File Delivery Application Service.

6.2.3.7.5 Expected MBMS Client Actions

When this method is received, the MBMS client updates the internal parameters. For more details see clause 6.2.2.4.

6.2.3.7.6 Post-Conditions

The MBMS client is in CAPTURE_NOTIFY state for the requested serviceID.

The parameters of the MBMS client are updated.

After capturing the files requested on a startFdCapture() request, the MBMS Client prepares to send fileAvailable() notification as defined via the registered callback listener.
6.2.3.8 File Available Notification

6.2.3.8.1 Overview

This clause defines the fileAvailable() callback function.

As illustrated in Figure 6, once the MBMS client has successfully collected a file that matches an outstanding startFdCapture() request from an MBMS Aware Application, the MBMS client invokes the fileAvailable() callback function.

6.2.3.8.2 Parameters

The parameters for the fileAvailable() API are:

- string serviceId – definition see above.
- The following is the file information for the received file:
  - string fileUri – identifies the file captured on the service identified in serviceId.
  - string fileLocation – identifies the location where the MBMS Aware Application can find the collected file.
  - string contentType – indicates the MIME type for the file identified in the fileUri.
  - unsigned long availabilityDeadline – signals a deadline in seconds when the file stored at the fileLocation will be removed from the MBMS client storage location.

6.2.3.8.3 Pre-Conditions

The MBMS client is in CAPTURE_NOTIFY state for the serviceId.

The MBMS client has successfully received a file that is included in a _fileCaptureRequest[] record. Reception may be through broadcast only or may include unicast repair.

The MBMS client internal variable _locationPath may be defined or may not be defined.

The MBMS client has pre-configured an internal parameter defaultAvailabilityDeadline defining the time a file that is kept in the MBMS client owned storage location.

6.2.3.8.4 Expected MBMS Client Actions

The MBMS client invokes the fileAvailable() notification for each successfully received file that matches a _fileCaptureRequest[] and is included in the _fileURIStatus[] record. For more details see clause 6.2.2.5.

6.2.3.8.5 Usage of Method for Application

Once the application receives the callback, the application may access the file that is announced by the parameters in the callback function. If the storage is not defined by the locationPath application should access the file before the announced availabilityDeadline.

An MBMS Aware Application can retrieve the file using the HTTP GET method if the fileLocation is an HTTP URL.

The MBMS Aware Application needs to arrange for a copy of the file to the application space if the application intends to have access to the file beyond an availabilityDeadline indicated. The file may no longer be accessible after this time.
6.2.3.8.6 Post-Conditions

The file is available at the location defined by the fileLocation parameter.

6.2.3.9 File Delivery Application Service De-registration

6.2.3.9.1 Overview

This clause defines the deregisterFdApp() call.

An MBMS Aware Application registers services classes with the MBMS client to request the capture of files on File Delivery Application Services, but the application does not have to be currently registered while files are being captured as discussed earlier. The app may deregister using the deregisterFdApp() call.

6.2.3.9.2 Parameters

none

6.2.3.9.3 Pre-Conditions

The MBMS client is in REGISTERED or in CAPTURE_NOTIFY state for this application.

6.2.3.9.4 Usage of Method for Application

MBMS Aware Application registered with the MBMS client via the registerFdApp() API should invoke the deregisterFdApp() before exiting.

If the application deregisters, it will no longer receive notifications from the MBMS client. However, the MBMS client still captures files in the background until the registrationValidityDuration expires.

Nevertheless, the absence of notifications may result in unreceived files, if the MBMS client observes problems, e.g. not being able to access the storage location or the MBMS client having insufficient storage. Hence, the application should continuously check if the storage is still sufficient and accessible, even if is deregistered.

6.2.3.9.5 Expected MBMS Client Actions

The MBMS client no longer sends notifications.

If open file capture requests exist, the MBMS client continues collection files in the background until the time for _registrationValidityDuration expires.

For more details see clause 6.2.2.4.

6.2.3.9.6 Post-Conditions

The app is no longer registered with the MBMS client to receive notifications.

The MBMS client is either in IDLE mode or in CAPTURE_BACKGROUND mode.

6.2.3.10 File Download Failure Notification

6.2.3.10.1 Overview

This clause defines the fileDownloadFailure() callback function.
As illustrated in Figure 6.2.3.10.1-1, once the MBMS client has attempted to collect symbols for a file (possibly even via the unicast file repair procedure), that matches an outstanding startFdCapture() request from an MBMS Aware Application, the MBMS client may still not be able to recover the file. Once the MBMS client detects that it failed FEC decoding the file, the MBMS client invokes the fileDownloadFailure() callback function (which the application registered with the MBMS client).

**Figure 6.2.3.10.1-1: Signaling download failures**

6.2.3.10.2 Parameters

The parameters for the fileDownloadFailure() API are:

- string serviceId – identifies the File Delivery Application Service on.
- string fileUri – identifies the file which failed being received.

6.2.3.10.3 Pre-Conditions

The MBMS client is in CAPTURE_NOTIFY state for the serviceId.

6.2.3.10.4 Expected MBMS Client Actions

The MBMS client provides the fileAvailable() function for each non-successfully received file that matches a _fileCaptureRequest[] and is included in the _fileURIStatus[] record.

6.2.3.10.5 Usage of Method for Application

The application may use this information to identify other ways to access the file, or initiate actions to operate without this file.

6.2.3.10.6 Post-Conditions

The MBMS client may remain in CAPTURE_NOTICE state or if this was the last outstanding capture request it may move to REGISTERED state for the serviceId.
6.2.3.11 File List Available Notification

6.2.3.11.1 Overview

This clause defines the `fileListAvailable()` callback function.

As illustrated in figure 6, an MBMS Aware Application that is registered when a requested file is successfully received is notified of the availability of the new file via the `fileAvailable()` API.

Figure 6.2.3.11.1-1 illustrates what happens when an application registers to consume File Delivery Application Services with a non-zero `registrationValidityDuration`, asks different files to be captured (possibly from different File Delivery Application Services), and then de-registers.

During the registration validity duration period following the application de-registration, the MBMS client collects files matching the outstanding capture requests from the application and keeps the files in its cache while the application is not currently registered.

![Sequence diagram for notifying the application about collected files](image)

6.2.3.11.2 Parameters

The parameters for the `fileListAvailable()` API are:

- `string serviceId` - identifies the File Delivery Application service.

6.2.3.11.3 Pre-Conditions

The MBMS client is in `CAPTURE_NOTIFY` mode.

The MBMS client does have an `_fileURIStatus[]` entry for which the `_notified` flag is set to false.
6.2.3.11.4 Expected MBMS Client Actions

The MBMS client invokes the `fileListAvailable()` notification with the following parameters:

- The `serviceId` is set to the `_serviceID`.

6.2.3.11.5 Usage of Method for Application

The application receiving this notification may then ask the client on the status of the file list using the `getFdDownloadStateList()` method defined in clause 6.2.3.16.

6.2.3.11.6 Post-Conditions

No state change is involved.

6.2.3.12 Getting the List of Available Files

6.2.3.12.1 Overview

This clause defines the `getFdAvailableFileList()` request.

As illustrated in Figure 6.2.3.12.1-1, once the MBMS Aware Application re-registers with the MBMS client, the MBMS client may indicate through the `fileListAvailable()` callback function to the application know that a list of files have been received for a service and are now ready to be accessed.

That application can then invoke the `getFdAvailableFileList()` API to retrieve information on these received files.

6.2.3.12.2 Parameters

The parameters for the `getFdAvailableFileList()` API are:

- Input parameters:
  - `string serviceId` – identifies the File Delivery Application Service on for which the application requests the available file list.

- Output parameters
  - A list for records, each containing:
    - `string fileUri` – identifies the file captured on the service identified in `serviceId`.
    - `string fileLocation` – identifies the location where the MBMS Aware Application can find the collected file.
    - `string contentType` – indicates the MIME type for the file identified in the `fileUri`.
    - `unsigned long availabilityDeadline` – signals a deadline in seconds when the file stored at the `fileLocation` will be removed from the MBMS client storage location, if applicable.

6.2.3.12.3 Pre-Conditions

The MBMS client is in `CAPTURE_NOTIFY` state for the `serviceId`.

The MBMS client has indicated through the `fileListAvailable()` callback function to the application know that a list of files have been received for a service and are ready to be accessed.

The MBMS client has pre-configured an internal parameter `defaultAvailabilityDeadline` defining the time a file that is kept in the MBMS client owned storage location.
6.2.3.12.4 Usage of Method for Application

The application may use this method in order to retrieve information on the received files.

Once the application receives the response, the application may access the files that are announced by the parameters in the callback function. If the storage is not defined by the locationPath the application should access the file before the announced availabilityDeadline.

6.2.3.12.5 Expected MBMS Client Operation

When this method is invoked, the MBMS client provides the file parameters as defined above.

6.2.3.12.6 Post-Conditions

The MBMS client has notified the application about all accessible files.

6.2.3.13 Stop File Delivery Capture

6.2.3.13.1 Overview

This clause defines the stopFdCapture() request.

The application can make startFdCapture() calls to define fileURIs for the files to be received within an MBMS Service. The application may use the use the stopFdCapture() request to undo such a call and stop capturing such requested files. This is shown in Figure 6.2.3.13.1-1.

![Figure 6.2.3.13.1-1: File Delivery Application Stop Capture](image)

6.2.3.13.2 Parameters

The parameters for the stopFdCapture() API are identical to the parameters for startFdCapture() as defined in clause 6.2.3.7.2.

6.2.3.13.3 Pre-Conditions

The MBMS client is in CAPTURE_NOTIFY state.
6.2.3.13.4 Usage of Method for Application

The application may use this request to undo such a call and stop capturing such requested files.

The application should cache the requested fileURIs and use the stopFdCapture() API to signal to the MBMS client when the application no longer wishes to receive files matching the fileURIs on earlier capture requests.

If the MBMS Aware application has not properly cached the list of fileURIs on its outstanding startFdCapture() requests, the application should invoke the getFdActiveServices() API described in clause 6.2.3.4 to resynchronize on its outstanding startFdCapture() requests.

6.2.3.13.5 Expected MBMS Client Actions

Upon receiving a stopFdCapture() the MBMS client updates its internal parameters and sends notifications, if applicable.

6.2.3.13.6 Post-Conditions

Entries in the _fileCaptureRequest[] record may be removed. If by this action the _fileCaptureRequest[] gets empty, the MBMS client changes to REGISTERED state.

6.2.3.14 Getting the list of outstanding fileURIs being captured

6.2.3.14.1 Overview

This clause defines the getFdActiveServices() request.

Figure 6.2.3.14.1-1 illustrates that the application may also invoke the getFdActiveServices() API to retrieve the fileURI for outstanding startFdCapture() requests.
6.2.3.14.2 Parameters

The parameters for the `getFdAvailableFileList()` API are:

- **Input parameters:**
  - `string serviceId` – identifies the File Delivery Application Service on for which the application requests outstanding `startFdCapture()` requests.

- **Output parameters:**
  - A list for records, each containing:
    - `string fileUri` – as defined in clause 6.2.3.7.2.

6.2.3.14.3 Pre-Conditions

The MBMS client is in **CAPTURE_NOTIFY** state.

6.2.3.14.4 Usage of Method for Application

The application may also invoke the `getFdActiveServices()` API to retrieve the `fileURI` for outstanding `startFdCapture()` requests.

It is recommended that especially after a new registration or once a more recent `startFdCapture()` with a `BaseURL` superseded an earlier `startFdCapture()` with an `AbsoluteURL`.

6.2.3.14.5 MBMS Client Actions

When this method is invoked, the MBMS client provides the parameters in the call.

6.2.3.14.6 Post-Conditions

This call does not change any state or internal parameters of the MBMS client.

6.2.3.15 Notification on state change for files

6.2.3.15.1 Overview

This clause defines the `fileDownloadStateUpdate()` callback function.

As illustrated in Figure 6.2.3.15.1-1, after an MBMS Aware Application registers with the MBMS client and requests that files are to be captured, the MBMS client may issue `fileDownloadStateUpdate()` notifications to an application to signal that the state the MBMS client maintains for file(s) received or being received for the application has changed.
Figure 6.2.3.15.1-1: Sequence diagram for notifying the application about changes to the state of files being collected

6.2.3.15.2 Parameters

The parameters for the `fileDownloadStateUpdate()` callback function are:

- `string serviceId` – identifies the File Delivery Application Service on for which a new status is indicated.

6.2.3.15.3 Pre-Conditions

The MBMS client is in the `CAPTURE_NOTIFY` state.

6.2.3.15.4 Expected MBMS Client Actions

The MBMS client may invoke this method whenever the in the internal `_fileURIStatus[]` was changed.

6.2.3.15.5 Usage of Method for Application

If the application receives this callback notification, it should issue a `getFdDownloadStateList()`.

6.2.3.15.6 Post-Conditions

No state change is happening, but the application is aware that it can receive updated information from the MBMS client.

6.2.3.16 Getting the state on file(s) received or being received

6.2.3.16.1 Overview

This clause defines the `getFdDownloadStateList()` request function.

An MBMS Aware application may be interested to retrieve the current state for files downloaded or being downloaded by the MBMS client on behalf of that application. The application may choose to request this information in response to a notification from the MBMS client of such state change via a `fileDownloadStateUpdate()` notification, but also in other cases.
6.2.3.16.2 Parameters

The parameters for the `getFdDownloadStateList()` API are:

- **Input parameters:**
  - string `serviceId` - identifies the File Delivery Application Service on for which the application requests the available file list.

- **Output parameters:**
  - A list for records, each containing:
    - string `fileUri` - identifies the file captured on the service identified in `serviceId`.
    - `DownloadState state` - state of the file identified by the `fileUri`. The value can be as follows:
      - FD_REQUESTED - capture is requested, but file is neither scheduled nor is reception in process. This may for example be the case if the reception has failed, so the capture request stays open.
      - FD_SCHEDULED - scheduled, if a file schedule is delivered and a file is scheduled, but not yet received.
      - FD_IN_PROGRESS - the reception of the file is in progress.

6.2.3.16.3 Pre-Conditions

The MBMS client is in CAPTURE_NOTIFY state.

6.2.3.16.4 Usage of Method for Application

An MBMS Aware application may be interested to retrieve the current state for files downloaded or being downloaded by the MBMS client on behalf of that application. The application may choose to request this information in response to a notification from the MBMS client of such state change via a `fileDownloadStateUpdate()` notification.

The application may also detect via updated service definition information (i.e., via a `fdServiceListUpdate()` followed by a `getFdServices()`)) that a file previously advertised on an earlier `getFdServices()` and which the application requested to be capture is no longer described on the information retrieved via the latest `getFdServices()`, and the application did not receive a `fileAvailable()` or a `fileDownloadFailure()` reporting the successful or failed reception of the requested file, respectively. This could happen because the requested file is no longer advertised as available for request (there is no current of future transmission for the file described on a fileSchedule in the scheduled description fragment), but the file is still pending file repair.

An interested application can request information on the current state for files requested to be downloaded by the MBMS client on behalf of that application by invoking the `getFdDownloadStateList()` API.

6.2.3.16.5 Expected MBMS Client Actions

When this API call is received, the MBMS client provides the state of all files for which a capture request is issued.

6.2.3.16.6 Post-Conditions

There is no state change involved in the client.

6.2.3.17 Notification of updates to the service definition

6.2.3.17.1 Overview

This clause defines the `fdServiceListUpdate()` callback function.

As illustrated in Figure 6.2.3.15.1-1, after an MBMS Aware Application registers with the MBMS client and possibly requests that files are to be captured, the MBMS client may issue `fdServiceListUpdate()` notifications to an
application to signal that there have been changes to the definition of File Delivery Application Services associated with the service classes the application has registered with the MBMS client.

6.2.3.17.2 Parameters

none

6.2.3.17.3 Pre-Conditions

The MBMS client is in REGISTERED or CAPTURE_NOTIFY mode.

6.2.3.17.4 Expected MBMS Client Operation

The MBMS client invokes this notification when there has been a change to the parameters reported to the application in response to a getFdServices() API.

6.2.3.17.5 Usage of Method for Application

In response to a fdServiceListUpdate() API notification from the MBMS client, the MBMS Aware application should invoke a getFdServices() API and process the updated information accordingly.

6.2.3.17.6 Post-Conditions

There is no change in the client state.

6.2.3.18 Notification of File Delivery Application Service errors

6.2.3.18.1 Overview

This clause defines the fdServiceError() callback function.

As illustrated in Figure 6.2.3.18.1-1, the startFdCapture() request from an MBMS Aware Application may not be served, so the MBMS client will send a failure indication via the fdServiceError() to signal the error code for the result of processing the application's startFdCapture().

Figure 6.2.3.18.1-2 also illustrates that the fdServiceError() is used to signal the error code for the result of processing the application's stopFdCapture() request.

![Diagram showing signaling errors with the startFdCapture() request from the MBMS Aware Application](diagram.png)
6.2.3.18.2 Parameters

The parameters for the `fdServiceError()` callback are:

- string `serviceId` – identifies the File Delivery Application service for which this notification applies.
- `FdErrorCode` `errorCode` – identifies the error code for the reason causing the `startFdCapture()` or the `stopFdCapture()` request for the `serviceId` and `fileUri` to fail. The available error codes are:
  - `FD_INVALID_SERVICE` – signals that `serviceID` defined on the `startFdCapture()` or the `stopFdCapture()` request is not currently defined or it is not associated with the service classes with the MBMS Aware Application is registered.
  - `FD_DUPLICATE_FILE_URI` – signals that `fileUri` defined on the `startFdCapture()` request has already been requested on a previous `startFdCapture()` request. This is a duplicate request and the previous request is still in effect, i.e., impact to that earlier request. The MBMS client will not signal this error for the same condition on a `stopFdCapture()` request.
  - `FD_AMBIGUOUS_FILE_URI` – signals that `fileUri` defined on the `startFdCapture()` or the `stopFdCapture()` request creates ambiguity with a previously issued `startFdCapture()` or `stopFdCapture()` request. See clauses 6.2.3.7 and 6.2.3.13 for details on the conditions when this error code is generated for the `startFdCapture()` and the `stopFdCapture()` request, respectively.
  - `FD_STOP_FILE_URI_NOT_FOUND` – signals that the indicated `fileURI` does not match an outstanding `startFdCapture()` request.
  - `FD_UNKNOWN_ERROR` – signals an error condition not explicitly identified.
- string `errorMsg` – may provide additional textual description of the error condition.

6.2.3.18.3 Pre-Conditions

The MBMS client is in `REGISTERED` or `CAPTURE_NOTIFY` mode.

6.2.3.18.4 Expected MBMS Client Actions

If a `startFdCapture()` or a `stopFdCapture()` request from an MBMS Aware Application may not be served, the MBMS client will send a failure indication via the `fdServiceError()` to signal the error code for the result of processing.
6.2.3.18.5  Usage of Method for Application

If the application receives such a notification, it should check the capture requests and possibly also invoke the getFdActiveServices() API call to re-synchronize on its outstanding startFdCapture() requests.

6.2.3.18.6  Post-Conditions

No state change applies.

6.2.3.19  Notification on storage limitations

6.2.3.19.1  Overview

This clause defines the insufficientStorage() callback function.

As illustrated in Figure 6.2.3.19.1-1, once a file is to be received for an MBMS Aware Application (at a scheduled transmission time for the respective File Delivery Application Service), the FDT for the FLUTE session for that service will signal the size for that file.

When the MBMS client detects that not enough storage is available on the UE to receive the file, the MBMS client will send the warning indication via the insufficientStorage() API to signal the application of the low storage condition. The application may be able to clean up some of its own files or alert the user to clean up storage space on the UE.

![Diagram of MBMS Aware Application and MBMS Client](image)

**Figure 6.2.3.19.1-1: Signaling a low storage level condition impacting a file download**

6.2.3.19.2  Parameters

The parameters for the insufficientStorage() callback are:

- **string serviceId** – identifies the File Delivery Application service for which this notification applies.

- **string fileUri** – identifies the file being transmitted on the File Delivery Application Service in serviceId which the MBMS client has started to capture and that will fail download because of insufficient storage on the UE.

- **StorageLocation locationPath** – identifies a local directory available on the device storage, which the application can access and where successfully collected files can be copied/moved before notifying that the file is available to the application. The storage location is a string pointing to a directory, or it may be empty, if no location is provided.
- unsigned long storageNeeded – indicates the additional storage space that needs to be cleared on the storage Path to enable the download of the file in fileURI to succeed.

- string errorMsg – may provide additional textual description of the error condition.

6.2.3.19.3 Pre-Conditions
The MBMS client is in CAPTURE_NOTIFY state.

6.2.3.19.4 Expected MBMS Client Actions
The insufficientStorage() API is invoked for the applications that are currently registered at the time that the low storage condition is detected.

6.2.3.19.5 Usage of Method for Application
If the MBMS-aware application receives such a notification, it should take appropriate measures to enable to continue the service. This may include to change the service location, clear some storage autonomously or to communicate with the user to release storage.

6.2.3.19.6 Post-Conditions
No state changes occur.

6.2.3.20 Notification on storage access issues

6.2.3.20.1 Overview
This clause defines the inaccessibleLocation() callback function.

As illustrated in Figure 6.2.3.20.1-1, the locationPath where the MBMS Aware Application registered to have its requested files copied may not be available (e.g., SD card not inserted/locked). When the MBMS client detects that the register locationPath is not accessible, the MBMS client will send the warning indication via the inaccessibleLocation() API to signal the application of the storage access limitation; this can be done at different times, e.g., following a startFdCapture() as illustrated in Figure 14. The application may select an alternative locationPath, or prompt the user to choose another locationPath. The application can notify the MBMS client of the new locationPath via the setFdStorageLocation() API.

![Diagram](image)

Figure 6.2.3.20.1-1: Signaling a storage access condition limitation impacting file download
6.2.3.20.2 Parameters

The parameters for the \texttt{inaccessibleLocation()} callback are:

- \texttt{string serviceId} – identifies the File Delivery Application service for which this notification applies.

- \texttt{StorageLocation locationPath} – indicates the storage location where files are to be stored per the registered locationPath at the time that the download started, which is not accessible by the MBMS client.

- \texttt{string errorMsg} – may provide additional textual description of the error condition.

6.2.3.20.3 Pre-Conditions

The MBMS client is in \texttt{CAPTURE\_NOTIFY} state.

6.2.3.20.4 Expected MBMS Client Actions

The \texttt{inaccessibleLocation()} API is only invoked for the applications that are currently registered at the time that the storage inaccessible condition is detected.

6.2.3.20.5 Usage of Method for Application

If the application receives this notification, the application should take appropriated measures. It may for example change the location or may alert the user that the storage is not accessible.

6.2.3.20.6 Post-Conditions

No state change is applied, but the MBMS client may fail to receive files.

6.2.3.21 Checking the version for File Delivery Application Service interface

6.2.3.21.1 Overview

This clause defines the \texttt{getVersion()} request function.

6.2.3.21.2 Parameters

The parameters for the \texttt{getVersion()} API call are:

- \texttt{string version} – identifies the version of the MBMS clients API implementation.

6.2.3.21.3 Pre-Conditions

The MBMS client may be in any state.

6.2.3.21.4 Operation of Method in MBMS Client

The \texttt{getVersion()} API returns the version of the implemented APIs of the MBMS client.

6.2.3.21.5 Usage of Method for Application

In order for the MBMS Aware Application to know the version of the File Delivery Application Service interface, the \texttt{getVersion()} API may be used. If the version number is not supported by the application, it should deregister and not use the API.

6.2.3.21.6 Post-Conditions

Note state change applies.
6.3 DASH Streaming Service API

6.3.1 Introduction

The DASH Streaming Service API provides MBMS Aware Applications with interfaces to manage the reception of DASH Media Presentations delivered over DASH-over-MBMS services that are built on the Download Delivery Method. This API is intended to support live DASH streaming applications.

The IDL for the DASH Streaming Service API is defined in Annex B.3.

6.3.2 MBMS Client State Model for DASH Streaming

6.3.2.1 Overview

Figure 6.3.2-1 provides an informative client state model in order to appropriately describe the messages on the DASH streaming service API. Four different states are defined. State changes may happen based on:

- Calls from the application or the DASH client
- Information provided by the MBMS User Service (USD, schedule, FDT, file complete)
- Changes in the reception conditions

![Figure 6.3.2-1: State Diagram]

Table 6.3.2-1 defines states for the MBMS client. Detailed descriptions are provided in the following subclauses.

<table>
<thead>
<tr>
<th>States and Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDLE</td>
<td>In this state the MBMS client does not have a registered application and it may not keep the service definition up to date. For more details see clause 6.3.2.3.</td>
</tr>
<tr>
<td>NON_AVAILABLE</td>
<td>In this state the MBMS client is not available and an application cannot register with the MBMS client.</td>
</tr>
</tbody>
</table>
States and Parameters | Definition
--- | ---
REGISTERED | In this state the MBMS client has registered the application, it may keep the service definition up to date, and it may be providing file capture services to the application(s). In this state the MBMS client sends callback notifications to the application. For more details see clause 6.3.2.4.
ACTIVE | In this state the MBMS client provides all services to of the REGISTERED state and also provides the streaming service to the application. For more details see clause 6.3.2.5.
STALLED | In this state the MBMS client provides all services to of the REGISTERED state, but the streaming services is at least temporarily stalled. For more details see clause 6.3.2.6.

6.3.2.2 MBMS Client Internal parameters

The MBMS client maintains internal parameters as defined in Table 6.3.2.2-1. Note that the parameters are conceptual and internal and only serve for the purpose to describe message generation on the API calls.

Table 6.3.2.2-1: Parameters of MBMS Client for DASH Streaming Service

<table>
<thead>
<tr>
<th>Internal Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_app[]</td>
<td>The MBMS client maintains a parameter set per registered app</td>
</tr>
<tr>
<td>_appId</td>
<td>A unique ID provided by the application and assigned to the app.</td>
</tr>
<tr>
<td>_serviceClass[]</td>
<td>A list of service classes identifying the services the application has access to.</td>
</tr>
<tr>
<td>_registrationValidityDuration</td>
<td>A period of time following the application de-registration over which the MBMS client continues to capture files for the application, see clause.</td>
</tr>
<tr>
<td>_service[]</td>
<td>The MBMS client maintains a parameter list per service. In this context the list is assigned also to one app, but an implementation may share the internal parameter list assigned to a service across multiple apps.</td>
</tr>
<tr>
<td>_serviceID</td>
<td>The service ID for a Streaming Application service over which the MBMS client collects files for the application.</td>
</tr>
<tr>
<td>_serviceClass</td>
<td>The service class associated with the Streaming Application service assigned the Service ID.</td>
</tr>
<tr>
<td>_serviceLanguage</td>
<td>The language of the service</td>
</tr>
<tr>
<td>_serviceName[]</td>
<td>The service name, possibly expressed in different languages.</td>
</tr>
<tr>
<td>_name</td>
<td></td>
</tr>
<tr>
<td>_lang</td>
<td></td>
</tr>
<tr>
<td>_serviceBroadcastAvailability</td>
<td>The service broadcast availability for the client. Three different types are defined: BROADCAST_AVAILABLE – UE is in broadcast coverage BROADCAST_UNAVAILABLE – UE is outside of broadcast coverage SERVICE_UNAVAILABLE – The service is unavailable for the UE</td>
</tr>
<tr>
<td>_MPD</td>
<td></td>
</tr>
<tr>
<td>_IS[]</td>
<td>The latest MPD associated to the service</td>
</tr>
<tr>
<td>_mpdURI</td>
<td>The Initialization Segments for the Media Presentation</td>
</tr>
<tr>
<td>_sessionSchedule[]</td>
<td>The URI which is provided to the application for initiating the DASH Media Presentation.</td>
</tr>
<tr>
<td>_start</td>
<td>Documents the session schedule for this session. Only sessionSchedule records should be included for which the value of the _stop time is in the future.</td>
</tr>
</tbody>
</table>
### Internal Parameters

<table>
<thead>
<tr>
<th>_stop</th>
</tr>
</thead>
</table>

### 6.3.2.3 MBMS Client Operation in IDLE state

The MBMS client may listen to the User Service Bundle Description and may collect information. However, no binding with the application is in place.

When the `registerStreamingApp()` as defined in subclauses 6.3.3.2 and 6.3.3.26.3.2 is invoked, then:

1. The MBMS client checks the input parameters for consistency and sets the internal variables:
   a) If the functions of the MBMS client is not accessible, the MBMS client throws a `FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE` result code in the `registerStreamingResponse()` as defined in subclause 6.3.3.3 and abort the following steps and may at least temporarily move in `NOT_AVAILABLE` state.
   b) If `appId` is an empty string then the MBMS client throws a `MISSING_PARAMETER` result code in the `registerStreamingResponse()` as defined in subclause 6.3.3.3 and abort the following steps and stays in IDLE mode. If not, the MBMS client sets the internal variable `_appId` to the value of the parameter.
   c) The MBMS client adds each entry in the `serviceClassList` parameter to its `_serviceClass[]` record. Note that the `serviceClassList` parameter may contain an empty service class entry. If an empty service class is provided the MBMS client considers the application to be registered with a service class that is also empty and only allow the application to have access to DASH Streaming Application Services that are not associated with a `serviceClass` (i.e., the USD for these services do not have a `serviceClass` defined).
   d) On receiving a `registerStreamingApp()` following a `deregisterStreamingApp()`, the MBMS client updates the `serviceClassList` to its `_serviceClass[]` record in the same way described for the `setStreamingServiceClassFilter()` method.
   e) If `callBack` is defined, the MBMS client uses the interfaces in the callback parameter of the `registerStreamingApp()` interface to send notification of event occurrences to the Application.

2. generates a response `registerStreamingResponse()` as defined in subclause 6.3.3.3 and changes to `REGISTERED` state as defined in clause 6.3.2.4:
   a) If the MBMS client functions cannot be activated for any reason, especially if the Streaming Delivery Application Service API did not find an MBMS client available on the UE on which the application is running, the `FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE` registration response code is sent. The MBMS client may provide a message.
   b) If the application did not provide a mandatory parameter the MBMS client functions cannot be activated, the `MISSING_PARAMETER` registration response code is sent.
   c) If the MBMS client functions can be activated, then:
      i) the `RegResponseCode` is set to `REGISTER_SUCCESS` registration response code;
      ii) a message may be generated.
   d) Sends the response with the above parameters.

3. If the MBMS client functions can be activated and the response is sent with a `REGISTER_SUCCESS`, then MBMS client is in `REGISTERED` state and uses the `REGISTERED` parameters to provide the list of matching streaming delivery services using the information in the User Service Description (USD). If the response is sent with a `FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE`, then MBMS client is in `NOT_AVAILABLE` state. If the response is sent with a `MISSING_PARAMETER`, then MBMS client is in IDLE state.
If the MBMS client receives the `getVersion()` API call as defined in clause 6.3.3.13, it shall return version 1.0.

### 6.3.2.4 MBMS Client Operation in REGISTERED state

For each registered app and the assigned parameters according to Table 6.3.2.2-1, the MBMS client uses the information in the User Service Description as well as its internal state information for the app in `_app[]` in the service class list `_serviceClass[]` to collect and keep up-to-date all internal information for the services of interest for the app, i.e. those that are member of any service class for which the application has interest.

For each MBMS user service for which the USD as defined in TS 26.346 [5] is available in the MBMS client for the service classes registered by the application in `_serviceClass[]` and which is identified as a DASH-over-MBMS service according to the definition in TS 26.346 [5], clause 5.6, one service record in the internal parameter `_service[]` is defined in the MBMS client and continuously updated whenever a new USD is available:

- For each `userServiceDescription.name` element, a `(name, lang)` pair is generated and added to the `_serviceName[]` list with `name` set to the value of the USD element, and if present, the `lang` set to the value of the associated `@lang` attribute. If no `@lang` attribute is present, the `lang` parameter is set to an empty string.
- If the attribute `userServiceDescription.serviceClass` is present, the value of this attribute is assigned to `_serviceClass`. If not present, the `_serviceClass` is set to an empty string.
- The value of the attribute `userServiceDescription.serviceId` is assigned to `_serviceId`.
- If the attribute `userServiceDescription.serviceLanguage` is present, the value of this attribute is assigned to `_serviceLanguage`. If not present, the `_serviceLanguage` is set to an empty string.
- The MPD metadata fragment referenced by either the `r9:mediaPresentationDescription` element or by an a `r12:appService` referencing an MPD and conforming to TS 26.247 [7] is extracted by the MBMS client. The contained MPD is stored in the `_MPD` parameter and the Initialization Segments are stored in the `_IS[]`. The `_mpdURI` parameter is generated at which location the MPD will be made available.
- The `_serviceBroadcastAvailability` is continuously updated set it to `BROADCAST_AVAILABLE`, if broadcast is available (if the UE is in broadcast coverage of the service), if not, it is set to `BROADCAST_UNAVAILABLE` (if the UE is NOT in broadcast coverage of the service).
- If the `userServiceDescription.schedule` element is present then the MBMS client uses the information in the schedule description fragment to generate the internal `_sessionSchedule[]` list and keep up to date as a result of USD updates. The MBMS client shall only include `_sessionSchedule[]` records if the `_stop` value is in the future.

If updates are provided and added to the `_service[]` parameter, the MBMS client should send a `streamingServiceListUpdate()` callback as defined in clause 6.3.3.6.

When the `getStreamingServices()` method is received as defined in clause 6.3.3.4, the MBMS client sets the parameters as follows:

- If the `_service[]` list is empty, the list is empty.
- For each MBMS user service in the `_service[]` list, one service record is generated as follows:
  - The value of the attribute `_serviceId` is assigned to `serviceId`.
  - The value of the attribute `_serviceClass` is assigned to `serviceClass`.
  - The value of `_serviceLanguage` is assigned to `serviceLanguage`.
  - For each record in the `_serviceName[]` one `serviceNameList` entry is generated and:
    - the `name` is set to the value `_name`,
    - the `name` is set to the value `_name`,
- The value of _serviceBroadcastAvailability is assigned to serviceBroadcastAvailability.
- The _mpdURI is assigned to mpdURI.
- If at least one _sessionSchedule[] record is present then:
  - The activeDownloadPeriodStartTime is set to the value of earliest _start time of any entry in the _sessionSchedule[].
  - The activeDownloadPeriodStopTime is set to the value of the _stop time of the entry selected earliest start time.
- If no _sessionSchedule[] record is present:
  - The activeDownloadPeriodStartTime is set to 0.
  - The activeDownloadPeriodStopTime is set to 0.

When the setStreamingServiceClassFilter() as defined in clause 6.3.3.5 is received, the MBMS client runs the following steps:

- It replaces the internal variable _serviceClass[] with the parameter values provided in serviceClassList.
- The MBMS client dis-associates the service classes previously associated with the MBMS Aware Application that are not included on this list.
- The MBMS client associates the service classes not previously associated with the MBMS Aware Application that are newly included on this list.
- The MBMS client issues a streamingServiceListUpdate() notification as defined in clause 6.3.3.6 to the application to notify of this effect.

When the startStreamingService() method as defined in clause 6.3.3.7 is received with a parameter serviceID, the MBMS client runs the following steps:

- The MBMS client checks for errors and if necessary, the streamingServiceError() notification as defined in clause 6.3.3.12 is initiated. Specifically, if the MBMS client does not find a matching serviceId in its internal _service[] record, it responds with error code STREAMING_INVALID_SERVICE. Otherwise it may use the error code STREAMING_UNKNOWN_ERROR. An errorMsg may be provided in the errorMsg string.
- If the service with the serviceId parameter can be started:
  - The MBMS client uses the MPD in the _MPD parameter and the remaining associated metadata to offer a valid media presentation to the DASH client by providing a DASH server in the MBMS client. For different options to provide such a service, refer to clause 7.
  - The URL to the MPD that is exposed to the MBMS aware application for DASH consumption is stored in the internal variable _mpdURI. The MPD stored at this URI may be continuously updated, based on dynamic information received in the service announcement or inband MPD updates.
  - The MBMS client sends a serviceStarted() notification as defined in clause 6.3.3.8 with the serviceId being passed along with the notification.
  - The MBMS client moves to ACTIVE state as defined in clause 6.3.2.5.

Whenever there has been a change to the parameters reported to the application in response to a getStreamingServices() API, i.e. in the internal service class list _serviceClass[] to add a new service record to the list or a change in one of the following internal parameters in the service record in the _serviceLanguage, _serviceName[],_serviceBroadcastAvailability, or updates to the _mpdURI the MBMS client notifies application with streamingServiceListUpdate() as defined in clause 6.3.3.6.
When the `deregisterStreamingApp()` is received, all internal parameters for the app are cleared and the client moves to IDLE state.

6.3.2.5 MBMS Client Operation in ACTIVE state

The MBMS client carries out all actions as in the REGISTERED state.

The MBMS client continuously downloads the DASH resources and makes them available as announced in the MPD. For different options to provide such a service, refer to clause 7. The URL to the MPD that is exposed to the MBMS aware application for DASH consumption is stored in the internal variable `_mpdURI`. The MPD stored at this URI may be continuously updated, based on dynamic information received in the service announcement or inband MPD updates.

When the MBMS client receives a `stopStreamingService()` request as defined in clause 6.3.2.5 that matches an active service.

- The MBMS client checks for errors and if necessary, the `streamingServiceError()` notification as defined in clause 6.3.3.12 is initiated. Specifically, if the MBMS client does not find a matching `serviceId` in its internal `_service[]` record, it responds with error code `STREAMING_INVALID_SERVICE`. Otherwise it may use the error code `STREAMING_UNKNOWN_ERROR`. An `errorMsg` may be provided in the `errorMsg` string.

- The MBMS client stops providing the DASH resources at its DASH server, i.e. at the location announced in the MPD referenced by the `_mpdURI`.

- The MBMS client moves to REGISTERED state as defined in clause 6.3.2.4.

When the MBMS client receives a `stopStreamingService()` request as defined in clause 6.3.2.5 that matches an active service, the MBMS client terminates the download of the resources of this download delivery session and no longer makes it available at the indicated resources in the MPD. The MBMS client transitions to REGISTERED state when the internal parameter `_serviceBroadcastAvailability` transitions to `BROADCAST_UNAVAILABLE`, and no alternative delivery method is defined, or if the service is no longer available for other reasons (e.g. frequency conflict), then the service is stalled. In this case the MBMS client:

- No longer makes available the resources in the announced locations by the `_mpdURI` and the references therein.

- Sends a `serviceStalled()` notification as defined in clause 6.3.3.11, along with one of the following reasons:
  - `RADIO_CONFLICT` – indicates a frequency conflict, namely the service requested to be started via a `startStreamingService()` cannot be started at this time since the MBMS client is actively receiving another service on a different frequency band.
  - `END_OF_SESSION` – indicates that playback has reached the end of the scheduled transmission for the service as described by the schedule description fragment for the service. This should indicate that the advertised `activeServicePeriodEndTime` time has been reached.
  - `OUT_OF_COVERAGE` – indicates a UE mobility event to an area where the service with `streamingSubtype` set to `STREAMING_BC_ONLY` is not available via broadcast.
  - `STALLED_UNKNOWN_REASON` – indicates that another unspecified condition caused the service interruption.
  - Transitions to the `STALLED` state as defined in clause 6.3.2.6.

6.3.2.6 MBMS Client Operation in STALLED state

The MBMS client carries out all actions as in the REGISTERED state.

In this state the MBMS client continuously monitors if the service can be made available again.
Once the service gets available again, the MBMS client:

- The MBMS client downloads the DASH resources and makes them available as announced in the MPD. For different options to provide such a service, refer to clause 7. The URL to the MPD that is exposed to the MBMS aware application for DASH consumption is stored in the internal variable\texttt{mpdURI}. The MPD stored at this URI may be continuously updated, based on dynamic information received in the service announcement or inband MPD updates.

- The MBMS client sends a \texttt{serviceStarted()} notification as defined in clause 6.3.3.8 with the \texttt{serviceId} being passed along with the notification.

- The MBMS client moves to \texttt{ACTIVE} state as defined in clause 6.3.2.5.

### 6.3.3 Methods

#### 6.3.3.1 Overview

Table 6.3.3.1-1 provides an overview over the methods defined for the Streaming Delivery Application Service API. Different types are differentiated, namely state changes triggered by the app, status query of the app to the client, parameter updates as well as notifications from the client. The direction of the main communication flow is provided.

<table>
<thead>
<tr>
<th>Method</th>

</tbody>
</table>

#### 6.3.3.2 Registration

#### 6.3.3.2.1 Overview

This clause defines \texttt{registerStreamingApp()} interface.
An MBMS Aware Application calls the registerStreamingApp() interface to register with the MBMS Client to consume streaming services. The registerStreamingApp() interface has two purposes:

1) It signals to the MBMS Client that an application is interested to consume MBMS DASH Streaming Services.

2) It allows the application to identify its callback listeners defined in the Streaming Service API for the MBMS Client to provide asynchronous notifications to the application on relevant events associated with streaming.

NOTE: Since some application development frameworks do not support callback functions, an MBMS Aware Application for these frameworks will not provide callback listeners in the registerStreamingApp() interface. Instead, the application will implement the necessary approach available on these frameworks to receive event notifications from the MBMS Client in place of callback functions. The notifications implemented on these frameworks will include the same information content as defined on the structures for the IDL callback functions.

Figure 6.3.3.2-1 shows the registration process.

![Figure 6.3.3.2-1: Application Registration sequence diagram](image)

### 6.3.3.2.2 Parameters

The parameters for the registerFdApp() API are:

- **string appId** – provides a unique ID for the application registering with the MBMS client, which uses this identity to maintain state information for a particular MBMS Aware Application. The uniqueness of the ID is in the context of any application that may possibly register with MBMS client. Uniqueness is typically provided on platform level.

- **any platformSpecificAppContext** – a platform-specific context for the registering application that enables the MBMS client to get extra information about the application that may be needed to enable the application to have access to MBMS services, e.g., to enable application authentication or to enable the application to communicate with the MBMS client via platform (e.g., HLOS) services.

- **sequence<string> serviceClassList** – provides a comma-separated list of service classes which the application is interested to register. Each service class string can be any string or it may be empty.

- **ILTEFileDeliveryServiceCallback callBack** – provides the MBMS client with the call back functions associated with DASH Streaming Application Service APIs for the registering MBMS Aware Application.
NOTE: The callback element in the IDL description is optional and only included when the application development framework supports programmatic callback interfaces. If callbacks are not supported on a given application development framework, the same information content as defined on the callback structures is to be provided to the application via the notification method available with that development framework when the respective condition is met.

6.3.3.2.3 Pre-Conditions

The application has assigned a unique application ID appId in the context of its operation (e.g., a smartphone HLOS) with the MBMS client.

The application is pre-configured with the set of service classes that allows it to consume the DASH Streaming Services associated with these service classes.

The application has access to a DASH Streaming client.

The application may use this method at launch or after a deregisterStreamingApp() has been called.

The MBMS client is in IDLE state.

6.3.3.2.4 Usage of Method for Application

The application uses the method registerStreamingApp() to register with the MBMS Client to consume Streaming Services.

The application provides its appId and, if applicable, some platform specific application context, platformSpecificAppContext.

The application provides the set of service classes which the application is interested to register.

6.3.3.2.5 Expected MBMS Client Actions

When this method is invoked, the MBMS client registers the app, if possible. For more details refer to clause 6.3.2.3.

6.3.3.2.6 Post-Conditions

The application expects the registerStreamingResponse() as defined in clause 6.3.3.3.

6.3.3.3 DASH Streaming Application Service Registration Response

6.3.3.3.1 Overview

This clause defines registerStreamingResponse() call.

As illustrated in Figure 6.3.3.2-1, the MBMS client responds to an Application call to the registerStreamingApp() API with a registerStreamingResponse() call back providing the result of the registration request.

6.3.3.3.2 Parameters

The parameters for the registerStreamingResponse() API are:

- EmbmsCommonTypes::RegResponseCode value – provides a result code on the registration request. The allowed values are:
  - REGISTER_SUCCESS – indicates that the registration has been processed successfully and the application can proceed with other API interactions with the MBMS client for Streaming Delivery Application Services.
  - FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE – Indicates that the registration has failed since the Streaming Delivery Application Service API did not find an MBMS client available on the UE on which the application is running and no MBMS service will be available to the application.
- **MISSING_PARAMETER** – indicates that the registration has failed since one or more of the required parameter was missing.
- **string message** – provides an associated text description of the error message. The message may be empty.

### 6.3.3.3 Pre-Conditions

The MBMS client has received a call via the `registerStreamingApp()` API as defined in clause 6.3.3.2.

### 6.3.3.4 Expected MBMS Client Actions

The MBMS client responds accordingly and depending on the response moves to one of the states: IDLE, NOT_AVAILABLE, or REGISTERED. For more details refer to clause 6.3.2.4.

### 6.3.3.5 Usage of Method for Application

Once the application receives a the `registerStreamingResponse()` with the `RegResponseCode` set to REGISTER_SUCCESS, the application can proceed with other API interactions with the MBMS client.

If the MBMS client is temporarily in NOT_AVAILABLE, if the `registerFdResponse()` signaled a failure with a FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE, the application may periodically recheck if the state of the MBMS client changes by retrying the `registerFdRequest()` API.

If the MBMS client is responding with MISSING_PARAMETERS, the application should fix the parameters and retry the `registerFdRequest()` API.

### 6.3.3.6 Post-Conditions

If the MBMS client functions cannot be activated and once the response is sent, then MBMS client is at least temporarily in NOT_AVAILABLE state.

If the MBMS client functions can be activated and respective response is sent, then MBMS client is in REGISTERED state with the REGISTERED parameters as set above.

### 6.3.3.4 Getting information on available DASH Streaming Application Services

#### 6.3.3.4.1 Overview

This clause defines `getStreamingServices()` API call.

The `registerStreamingApp()` interface returns the complete list of available Streaming Services information. As illustrated in Figure 6.3.3.2-1, after a successful registration with the MBMS client, the MBMS Aware Application can use the `getStreamingServices()` API to discover the available Streaming Services associated with the service classes registered via the `registerStreamingApp()`.

#### 6.3.3.4.2 Parameters

The `getStreamingServices()` API returns a list describing the available DASH Streaming Services, where each service is described by the following output only parameters:

- **sequence<ServiceNameLang> serviceNameList** – optionally provides a list of the service title name in possibly different languages. Each (name, lang) pair defines a title for the service on the language indicated.
- **string name** – offers a title for the user service on the language identified in the lang parameter.
- **string lang** – identifies a natural language identifier per RFC 3066 [10].
- **string serviceClass** – identifies the service class which is associated with the service.
- **string serviceId** – provides the unique service ID for the service. The uniqueness is among all services provided by the BMSC.

- **string serviceLanguage** – indicates the available language for the service and represented as an identifier per RFC 3066 [10].

- EmbmsCommonTypes::ServiceAvailabilityType serviceBroadcastAvailability – signals whether the UE is currently in the broadcast coverage area for the service.
  - The possible values are:
    - BROADCAST_AVAILABLE – if content for the service is broadcast at the current device location.
    - BROADCAST_UNAVAILABLE – if content for the service is not broadcast at the current device location.
    - SERVICE_UNAVAILABLE – if content for the service is at all available at the current device location.

- **string mpdUri** – provides an HTTP URL where the MPD for the DASH Streaming Application Service is hosted and available for DASH clients access.

- EmbmsCommonTypes::Date activeServicePeriodStartTime – signals the current/next active DASH Streaming Application Service start time, when DASH media segments and other resources start being broadcast over the air.

- EmbmsCommonTypes::Date activeServicePeriodEndTime – signals the current/next active DASH Streaming Application Service stop time, when DASH media segments and other resources stop being broadcast over the air.

### 6.3.3.4.3 Pre-Conditions

The MBMS client is in REGISTERED state.

### 6.3.3.4.4 Expected MBMS Client Actions

When this method is invoked, the MBMS client returns the streaming service parameters. For more details refer to clause 6.3.2.4.

### 6.3.3.4.5 Usage of Method for Application

The application should use this call right after the registerStreamingResponse() notification as defined in clause 6.3.3.3 is received or after the streamingServiceListUpdate() notification as defined in clause 6.3.3.6 is received.

The application should use the serviceId to identify the service in subsequent communication with the MBMS client to manage the streaming service.

The usage of the parameters serviceNameList, serviceClass, serviceBroadcastAvailability, and serviceLanguage is typically up to the application.

The mpdURI should be used by the application to initiate playback by initiating a DASH client. The application should assume that Media Presentation can be consumed by the DASH client without any further interaction with the MBMS-aware application.

The parameters activeServicePeriodStartTime and activeBroadcastPeriodEndTime provides the application the ability to determine the current broadcast state for the service as follows:

- If the current time is such that activeServicePeriodStartTime ≤ current time ≤ activeServicePeriodEndTime, DASH content is being broadcast for the service at the current time.
- If the `activeServicePeriodStartTime` is in the future, there is currently no broadcast being made for the service, but broadcast transmission is currently scheduled to start at this advertised time.

- If the `activeServicePeriodStartTime` is set to zero, there is no currently defined broadcast schedule time for the service.

6.3.3.4.6 Post-Conditions
This call does not change the MBMS client state.

The application uses the `serviceId` to identify the service in subsequent communication with the MBMS client.

6.3.3.5 Updating the registered service classes

6.3.3.5.1 Overview
This clause defines `setStreamingServiceClassFilter()` call.

While an application is actively registered with the MBMS client to consume DASH Streaming Services, the MBMS Aware Application can call the `setStreamingServiceClassFilter()` API to update the list of service classes the application wants to be registered with, see Figure 6.3.3.5.1-1.

![Figure 6.3.3.5.1-1: Sequence diagram for updating the registered service classes for an application](image)

6.3.3.5.2 Parameters
The parameters for the `setStreamingServiceClassFilter()` method are:

- `sequence<string> serviceClassList` – see clause 6.3.3.2.2

6.3.3.5.3 Pre-Conditions
The application is actively registered with the MBMS client to consume DASH Streaming Services, and MBMS client is in `REGISTERED` state for the application.
6.3.3.5.4 Expected MBMS Client Actions

When this method is invoked, the MBMS client updates the internal parameters and is expected to provide a `streamingServiceListUpdate()` notification as defined in clause 6.3.3.6. For more details refer to clause 6.3.2.4.

6.3.3.5.5 Usage of Method for Application

The MBMS Aware Application may invoke the `setStreamingServiceClassFilter()` API to update the previously defined new list of service classes that includes additional service classes or includes fewer service classes than the list of service classes.

The application should be aware that the updates are only active once an `streamingServiceListUpdate()` notification is received that confirms the new service class filters.

6.3.3.5.6 Post-Conditions

The MBMS-aware application expects a `streamingServiceListUpdate()` notification as defined in clause 6.3.3.6.

6.3.3.6 Updating the Streaming Service List

6.3.3.6.1 Overview

This clause defines `streamingServiceListUpdate()` notification.

This notification is used by the MBMS client to inform the application about a successful API call `setStreamingServiceClassFilter()` as shown in Figure 6.3.3.5.1-1 or other updates in streaming service list.

6.3.3.6.2 Parameters

None.

6.3.3.6.3 Pre-Conditions

The MBMS client is in `REGISTERED` state for the application. The MBMS-aware application has issued a `setStreamingServiceClassFilter()` API call.

6.3.3.6.4 Expected MBMS Client Actions

The MBMS client issues this notification as a response to a successful `setStreamingServiceClassFilter()` API call or to the response to updates of the service list provided in the MPD. For more details see clause 6.3.2.4.

6.3.3.6.5 Usage of Method for Application

The application is informed about the updates of the service class list and may issues a `getStreamingServices()` API call as defined in clause 6.3.3.4 to obtain the updated service list.

6.3.3.6.6 Post-Conditions

The MBMS-aware application has the latest service list. No state change is involved.
6.3.3.7 Start DASH Streaming Service

6.3.3.7.1 Overview

This clause defines `startStreamingService()` API.

After the DASH Streaming Application Service registration, the MBMS Aware Application can make calls on the `startStreamingService()` API for the MBMS client to start reception of DASH content received over unicast or broadcast as shown in Figure 6.3.3.7-1.

![Figure 6.3.3.7-1: Application starts DASH streaming services](image)

6.3.3.7.2 Parameters

The parameters for the `startStreamingService()` API are:

- `string serviceId` – see definition in clause 6.3.3.2.2.

6.3.3.7.3 Pre-Conditions

The MBMS client is in `REGISTERED` state.

The application has the latest service list, for example through the `getStreamingServices()` API call as defined in clause 6.3.3.4.

6.3.3.7.4 Usage of Method for Application

The MBMS Aware Application can make calls on the `startStreamingService()` API for the MBMS client to start reception of DASH content received over unicast or broadcast.

When application is no longer interested in consuming the Streaming Service, it should call the `stopStreaming()` API call as defined in clause 6.3.3.9.
6.3.3.7.5 MBMS Client Actions

When this method is invoked, the MBMS client starts the streaming service, if possible. For more details see clause 6.3.2.4.

6.3.3.7.6 Post-Conditions

The MBMS-aware application expects a `serviceStarted()` notification as defined in clause 6.3.3.8 or an appropriate error message.

6.3.3.8 Notification that DASH Streaming for a Service has started

6.3.3.8.1 Overview

This clause defines `serviceStarted()` callback function.

As illustrated in Figure 6.3.3.7-1, once the MBMS client has successfully collected all necessary information to start the service the MBMS client invokes the `serviceStarted()` callback function.

6.3.3.8.2 Parameters

The parameters for the `serviceStarted()` API are:

- `string serviceId` – see definition in clause 6.3.3.2.2.

6.3.3.8.3 Pre-Conditions

The MBMS application issued a `startStreamingService()` API call.

The MBMS client is in `REGISTERED` state for the `serviceId`.

6.3.3.8.4 Expected MBMS Client Actions

The MBMS client issues this notification if the service is started successful. For details see clause 6.3.2.4.

6.3.3.8.5 Usage of Method for Application

Once the application receives the callback on the successful start of the service with the `serviceId`, the application may start the streaming service by initiating a DASH Media Presentation at a DASH client by handing over the `mpdURI` received during the registration process for this service.

6.3.3.8.6 Post-Conditions

The DASH client can communicate with the MBMS client. The MBMS client makes available the DASH-over-MBMS service based on the MPD referenced in by the `mpdURI` of the service.

6.3.3.9 Stop DASH Streaming Service

6.3.3.9.1 Overview

This clause defines `stopStreamingService()` API.

As Figure 6.3.3.7-1 illustrates, when an MBMS Aware Application that issued a `startStreamingService()` for a service is no longer interested in consuming the DASH content for that service, it will call the `stopStreamingService()` API call.
6.3.3.9.2 Parameters
The parameter for the stopStreamingService() API is:

- string serviceId – see definition in clause 6.3.3.2.2.

6.3.3.9.3 Pre-Conditions
The MBMS client is in ACTIVE state for this application.

6.3.3.9.4 Usage of Method for Application
If an MBMS Aware Application is no longer interested in consuming the DASH service, it should call the stopStreamingService() API call. Latest at the same time, the Application should inform the DASH client about the termination of the service and the DASH client should no longer request resources that are provided directly or referenced by the mpdURI.

6.3.3.9.5 MBMS Client Actions
The MBMS terminates the reception. For more details see clause 6.3.2.5.

6.3.3.9.6 Post-Conditions
The MBMS client is in REGISTERED state. The Media Presentation referenced by the mpdURI can no longer be accessed as the referenced Segments will no longer be provided at the announced location in the MPD.

6.3.3.10 DASH Streaming Application Service De-registration

6.3.3.10.1 Overview
This clause defines deregisterStreamingApp() API call.

An MBMS Aware Application registers services classes with the MBMS client to request the start of streaming for DASH Streaming Application Services. The MBMS Aware Application that registered with the MBMS client via the registerStreamingApp() API should invoke the deregisterStreamingApp() before exiting. The MBMS clients stops monitoring for Service Announcement updates when there are no applications registered. There are no parameters for the registerStreamingApp() API.

6.3.3.10.2 Parameters
None.

6.3.3.10.3 Pre-Conditions
The MBMS client is in REGISTERED state for this application.

6.3.3.10.4 Usage of Method for Application
MBMS Aware Application registered with the MBMS client via the registerStreamingApp() API should invoke the deregisterStreamingApp() before exiting.

If the application deregisters, it will no longer receive notifications from the MBMS client and all context is cleared.

6.3.3.10.5 MBMS Client Actions
The MBMS client no longer sends notifications and clears all context for the Application.

6.3.3.10.6 Post-Conditions
The app is no longer registered with the MBMS client.
The MBMS client is in IDLE mode.

6.3.3.11 Notification that DASH Streaming for a Service has stalled

6.3.3.11.1 Overview

This clause defines the serviceStalled() notification.

The MBMS client enables consumption of a DASH Streaming Application Service if the current setting for serviceBroadcastAvailability is BROADCAST_AVAILABLE or BROADCAST_UNAVAILABLE. However, due to UE mobility in and out of broadcast coverage for some DASH Streaming Application Services, the serviceBroadcastAvailability for those services may change to SERVICE_UNAVAILABLE (i.e., the UE moves out of coverage for that service). Other circumstances may also prevent the broadcast reception of that service (e.g., a frequency conflict). In these circumstances, the MBMS client can signal the application that the service is temporarily not available for playback by invoking the serviceStalled() API.

When broadcast reception of the service is re-established, the MBMS client will signal the application that the service is again available for playback by invoking the serviceStarted() API. This is illustrated in Figure 6.3.3.11.1.

![Diagram](image)

**Figure 6.3.3.11.1: Signaling that a DASH streaming service stalled**

6.3.3.11.2 Parameters

The parameter for the serviceStalled() API are:

- string serviceId – identifies the DASH Streaming Application Service for which broadcast receptions have temporarily stalled.

- StalledReasonCode reason – provides specific information on what caused the service to stall. Valid options are:
- **RADIO_CONFLICT** – indicates a frequency conflict, namely the service requested to be started via a `startStreamingService()` cannot be started at this time since the MBMS client is actively receiving another service on a different frequency band.

- **END_OF_SESSION** – indicates that playback has reached the end of the scheduled transmission for the service as described by the schedule description fragment for the service. This should indicate that the advertised activeServicePeriodEndTime time has been reached.

- **OUT_OF_COVERAGE** – indicates a UE mobility event to an area where the service with streamingSubtype set to `STREAMING_BC_ONLY` is not available via broadcast.

- **STALLED_UNKNOWN_REASON** – indicates that another unspecified condition caused the service interruption.

### 6.3.3.11 Pre-Conditions

The MBMS client is in **ACTIVE** mode.

### 6.3.3.11.4 Expected MBMS Client Actions

The MBMS client provides a `serviceStalled()` notification in case it can no longer provide the referenced resources in the Media Presentation provided with mpdURI. For more details refer to clause 6.3.2.5.

### 6.3.3.11.5 Usage of Method for Application

The MBMS Aware Application should stop the DASH client playback on reception of the `serviceStalled()` notification. However, unless the application is no longer interested in the content, it should not issue a `stopStreamingService()` call in order to allow the MBMS client from trying to collect DASH content once the download problem is resolved. The application should inform the user of the temporary service interruption.

If the DASH client maintains in **STALLED** state for too long, the application should stop the service by issuing a `stopStreamingService()`.

### 6.3.3.11.6 Post-Conditions

The MBMS client is in **STALLED** mode.

### 6.3.3.12 Notification of DASH Streaming Application Service errors

#### 6.3.3.12.1 Overview

This clause the `streamingServiceError()` notification.

As illustrated in Figure 6.3.3.12.1-1, the `startStreamingService()` request from an MBMS Aware Application may not be served, so the MBMS client will send a failure indication via the `streamingServiceError()` to signal the error code for the result of processing the application's `startStreamingService()`.
6.3.3.12.2 Parameters

The parameters for the `streamingServiceError()` API are:

- `string serviceId` – identifies the DASH Streaming Application Service on which the MBMS client failed.

- `StreamingErrorCode errorCode` – identifies the error code for the reason causing the `startStreamingService()` or the `stopStreamingService()` request for the serviceId to fail. The available error codes are:
- STREAMING_INVALID_SERVICE – signals that serviceID defined on the
  startStreamingService() or the stopStreamingService() request is not currently defined or
  it is not associated with the service classes with the MBMS Aware Application is registered.
- STREAMING_UNKNOWN_ERROR – signals an error condition not explicitly identified.
- string errorMsg – may provide additional textual description of the error condition.

6.3.3.12.3 Pre-Conditions
The MBMS client has received a the startStreamingService() or a stopStreamingService() request.

6.3.3.12.4 Expected MBMS Client Actions
The MBMS client will send a failure indication via the streamingServiceError() to signal the error code for
the result of processing the application. For more details refer to clause 6.3.2.4 and 6.3.2.5.

6.3.3.12.5 Usage of Method for Application
If the MBMS Aware application receives this notification, it should revalidate the capture call. The application should
also update the service list by issuing a getStreamingServices() as defined in clause 6.3.3.4.

6.3.3.12.6 Post-Conditions
No state change is applied.

6.3.3.13 Checking the version for DASH Streaming Application Service interface

6.3.3.13.1 Overview
This clause defines the getVersion() request function.

6.3.3.13.2 Parameters
The parameters for the getVersion() API call are:
- string version – identifies the version of the MBMS clients API implementation.

6.3.3.13.3 Pre-Conditions
The MBMS client may be in any state.

6.3.3.13.4 Usage of Method for Application
In order for the MBMS Aware Application to know the version of the DASH Streaming Delivery Application Service
interface, the getVersion() API may be used. If the version number is not supported by the application, it should
deregister and not use the API.

6.3.3.13.5 MBMS Client Actions
The getVersion() API returns the version of the implemented APIs of the MBMS client.

6.3.3.13.6 Post-Conditions
No state changes apply.
6.4 MBMS RTP streaming delivery Service API

6.4.1 Introduction

The MBMS RTP streaming delivery Service API provides MBMS Aware Applications with interfaces to manage the reception of RTP services delivered over MBMS RTP streaming delivery services that are built on the Download Delivery Method. This API is intended to support RTP streaming applications.

The IDL for the MBMS RTP streaming delivery Service API is defined in clause B.4.

6.4.2 MBMS Client State Model for RTP-over-MBMS

6.4.2.1 Overview

Figure 6.4.2.1-1 provides an informative client state model in order to appropriately describe the messages on the MBMS RTP streaming delivery service API. Four different states are defined as listed in Table 6.4.2.1-1. State changes may happen based on:

- Calls from the application or the RTP client
- Information provided by the MBMS User Service (USD, schedule, FDT, file complete)
- Changes in the reception conditions

![State Diagram](image)

**Figure 6.4.2.1-1: State Diagram**

Table 6.4.2.1-1 defines states for the MBMS client. Detailed descriptions are provided in the following subclauses.
Table 6.4.2.1-1: States of MBMS Client

<table>
<thead>
<tr>
<th>States and Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDLE</td>
<td>In this state the MBMS client does not have a registered application and it may not keep the service definition up to date. For more details see clause 6.4.2.3.</td>
</tr>
<tr>
<td>NON_AVAILABLE</td>
<td>In this state the MBMS client is not available and an application cannot register with the MBMS client.</td>
</tr>
<tr>
<td>REGISTERED</td>
<td>In this state the MBMS client has registered the application, it may keep the service definition up to date, and it may be providing file capture services to the application(s). In this state the MBMS client sends callback notifications to the application. For more details see clause 6.4.2.3.</td>
</tr>
<tr>
<td>ACTIVE</td>
<td>In this state the MBMS client provides all services to of the REGISTERED state and also provides the RTP service to the application. For more details see clause 6.4.2.4.</td>
</tr>
<tr>
<td>STALLED</td>
<td>In this state the MBMS client provides all services to of the REGISTERED state, but the RTP services is at least temporarily stalled. For more details see clause 6.4.2.5.</td>
</tr>
</tbody>
</table>

6.4.2.2 MBMS Client Internal parameters

The MBMS client maintains internal parameters as defined in Table 6.4.2.2-1. Note that the parameters are conceptual and internal and only serve for the purpose to describe message generation on the API calls.

Table 6.4.2.2-1: Parameters of MBMS Client for MBMS RTP streaming delivery Service

<table>
<thead>
<tr>
<th>Internal Parameters</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>_app[]</td>
<td>The MBMS client maintains a parameter set per registered app</td>
</tr>
<tr>
<td>_appId</td>
<td>A unique ID provided by the application and assigned to the app.</td>
</tr>
<tr>
<td>_serviceClass[]</td>
<td>A list of service classes identifying the services the application has access to.</td>
</tr>
<tr>
<td>_registrationValidityDuration</td>
<td>A period of time following the application de-registration over which the MBMS client continues to capture files for the application, see clause.</td>
</tr>
<tr>
<td>_service[]</td>
<td>The MBMS client maintains a parameter list per service. In this context the list is assigned also to one app, but an implementation may share the internal parameter list assigned to a service across multiple apps.</td>
</tr>
<tr>
<td>_serviceID</td>
<td>The service ID for a RTP Application service over which the MBMS client collects files for the application.</td>
</tr>
<tr>
<td>_serviceClass</td>
<td>The service class associated with the RTP Application service assigned the Service ID.</td>
</tr>
<tr>
<td>_serviceLanguage</td>
<td>The language of the service</td>
</tr>
<tr>
<td>_serviceName[]</td>
<td>The service name, possibly expressed in different languages.</td>
</tr>
<tr>
<td>_name</td>
<td></td>
</tr>
<tr>
<td>_lang</td>
<td></td>
</tr>
<tr>
<td>_serviceBroadcastAvailability</td>
<td>The service broadcast availability for the client. Three different types are defined: BROADCASTAVAILABLE – UE is in broadcast coverage BROADCASTUNAVAILBLE – UE is outside of broadcast coverage</td>
</tr>
<tr>
<td>Internal Parameters</td>
<td>Definition</td>
</tr>
<tr>
<td>----------------------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>_SDP</td>
<td>The latest SDP associated to the service</td>
</tr>
<tr>
<td></td>
<td>The network interface name from which the started MBMS RTP streaming delivery service can be received.</td>

<tr>
<td>_interfaceName</td>
<td></td>
</tr>
<tr>
<td>_sdpURI</td>
<td></td>
</tr>
<tr>
<td>_sessionSchedule[]</td>
<td>Documents the session schedule for this session. Only sessionSchedule records should be included for which the value of the _stop time is in the future.</td>
</tr>
<tr>
<td>_start</td>
<td></td>
</tr>
<tr>
<td>_stop</td>
<td></td>
</tr>
</tbody>
</table>

### 6.4.2.3 MBMS Client Operation in IDLE state

The MBMS client may listen to the User Service Bundle Description and may collect information. However, no binding with the application is in place.

When the registerRTPApp() is invoked, then

1. The MBMS client checks the input parameters for consistency and sets the internal variables:
   
   a) If the functions of the MBMS client is not accessible, the MBMS client throws a FAILED LTE EMBMS SERVICE UNAVAILABLE result code in the registerRTPResponse() as defined in subclause 6.4.3.3 and abort the following steps and may at least temporarily move in NOT AVAILABLE state.
   
   b) If appId is an empty string then the MBMS client throws a MISSING_PARAMETER result code in the registerRTPResponse() as defined in subclause 6.4.3.3 and abort the following steps and stays in IDLE mode. If not, the MBMS client sets the internal variable _appId to the value of the parameter.
   
   c) The MBMS client adds each entry in the serviceClassList parameter to its _serviceClass[] record. Note that the serviceClassList parameter may contain an empty service class entry. If an empty service class is provided the MBMS client considers the application to be registered with a service class that is also empty and only allow the application to have access to MBMS RTP streaming delivery Application Services that are not associated with a serviceClass (i.e., the USD for these services do not have a serviceClass defined).
   
   d) On receiving a registerRTPApp() following a deregisterRTPApp(), the MBMS client updates the serviceClassList to its _serviceClass[] record in the same way described for the setRTPServiceClassFilter() method.
   
   e) If callback is defined, the MBMS client uses the interfaces in the callback parameter of the registerRTPApp() interface to send notification of event occurrences to the Application.

2. generates a response registerRTPResponse() as defined in subclause 6.4.3.3 and changes to REGISTERED state as defined in clause 6.4.2.4:

   a) If the MBMS client functions cannot be activated for any reason, especially if the RTP Delivery Application Service API did not find an MBMS client available on the UE on which the application is running, the FAILED LTE EMBMS SERVICE UNAVAILABLE registration response code is sent. The MBMS client may provide a message.
   
   b) If the application did not provide a mandatory parameter the MBMS client functions cannot be activated, the MISSING_PARAMETER registration response code is sent.
   
   c) If the MBMS client functions can be activated, then:

      i) the RegResponseCode is set to REGISTER_SUCCESS registration response code;

      ii) a message may be generated.
d) Sends the response with the above parameters

3. If the MBMS client functions can be activated and the response is sent with a REGISTER_SUCCESS, then MBMS client is in REGISTERED state and uses the REGISTERED parameters to provide the list of matching RTP delivery services using the information in the User Service Description (USD). If the response is sent with a FAILED LTE_EMBMS_SERVICE_UNAVAILABLE, then MBMS client is in NOT_AVAILABLE state. If the response is sent with a MISSING_PARAMETER, then MBMS client is in IDLE state.

If the MBMS client receives the get

**6.4.2.4 MBMS Client Operation in REGISTERED state**

For each registered app and the assigned parameters according to Table 6.4.2.2-1, the MBMS client uses the information in the User Service Description as well as its internal state information for the app in _app[] in the service class list _serviceClass[] to collect and keep up-to-date all internal information for the services of interest for the app, i.e. those that are member of any service class for which the application has interest.

For each MBMS user service for which the USD as defined in TS 26.346 [5] is available in the MBMS client for the service classes registered by the application in _serviceClass[] and which is identified as a MBMS RTP streaming delivery service according to the definition in TS 26.346 [5], clause 8, one service record in the internal parameter _service[] is defined in the MBMS client and continuously updated whenever a new USD is available:

- For each _userServiceDescription.element, a (name, lang) pair is generated and added to the _serviceName[] list with.name set to the value of the USD element, and if present, the._lang set to the value of the associated @lang attribute. If no @lang attribute is present, the._lang parameter is set to an empty string.
- If the attribute _userServiceDescription.serviceClass is present, the value of this attribute is assigned to._serviceClass. If not present, the._serviceClass is set to an empty string.
- The value of the attribute _userServiceDescription.serviceId is assigned to._serviceId.
- If the attribute _userServiceDescription.serviceLanguage is present, the value of this attribute is assigned to._serviceLanguage. If not present, the._serviceLanguage is set to an empty string.
- The SDP metadata fragment referenced by either the r9:sessionDescription element referencing an SDP and conforming to TS 26.346 [5] is extracted by the MBMS client. The contained SDP is stored in the._SDP parameter. The._sdpURI parameter is generated at which location the SDP will be made available. The network interface name from which the RTP data are available is stored in the._interfaceName parameter
- The._serviceBroadcastAvailability is continuously updated set it to BROADCAST_AVAILABLE, if broadcast is available (if the UE is in broadcast coverage of the service), if not, it is set to BROADCAST_UNAVAILABLE (if the UE is NOT in broadcast coverage of the service).
- If the _userServiceDescription.schedule element is present then the MBMS client uses the information in the schedule description fragment to generate the internal._sessionSchedule[] list and keep up to date as a result of USD updates. The MBMS client shall only include._sessionSchedule[] records if the._stop value is in the future.

If updates are provided and added to the._service[] parameter, the MBMS client should send a rtpServiceListUpdate() callback as defined in clause 6.4.3.6.

When the getRTPServices() method is received as defined in clause 6.4.3.4, the MBMS client sets the parameters as follows:

- If the._service[] list is empty, the list is empty
- For each MBMS user service in the._service[] list, one service record is generated as follows:
- The value of the attribute._serviceId is assigned to serviceId.
- The value of the attribute \_serviceClass is assigned to serviceClass.
- The value of \_serviceLanguage is assigned to serviceLanguage.
- For each record in the \_serviceName[] one serviceNameList entry is generated and:
  - the name is set to the value \_name,
  - the name is set to the value \_name.
- The value of \_serviceBroadcastAvailability is assigned to serviceBroadcastAvailability.
- The \_sdpURI is assigned to spdURI.
- If at least one \_sessionSchedule[] record is present then
  - The activeServicePeriodStartTime is set to the value of earliest \_start time of any entry in the \_sessionSchedule[].
  - The activeServicePeriodStopTime is set to the value of the \_stop time of the entry selected earliest start time.
- If no \_sessionSchedule[] record is present:
  - The activeServicePeriodStartTime is set to 0.
  - The activeServicePeriodStopTime is set to 0.

When the setRTPServiceClassFilter() as defined in clause 6.4.3.5 is received, the MBMS client runs the following steps:
  - It replaces the internal variable \_serviceClass[] with the parameter values provided in serviceClassList.
  - The MBMS client dis-associates the service classes previously associated with the MBMS Aware Application that are not included on this list.
  - The MBMS client associates the service classes not previously associated with the MBMS Aware Application that are newly included on this list.
  - The MBMS client issues a rtpServiceListUpdate() notification as defined in clause 6.4.3.6 to the application to notify of this effect.

When the startRTPService() method as defined in clause 6.4.3.7 is received with a parameter serviceID, the MBMS client runs the following steps:
  - The MBMS client checks for errors and if necessary, the rtpServiceError() notification as defined in clause 6.4.3.12 is initiated. Specifically, if the MBMS client does not find a matching serviceId in its internal \_service[] record, it responds with error code RTP_INVALID_SERVICE. Otherwise it may use the error code RTP_UNKNOWN_ERROR. An errorMsg may be provided in the errorMsg string.
  - If the service with the serviceId parameter can be started:
    - The MBMS client uses the SDP in the \_SDP parameter and the remaining associated metadata to offer a valid media presentation to the RTP client by providing an RTP server in the MBMS client. For different options to provide such a service, refer to clause 7.
    - The URL to the SDP that is exposed to the MBMS aware application for RTP consumption is stored in the internal variable \_sdpURI. The SDP stored at this URI may be continuously updated, based on dynamic information received in the service announcement updates.
    - The MBMS client sends a serviceStarted() notification as defined in clause 6.4.3.7 with the serviceId being passed along with the notification.
Whenever there has been a change to the parameters reported to the application in response to a `getRTPServices()` API, i.e. in the internal service class list `_serviceClass[]` to add a new service record to the list or a change in one of the following internal parameters in the service record in the `_serviceName`, `_serviceLanguage`, `_serviceBroadcastAvailability`, or updates to the `_sdpURI` the MBMS client notifies application with `rtpServiceListUpdate()` as defined in clause 6.4.3.6.

When the `deregisterRTPApp()` is received, all internal parameters for the app are cleared and the client moves to IDLE state.

### 6.4.2.5 MBMS Client Operation in ACTIVE state

The MBMS client carries out all actions as in the REGISTERED state.

The MBMS client continuously downloads the RTP data and makes them available as announced in the SDP. For different options to provide such a service, refer to clause 7. The URL to the SDP that is exposed to the MBMS aware application for RTP consumption is stored in the internal variable `_sdpURI`. The SDP stored at this URI may be continuously updated, based on dynamic information received in the service announcement updates.

When the MBMS client receives a `stopRTPService()` request as defined in clause 6.4.3.9 that matches an active service.

- The MBMS client checks for errors and if necessary, the `rtpServiceError()` notification as defined in clause 6.4.3.12 is initiated. Specifically, if the MBMS client does not find a matching `serviceId` in its internal `_service[]` record, it responds with error code `RTP_INVALID_SERVICE`. Otherwise it may use the error code `RTP_UNKNOWN_ERROR`. An `errorMsg` may be provided in the `errorMsg` string.

- The MBMS client stops providing the RTP data at its RTP server, i.e. at the location announced in the SDP referenced by the `_sdpURI`.

- The MBMS client moves to REGISTERED state as defined in clause 6.4.2.4.

When the MBMS client receives a `stopRTPService()` request as defined in clause 6.4.3.12 that matches an active service, the MBMS client terminates the reception of the data of this RTP delivery session and no longer makes it available at the indicated resources in the SDP. The MBMS client transitions to REGISTERED state.

When the MBMS the internal parameter `_serviceBroadcastAvailability` transitions to `BROADCAST_UNAVAILABLE`, and no alternative delivery method is defined, or if the service is no longer available for other reasons (e.g. frequency conflict), then the service is stalled. In this case the MBMS client:

- No longer makes available the resources in the announced locations by the `_sdpURI` and the references therein,

- Sends a `serviceStalled()` notification as defined in clause 6.4.3.11, along with one of the following reasons:
  - `RADIO_CONFLICT` – indicates a frequency conflict, namely the service requested to be started via a `startRTPService()` cannot be started at this time since the MBMS client is actively receiving another service on a different frequency band.
  - `END_OF_SESSION` – indicates that playback has reached the end of the scheduled transmission for the service as described by the schedule description fragment for the service. This should indicate that the advertised `activeServicePeriodEndTime` time has been reached.
  - `OUT_OF_COVERAGE` – indicates a UE mobility event to an area where the service is not available via broadcast.
  - `STALLED_UNKNOWN_REASON` – indicates that another unspecified condition caused the service interruption.

- Transitions to the STALLED state as defined in clause 6.4.3.11.
6.4.2.6 MBMS Client Operation in STALLED state

The MBMS client carries out all actions as in the REGISTERED state.

In this state the MBMS client continuously monitors if the service can be made available again.

Once the service gets available again, the MBMS client

- The MBMS client receives the RTP data and makes them available as announced in the SDP. For different options to provide such a service, refer to clause 7. The URL to the SDP that is exposed to the MBMS aware application for RTP consumption is stored in the internal variable _sdpURI. The SDP stored at this URI may be continuously updated, based on dynamic information received in the service announcement updates.

- The MBMS client sends a serviceStarted() notification as defined in clause 6.4.3.7 with the serviceId being passed along with the notification.

- The MBMS client moves to ACTIVE state as defined in clause 6.4.2.5.

6.4.3 Methods

6.4.3.1 Overview

Table 6.4-2 provides an overview over the methods defined for the MBMS RTP streaming delivery Service API. Different types are differentiated, namely state changes triggered by the app, status query of the app to the client, parameter updates as well as notifications from the client. The direction of the main communication flow is provided.

6.4.3.2 Registration

6.4.3.2.1 Overview

This clause defines registerRTPApp() interface.

An MBMS Aware Application calls the registerRTPApp() interface to register with the MBMS Client to consume MBMS RTP streaming delivery services. The registerRTPApp() interface has two purposes:

- It signals to the MBMS Client that an application is interested to consume MBMS RTP streaming delivery Services.
- It allows the application to identify its callback listeners defined in the MBMS RTP streaming delivery service API for the MBMS Client to provide asynchronous notifications to the application on relevant events associated with RTP-over-MBMS.

Note: Since some application development frameworks do not support callback functions, an MBMS Aware Application for these frameworks will not provide callback listeners in the registerRTPApp() interface. Instead, the application will implement the necessary approach available on these frameworks to receive event notifications from the MBMS Client in place of callback functions. The notifications implemented on these frameworks will include the same information content as defined on the structures for the IDL callback functions.

Figure 6.4-2 shows the registration process.

![Figure 6.4-2 Application Registration sequence diagram](image)

6.4.3.2.2 Parameters

The parameters for the registerRTPApp() API are:

- **string appId** – provides a unique ID for the application registering with the MBMS client, which uses this identity to maintain state information for a particular MBMS Aware Application. The uniqueness of the ID is in the context of any application that may possibly register with MBMS client. Uniqueness is typically provided on platform level.

- **any platformSpecificAppContext** – a platform-specific context for the registering application that enables the MBMS client to get extra information about the application that may be need to enable the application to have access to MBMS services, e.g., to enable application authentication or to enable the application to communicate with the MBMS client via platform (e.g., HLOS) services.
- `sequence<string>` serviceClassList – provides a comma-separated list of service classes which the application is interested to register. Each service class string can be any string or it may be empty.

- `ILTERTPServiceCallback` callBack – provides the MBMS client with the call back functions associated with MBMS RTP streaming delivery Service APIs for the registering MBMS Aware Application.

**NOTE:** The callback element in the IDL description is optional and only included when the application development framework supports programmatic callback interfaces. If callbacks are not supported on a given application development framework, the same information content as defined on the callback structures is to be provided to the application via the notification method available with that development framework when the respective condition is met.

### 6.4.3.2.3 Pre-Conditions

The application has assigned a unique application ID `appId` in the context of its operation (e.g., a smartphone HLOS) with the MBMS client.

The application is pre-configured with the set of service classes that allows it to consume the MBMS RTP streaming delivery Services associated with these service classes.

The application has access to a RTP client.

The application may use this method at launch or after a `deregisterRTPApp()` has been called.

The MBMS client is in IDLE state.

### 6.4.3.2.4 Usage of Method for Application

The application uses the method `registerRTPApp()` to register with the MBMS Client to consume MBMS RTP streaming delivery Services.

The application provides its `appId` and, if applicable, some platform specific application context, `platformSpecificAppContext`.

The application provides the set of service classes which the application is interested to register.

### 6.4.3.2.5 Expected MBMS Client Actions

When this method is invoked, the MBMS registers the app, if possible. For more details refer to clause 6.4.2.3.

### 6.4.3.2.6 Post-Conditions

The application expects the `registerRTPResponse()` as defined in 6.4.3.3.

### 6.4.3.3 MBMS RTP streaming delivery Service Registration Response

#### 6.4.3.3.1 Overview

This clause defines `registerRTPResponse()` call.

As illustrated in Figure 6.4-2, the MBMS client responds to an Application call to the `registerRTPApp()` API with a `registerRTPResponse()` call back providing the result of the registration request.

#### 6.4.3.3.2 Parameters

The parameters for the `registerRTPResponse()` API are:

- `EmbsCommonTypes::RegResponseCode` value – provides a result code on the registration request. The allowed values are:
- **REGISTER_SUCCESS** – indicates that the registration has been processed successfully and the application can proceed with other API interactions with the MBMS client for MBMS RTP streaming delivery Services.

- **FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE** – Indicates that the registration has failed since the MBMS RTP streaming delivery Service API did not find an MBMS client available on the UE on which the application is running and no MBMS service will be available to the application.

- **MISSING_PARAMETER** – indicates that the registration has failed since one or more of the required parameter was missing.

- **string message** – provides an associated text description of the error message. The message may be empty.

### 6.4.3.3 Pre-Conditions

The MBMS client has received a call via the `registerRTPApp()` API as defined in clause 6.4.3.2.

### 6.4.3.4 Expected MBMS Client Actions

The MBMS client responds accordingly and depending on the response moves to one of the states: IDLE, NOT_AVAILABLE, or REGISTERED. For more details refer to clause 6.4.2.4.

### 6.4.3.5 Usage of Method for Application

Once the application receives a the `registerRTPResponse()` with the `RegResponseCode` set to REGISTER_SUCCESS, the application can proceed with other API interactions with the MBMS client.

If the MBMS client is temporarily in NOT_AVAILABLE, if the `registerRTPResponse()` signaled a failure with a FAILED_LTE_EMBMS_SERVICE_UNAVAILABLE, the application may periodically recheck if the state of the MBMS client changes by retrying the `registerRTPApp()` API.

If the MBMS client is responding with MISSING_PARAMETERS, the application should fix the parameters and retry the `registerRTPApp()` API.

### 6.4.3.6 Post-Conditions

If the MBMS client functions cannot be activated and once the response is sent, then MBMS client is at least temporarily in NOT_AVAILABLE state.

If the MBMS client functions can be activated and respective response is sent, then MBMS client is in REGISTERED state with the REGISTERED parameters as set above.

### 6.4.3.4 Getting information on available MBMS RTP streaming delivery Services

#### 6.4.3.4.1 Overview

This clause defines `getRTPServices()` API call.

The `registerRTPApp()` interface returns the complete list of available MBMS RTP streaming delivery Services information. As illustrated in Figure 6.4-2, after a successful registration with the MBMS client, the MBMS Aware Application can use the `getRTPServices()` API to discover the available MBMS RTP streaming delivery Services associated with the service classes registered via the `registerRTPApp()`.

#### 6.4.3.4.2 Parameters

The `getRTPServices()` API returns a list describing the available MBMS RTP streaming delivery Services, where each service is described by the following output only parameters:
- sequence<serviceNameLang> serviceNameList – optionally provides a list of the service title name in possibly different languages. Each (name, lang) pair defines a title for the service on the language indicated.
  - string name – offers a title for the user service on the language identified in the lang parameter.
  - string lang – identifies a natural language identifier per RFC 3066 [10].
- string serviceClass – identifies the service class which is associated with the service.
- string serviceId – provides the unique service ID for the service. The uniqueness is among all services provided by the BMSC.
- string serviceLanguage – indicates the available language for the service and represented as an identifier per RFC3066 [10].
- EmbmsCommonTypes::ServiceAvailabilityType serviceBroadcastAvailability – signals whether the UE is currently in the broadcast coverage area for the service.
  - The possible values are:
    - BROADCASTAVAILABLE – if content for the service is broadcast at the current device location.
    - BROADCASTUNAVAILABLE – if content for the service is not broadcast at the current device location.
- string sdpUri – provides an HTTP URL where the SDP for the MBMS RTP streaming delivery Service is hosted and available for RTP clients access.
- string interfaceName – provides the network interface name from which the started MBMS RTP streaming delivery Service can be received by the RTP clients.
- EmbmsCommonTypes::Date activeServicePeriodStartTime – signals the current/next active MBMS RTP streaming delivery Service start time, when RTP data starts being broadcasted over the air.
- EmbmsCommonTypes::Date activeServicePeriodEndTime – signals the current/next active MBMS RTP streaming delivery Service stop time, when RTP data stops being broadcasted over the air.

6.4.3.4.3 Pre-Conditions
The MBMS client is in REGISTERED.

6.4.3.4.4 Expected MBMS Client Actions
When this method is invoked, the MBMS client returns the RTP service parameters. For more details refer to clause 6.4.2.4.

6.4.3.4.5 Usage of Method for Application
The application should use this call right after the registerRTPResponse() notification as defined in clause 6.4.3.3 is received or after the rtpServiceListUpdate() notification as defined in clause 6.4.3.6 is received.

The application should use the serviceId to identify the service in subsequent communication with the MBMS client to manage the MBMS RTP streaming delivery service.

The usage of the parameters serviceNameList, serviceClass, serviceBroadcastAvailability, and serviceLanguage is typically up to the application.

The sdpURI should be used by the application to initiate playback by initiating a RTP client. The application should assume that the Media Presentation can be consumed by the RTP client without any further interaction with the MBMS-aware application. The interfaceName should be used by the RTP client to filter the data stream reception from a specific network interface.
The parameters `activeServicePeriodStartTime` and `activeServicePeriodEndTime` provides the application the ability to determine the current broadcast state for the service as follows:

- If the current time is such that `activeServicePeriodStartTime ≤ current time ≤ activeServicePeriodEndTime`, RTP content is being broadcast for the service at the current time.
- If the `activeServicePeriodStartTime` is in the future, there is currently no broadcast being made for the service, but broadcast transmission is currently scheduled to start at this advertised time.
- If the `activeServicePeriodStartTime` is set to zero, there is no currently defined broadcast schedule time for the service.

### 6.4.3.4.6 Post-Conditions

This call does not change the MBMS client state.

The application uses the `serviceId` to identify the service in subsequent communication with the MBMS client.

### 6.4.3.5 Updating the registered service classes

#### 6.4.3.5.1 Overview

This clause defines `setRTPServiceClassFilter()` call.

While an application is actively registered with the MBMS client to consume MBMS RTP streaming delivery Services, the MBMS Aware Application can call the `setRTPServiceClassFilter()` API to update the list of service classes the application wants to be registered with, see figure 6.4.3.5.1-1.

![Figure 6.4.3.5.1-1: Sequence diagram for updating the registered service classes for an application](image)

#### 6.4.3.5.2 Parameters

The parameters for the `setRTPServiceClassFilter()` method are:

- `sequence<string> serviceClassList` – see clause 6.4.3.2.2.
6.4.3.5.3 Pre-Conditions
The application is actively registered with the MBMS client to consume MBMS RTP streaming delivery Services, and MBMS client is in REGISTERED state for the application.

6.4.3.5.4 Expected MBMS Client Actions
When this method is invoked, the MBMS client shall updates the internal parameters and is expected to provide a rtpServiceListUpdate() notification as defined in clause 6.4.3.6. For more details refer to clause 6.4.2.4.

6.4.3.5.5 Usage of Method for Application
The MBMS Aware Application may invoke the setRTPServiceClassFilter() API to update the previously defined new list of service classes that includes additional service classes or includes fewer service classes than the list of service classes.

The application should be aware that the updates are only active once an rtpServiceListUpdate() notification is received that confirms the new service class filters.

6.4.3.5.6 Post-Conditions
The MBMS client issues an rtpServiceListUpdate() notification as defined in clause 6.4.3.6.

6.4.3.6 Updating the RTP Service List

6.3.3.6.1 Overview
This clause defines rtpServiceListUpdate() notification. This notification is used by the MBMS client to inform the application about a successful API call setRTPServiceClassFilter() as shown in Figure 6.4-3 or other updates in RTP service list.

6.3.3.6.2 Parameters
None.

6.3.3.6.3 Pre-Conditions
The MBMS client is in REGISTERED state for the application. The MBMS-aware application has issued a setRTPServiceClassFilter() API call.

6.3.3.6.4 Expected MBMS Client Actions
The MBMS client issues this notification as a response to a successful setRTPServiceClassFilter() API call or to the response to updates of the service list provided in the SDP. For more details see clause 6.4.2.4.

6.3.3.6.5 Usage of Method for Application
The application is informed about the updates of the service class list and may issues a getRTPServices() API call as defined in clause 6.4.3.4 to obtain the updated service list.

6.3.3.6.6 Post-Conditions
The MBMS-aware application has the latest service list. No state change is involved.
6.4.3.7 Start MBMS RTP streaming delivery Service

6.4.3.7.1 Overview

This clause defines startRTPService() API.

After the MBMS RTP streaming delivery Service registration, the MBMS Aware Application can make calls on the startRTPService() API for the MBMS client to start reception of RTP content received over broadcast, as shown in Figure 6.4.3.7.1-1.

![Figure 6.4.3.7.1-1: Application starts MBMS RTP streaming delivery services](image)

6.4.3.7.2 Parameters

The parameters for the startRTPService() API are:

- string serviceId – see clause 6.4.3.4.2.

6.4.3.7.3 Pre-Conditions

The MBMS client is in REGISTERED state.

The application has the latest service list, for example through the getRTPServices() API call as defined in clause 6.4.3.4.

6.4.3.7.4 Usage of Method for Application

The MBMS Aware Application can make calls on the startRTPService() API for the MBMS client to start reception of RTP data over broadcast.

When application is no longer interested in consuming the RTP Service, it should call the stopRTPService() API call as defined in clause 6.4.3.9.
6.3.3.7.5 MBMS Client Actions
When this method is invoked, the MBMS client starts the RTP service, if possible. For more details see clause 6.4.2.4.

6.4.3.7.6 Post-Conditions
The MBMS-aware application expects a serviceStarted() notification as defined in clause 6.4.3.7 or an appropriate error message.

6.4.3.8 Notification that MBMS RTP streaming delivery Service has started

6.4.3.8.1 Overview
Once the MBMS client has successfully collected all necessary information to start the service the MBMS client invokes the serviceStarted() callback function.

6.4.3.8.2 Parameters
The parameters for the serviceStarted() API are:

- string serviceId – see definition in clause 6.4.3.2.2.

6.4.3.8.3 Pre-Conditions
The MBMS application issued a startRTPService() API call.
The MBMS client is in REGISTERED state for the serviceId.

6.4.3.8.4 Expected MBMS Client Actions
The MBMS client issues this notification if the service is started successful. For details see clause 6.4.2.4.

6.4.3.8.5 Usage of Method for Application
Once the application receives the callback on the successful start of the service with the serviceId, the application may start the MBMS RTP streaming delivery service initiating a RTP Media Presentation at a RTP client by handing over the sdpURI received during the registration process for this service.

6.4.3.8.6 Post-Conditions
The RTP client can communicate with the MBMS client. The MBMS client makes available the MBMS RTP streaming delivery service based on the SDP referenced in by the sdpURI of the service.

6.4.3.9 Stop MBMS RTP streaming delivery Service

6.4.3.9.1 Overview
This clause defines stopRTPService() API.

As figure 6.4-4 illustrates, when an MBMS Aware Application that issued a startRTPService() for a service is no longer interested in consuming the RTP content for that service, it will call the stopRTPService() API call.

6.4.3.9.2 Parameters
The parameter for the stopRTPService() API is:

- string serviceId – see definition in clause 6.4.3.2.2.
6.4.3.9.3 Pre-Conditions

The MBMS client is in ACTIVE state for this application.

6.4.3.9.4 Usage of Method for Application

If an MBMS Aware Application is no longer interested in consuming the RTP service, it should call the stopRTPService() API call. Latest at the same time, the Application should inform the RTP client about the termination of the service and the RTP client should no longer receive data that are referenced by the sdpURI.

6.4.3.9.5 MBMS Client Actions

The MBMS terminates the reception. For more details see clause 6.4.2.5.

6.4.3.9.6 Post-Conditions

The MBMS client is in REGISTERED state. The Media Presentation referenced by the sdpURI can no longer be accessed as the referenced data will no longer be provided at the announced location in the SDP.

6.4.3.10 MBMS RTP streaming delivery Service De-registration

6.4.3.10.1 Overview

This clause defines deregisterRTPApp() API.

An MBMS Aware Application registers services classes with the MBMS client to request the start of streaming for MBMS RTP streaming delivery Services. The MBMS Aware Application that registered with the MBMS client via the registerRTPApp() API should invoke the deregisterRTPApp() before exiting. An implicit stopRTPService() call is performed for all MBMS RTP streaming delivery Services that have been started since the last registerRTPApp() call. If there are no application interested in an MBMS RTP streaming delivery Service, the MBMS client stops capturing data for this Service.

The MBMS client stops monitoring for Service Announcement updates when there are no applications registered. There are no parameters for the registerRTPApp() API.

6.4.3.10.2 Parameters

None.

6.4.3.10.3 Pre-Conditions

The MBMS client is in REGISTERED state for this application.

6.4.3.10.4 Usage of Method for Application

MBMS Aware Application registered with the MBMS client via the registerRTPApp() API should invoke the deregisterRTPApp() before exiting.

6.4.3.10.5 MBMS Client Actions

The MBMS client no longer sends notifications and clears all context for the Application.

6.4.3.10.6 Post-Conditions

The app is no longer registered with the MBMS client.

The MBMS client is in IDLE mode.
6.4.3.11 Notification that MBMS RTP streaming delivery Service has stalled

6.4.3.11.1 Overview

This clause the serviceStalled() notification.

The MBMS client enables consumption of a MBMS RTP streaming delivery Service if the current setting for serviceBroadcastAvailability is BROADCAST_AVAILABLE or BROADCAST_UNAVAILABLE. Other circumstances may also prevent the broadcast reception of that service (e.g., a frequency conflict). In these circumstances, the MBMS client will signal the application that the service is temporarily not available for playback by invoking the serviceStalled() API.

When broadcast reception of the service is re-established, the MBMS client will signal the application that the service is again available for playback by invoking the serviceStarted() API. This is illustrated in Figure 6.4-5.

![Figure 6.4-5: Signaling that a MBMS RTP streaming delivery service stalled](image)

6.4.3.11.2 Parameters

The parameter for the serviceStalled() API are:

- **string serviceId** – identifies the MBMS RTP streaming delivery Service for which broadcast receptions have temporarily stalled.

- **StalledReasonCode reason** – provides specific information on what caused the service to stall. Valid options are:
  - **RADIO_CONFLICT** – indicates a frequency conflict, namely the service requested to be started via a startRTPService() cannot be started at this time since the MBMS client is actively receiving another service on a different frequency band.
  - **END_OF_SESSION** – indicates that playback has reached the end of the scheduled transmission for the service as described by the schedule description fragment for the service. This should indicate that the advertised activeServicePeriodEndTime time has been reached.
  - **OUT_OF_COVERAGE** – indicates a UE mobility event to an area where the service is not available via broadcast.
- **STALLD_UNKNOWN_REASON** – indicates that another unspecified condition caused the service interruption.

### 6.4.3.11.3 Pre-Conditions

The MBMS client is in **ACTIVE** mode.

### 6.4.3.11.4 Expected MBMS Client Actions

The MBMS client provides a `serviceStalled()` notification in case it can no longer provide the referenced resources in the Media Presentation provided with `sdpURI`. For more details refer to clause 6.4.2.5.

### 6.4.3.11.5 Usage of Method for Application

The MBMS Aware Application should stop the RTP client playback on reception of the `serviceStalled()` notification. However, unless the application is no longer interested in the content, it should not issue a `stopRTPService()` call in order to allow the MBMS client from trying to collect RTP content once the download problem is resolved. The application should inform the user of the temporary service interruption.

If the RTP client maintains in STALLED state for too long, the application should stop the service by issuing a `stopRTPService()`.

### 6.4.3.11.6 Post-Conditions

The MBMS client is in **STALLED** mode.

### 6.4.3.12 Notification of MBMS RTP streaming delivery Service errors

#### 6.4.3.12.1 Overview

This clause defines the `rtpServiceError()` notification.

As illustrated in Figure 6.4-5, the `startRTPService()` request from an MBMS Aware Application may not be served, so the MBMS client will send a failure indication via the `rtpServiceError()` to signal the error code for the result of processing the application's `startRTPService()`.

![Figure 6.4-5: Signaling errors with the startRTPService() request from the RTP-over-MBMS](image)

Figure 6.4-5 also illustrates that the `rtpServiceError()` is used to signal the error code for the result of processing the application's `stopRTPService()` request.
6.4.3.12.2 Parameters

The parameters for the `rtpServiceError()` API are:

- **string serviceId** – identifies the MBMS RTP streaming delivery Service on which the MBMS client failed.

- **RTPErrorCode errorCode** – identifies the error code for the reason causing the `startRTPService()` or the `stopRTPService()` request for the serviceId to fail. The available error codes are:
  - `RTP_INVALID_SERVICE` – signals that serviceID defined on the `startRTPService()` or the `stopRTPService()` request is not currently defined or it is not associated with the service classes with the MBMS Aware Application is registered.
  - `RTP_UNKNOWN_ERROR` – signals an error condition not explicitly identified.

- **string errorMsg** – may provide additional textual description of the error condition.

6.4.3.12.3 Pre-Conditions

The MBMS client has received a the `startRTPService()` or a `stopRTPService()` request.

6.4.3.12.4 Expected MBMS Client Actions

The MBMS client will send a failure indication via the `rtpServiceError()` to signal the error code for the result of processing the application. For more details refer to clauses 6.4.2.4 and 6.4.2.5.

6.4.3.12.5 Usage of Method for Application

If the MBMS Aware application receives this notification, it should revalidate the capture call. The application should also update the service list by issuing a `getRTPServices()` as defined in clause 6.4.3.4.

6.4.3.12.6 Post-Conditions

No state change is applied.
6.4.3.13 Checking the version for MBMS RTP streaming delivery Service interface

6.4.3.13.1 Overview
This clause defines the getVersion() request function.

6.4.3.13.2 Parameters
The parameters for the getVersion() API call are:
- string version – identifies the version of the MBMS clients API implementation.

6.4.3.13.3 Pre-Conditions
The MBMS client may be in any state.

6.4.3.13.4 Usage of Method for Application
In order for the MBMS Aware Application to know the version of the MBMS RTP streaming delivery Service interface, the getVersion() API may be used. If the version number is not supported by the application, it should deregister and not use the API.

6.4.3.13.5 MBMS Client Actions
The getVersion() API returns the version of the implemented APIs of the MBMS client.

6.4.3.13.6 Post-Conditions
No state changes apply.

7 MBMS Client to Application Interfaces for Data

7.1 Introduction
This section provides an overview of potential interfaces between the MBMS client and the MBMS-aware application for the data delivered over the MBMS system. The interfaces are typically within the UE, but may also be supported over the network. The interfaces may be used by implementations by referring to the capabilities of the interfaces defined in this clause.

7.2 File Copy Interface
The MBMS client may copy files delivered by MBMS User Services to a local file storage that is controlled by the MBMS aware application. The application is responsible for the management of the storage.

7.3 HTTP Interface
The MBMS client may provide an HTTP server such that the MBMS-aware application can access the files delivered over the MBMS User services by using regular HTTP Methods.

MBMS-aware applications communicating with the MBMS client over HTTP should support partial-file-accept requests and partial file responses as defined in TS 26.346 [5], clause 7.9.2.1.

Without excluding other response options, as a response to a partial-file-accept request using a regular HTTP GET request an MBMS aware application may typically receive one of the following responses:

1) 200 OK with Content-Type set to the Media Type of the requested object
2) 200 OK with the Content-Type set to application/3gpp-partial and the message format according to the definition in clause 7.9.2.2 of TS 26.346 [5].

3) 416 Requested Range Not Satisfiable with the additional information according to the definition in clause 7.9.2.2 of TS 26.346 [5].

4) 404 Not Found.

Case 1 is the regular response.

Guidelines for handling request responses according to case 4 from above are provided in clause A.7 of TS 26.247 [6]. Guidelines for handling request responses 2 and 3 from above are provided in clause A.9 of TS 26.247 [6].

7.4 DASH-Specific Interfaces

7.4.1 Introduction

The MBMS client when providing a DASH Streaming Application User Services should implement the generic HTTP interface as defined in clause 7.3.

The MBMS client may implement functions of a DASH server as defined in TS 26.247 [7]. In this case the MBMS client modifies the MPD and possibly other DASH resources to provide a valid Media Presentation. Note that in this case, no specific functions in the DASH client may be required. More details are provided in clause 7.4.2.

7.4.2 MBMS Client as DASH Server

7.4.2.1 General

The MBMS client may rewrite the MPD to offer a valid service based on the data received in the DASH-over-MBMS service. Typical operations that the MBMS client may have to implement:

- Ensure that the URLs of the DASH Resources in the MPD resolve to the location at which the MBMS client provides the resources delivered through the MBMS User Service
- Ensure that the timeshift buffer expressed in the MPD does not refer to non-available resources
- Ensure that the availability times of the DASH resources on the MBMS clients DASH Server are correctly documented in the MPD
- Ensure that MPD Updates are done sufficiently often, for example by setting the \texttt{@minimumUpdatePeriod} to 0 in order for the DASH client to revalidate the MPD with every Segment request.

Some specific functions are provided in the following.

7.4.2.2 Time Synchronization

The MBMS client if providing the content as a DASH server should offer the Time Synchronization as defined in clause 11.5.2 of TS 26.247 [7].

The DASH client of the MBMS aware application should support the Time Synchronization as defined in clause 11.5.3 of TS 26.247 [7].

7.4.2.3 Robustness

The MBMS client if providing the content as a DASH server may implement the Robustness Tools on the server as defined in clause 11.6 of TS 26.247 [7].

The DASH client of the MBMS aware application may support the Robustness Tools on the client as defined in clause 11.5.3 of TS 26.247 [7].
7.5 RTP Streaming Delivery Method Interface

The MBMS Client should provide an interface such that the data delivered using the MBMS Streaming delivery method can a packet stream that complies with a media format that can be decoded by the media receiver part of the MBMS client. As an example:

- The MBMS Client may implement the functions of the "Hypothetical FEC Decoder" as defined in clause 8.2.2.11 of TS 26.346 [5],
- The MBMS Client may provide the application with:
  - A SDP that describes the data stream.
  - The network interface from which the data stream can be received. For that purpose, the MBMS Client may forward the packets locally, e.g. through a virtual network interface, or through the network to the client. In such example, The MBMS client shall modify the SDP accordingly.

8 MBMS URLs: Definition and URL Handling

8.1 General

This clause defines different MBMS URLs and the associated URL handling.

The single resource MBMS URL form "mbms://" is defined in clause 8.2.

NOTE: The specification does not define a URL for all Application User Services defined in clause 4.3, but only a subset.

8.2 Single Resource MBMS URL handling

8.2.1 Introduction

An MBMS URL identifies a resource that is made available over MBMS Download Delivery Service using the File Download Application User Service as defined in clause 4.2.3. It is therefore similar in meaning to other URL forms that deliver 'file' resources, such as "http:", "ftp:" and "file:"

MBMS URLs are processed by a hypothetical MBMS URL Handler as shown in Figure 8.2.1-1.

The position of the MBMS URL Handler, and its interfaces are illustrated by the logical model shown in Figure 8.2.1-1. In that figure URL usage is shown as an alternative to an application written to use MBMS services using the MBMS-API (left side of the diagram, described elsewhere in the present document).

The MBMS URL handler is positioned within the logical model of a system that has library support for fetching resources (files) referred to by URLs. In the model an (unchanged) existing, or new, application supports URLs that address 'file' resources. That application uses a generic URL resolution library ('Generic URL Resolution' in the diagram) to return the identified resource when the application needs the resource identified by a URL.

The MBMS URL handler may use MBMS-API functions to communicate with the MBMS client.

The logical model is that the generic handler supports returning the resource given a URL of any type. That generic handler is supported by a set of protocol-specific handlers; by inspecting the scheme part of the URL (e.g. "http:" the generic handler in turn requests the resource of the appropriate protocol-specific handler. The request and response interfaces to the generic handler, and the protocol-specific modules are defined by the library (e.g. they may be object-oriented, function-based, or message-based). The present document defines the behaviour of the MBMS URL handler; however its request interface is defined by the library and environment which it fits into. The MBMS protocol-specific handler decomposes the URL form, and, using the MBMS-APIs, initiates the acquisition of the MBMS User service by the MBMS client that permits access to the identified resource, and acquisition of the indicated resource from that service, and returns that resource. The behaviour of the MBMS URL handler is specified in this clause.
8.2.2 URL structure, definition and behaviour

The Single Resource MBMS URL is composed of a prefix, mid-part, and suffix.

The prefix is a URL that is the serviceId of the service on which the resource is available. The suffix contains a URI that is the identifier of the desired resource. The mid-part currently has no defined content.

When a content provider wishes to use MBMS URL forms to identify resources made available by them over MBMS, they shall use the prefix part of an MBMS URL as serviceId for the service. The creator of the serviceId URI shall be authorized by the 'authority' (see below) identified in that serviceId.

The prefix starts with the scheme-name "mbms://" followed by a double-slash "//", followed by an authority and an optional path, as defined for "http: " by RFC 7230 [14] with the restriction that the prefix shall not contain the character "&".

NOTE: The "//" means that the MBMS scheme is hierarchical and that relative URLs are permitted, and that they are effectively composed against the suffix part. Relative URL composition is not in the scope of the present document; a relative URL is, of course, composed against its base, and if the final result is an MBMS URL as defined here, then that URL is presented to the handler.

The mid-part consists of zero or more &name=value pairs. There are no currently defined mid-part pairs; they shall not be present in URLs and shall be ignored if present.
The suffix is optional and consists of the string "&label=" followed by the URI which contains identifier of the desired resource (and optionally, as for all URIs, a query or fragment part). The suffix is terminated by the end of the URL.

(Note that the use of "&" used here is not part of a query or fragment, as there is no preceding "?" or ";". "&" is in the main body of the URL where it is a legal character.)

The formal ABNF, following the syntax of RFC 7230 (HTTP URLs) [14] and RFC 3986 (URLs) [11]:

```
mbms-URI = "mbms:.chars" // authority path-abempty
           *( "&" mid-label ="chars" mid-value )
           [ "&label=" resourceURI ]
authority = <authority, see [RFC3986], Section 3.2>
path-abempty = <path-abempty, see [RFC3986], Section 3.3>
mid-label = ALPHA *( ALPHA / DIGIT )
mid-value = 1*uchar
           = unreserved / pct-encoded / ";" / "?" / ":" /
             "@" / "=" / ":" / ";" / ";" / "#" / /";
unreserved = <unreserved, see [RFC3986], Section 2.3>
pct-encoded = <pct-encoded, see [RFC3986], Section 2.1>
resourceURI = <URI, see [RFC3986], Section 3>
```

The handler performs decomposition of the URI into the prefix, mid-part, and suffix.

If the URI passed to the handler lacks the suffix part (there is no "&label="), then the handler retrieves the DNS URI record, if any, from the hostname identified by the authority part of the prefix. The handler forms a new URI by adding to the passed URI:

a) the value of path-abempty in the syntax, if it is empty in the passed URI and non-empty in the DNS URI.

b) all mid-part name=value pairs in the returned URI that have no matching name in the passed URI.

c) the suffix from the returned URI.

If this operation succeeds in building a new URI that has a suffix, the handler returns a Redirect to this new URI; otherwise it returns an error.

Otherwise, the serviceId is set to the prefix (the substring of the URL before the first "&") and the resourceLabel is set to portion of the resourceURI preceding the fragment part, if any. The MBMS API is called to return the resource identified by resourceLabel from the service identified by serviceId.

The MBMS-API and the MBMS Client are responsible for:

1. finding the service with the given serviceId among the available services; the serviceClass is empty. This is done by
   a) registering;
   b) asking for the available services;
   c) issuing a start capture.

2. checking the availability time interval of the resource;
   a) provide the schedule as defined in.

3. finding and returning to the MBMS URL Handler the resource on the given service;
   a) notify the MBMS URL handler by the notification if successful or notification if an error occurs.

The MBMS URL handler is responsible for:

1) keeping the service open for some "keep-alive" time in the expectation of further calls for resources from the same service, by staying registered;

2) caching resources received on the service;
3) sharing that cache with other protocol handlers;
4) returning the resource, or returning errors or redirects, translating the return value(s) from the MBMS APIs as appropriate.

8.2.3 Examples

mbms://www.example.com/sample&label=http://v.example.com/sample.html#p6

- the serviceId is mbms://www.example.com/sample;
- the label of the desired resource is http://v.example.com/sample.html.
Annex A (informative):
Documentation Guidelines for APIs

A.1 Introduction Motivation

As the present document is primarily targeted at developers that use the MBMS function a few principle agreements were made.

1) The specification should set good practices for future API definition in 3GPP

2) The specification requires clear definitions of interface, function/element, messages, API, resource, etc.

3) The interfaces should be documented in the following manner:
   a) Consistent graphical presentation
   b) IDL for interface and message description
   c) Doxygen for semantical description
   d) Example Use Cases and Message Flows

4) The semantical description and messages flows include messages sent and received on each function as well as pre/post/error conditions.

5) As IDL enables easy conversion to different languages, no program-language specific APIs (e.g. JSON, Java, or C) are necessary, but may in general not be prohibited. If IDL can provide a non-ambiguous translation to JSON, Java and C, then the documentation may be informative, otherwise it may be added to the normative specification as a reference able option.

Based on these considerations, some suggested documentation details are provided

A.2 Documentation Details

A.2.0 General

A graphical presentation of the interface is encouraged. Figure A.1 shows some examples using an informal notation. The existence of an interface can be implied even without using an explicit symbol for it. If a relationship symbol joins an element/function symbol and the relationship type involves an interaction—as opposed to, say, "is a subclass of," that implies that the interaction takes place through the element's interface.
A.2.1 IDL for Interface Specification

Interface Definition Language (IDL) [9] is a standard language for defining function and method interfaces. It supports common primitive data types. Some of the base data types supported by IDL are int, Boolean, byte, char, double, float, long, short, and void*. IDL also supports signed and unsigned qualifiers, enumerations and more.

IDL’s data types and definitions are both language-neutral and platform-neutral. This enables the definition of a common interface that may be implemented by different modules or components irrespective of the language and platform. An IDL interface provides a description of the functionality that will be provided by an object. It provides all of the information needed to develop clients that use the interface.

While IDL is not a programming language, there are tools that map IDL to just about every major programming language.

Below is a sample IDL definition of "order"

```idl
interface order {
    float calculate_tax ([in] float taxable_amount);
    float calculate_total([in] item_list items);
    bool place_order([in,out] item_list items);
}
```

A.2.2 IDL as Data Format

IDL is also proposed as the data format for message exchange.

A.2.3 Doxygen for API Semantics

Doxygen is a cross-platform documentation system for C++, Java, C, and IDL, etc. It provides a mechanism to document code syntax and semantics. It allows tagging comments in code that will be used to generate nicely formatted output. Available tags enables capturing methods, parameters, pre and post conditions for calling methods as well as highlighting error condition and exceptions.
Doxygen can be used to generate on-line class browser (in HTML) and/or an off-line reference manual from a set of source files. Below is a sample of Doxygen comments for a function definition.

```c
/**
 * @name binary_search
 * @brief Search a array for a value using binary search.
 * @param[in] a Array of floats.
 * @param[in] n Number of elements of @a a to search.
 * @param[in] v Value to search for.
 * @return An index into array @a a or -1.
 *
 * @pre 0 <= n <= Size of the array @a a.
 * @pre For all i, j with 0 <= i < j < @a n, @a a[i] <= @a a[j].
 * @post (0 <= result < @a n and @a a[result] == @a v)
 *     or (result == -1 and there is no i, 0 <= i < @a n, s.t. @a a[i] == @a v).
 */
int binary_search(const float* a, int n, float v)
```

### A.2.4 Use Cases and Message Flows

Message flows (sequence diagrams) are an interaction diagram that shows the objects/modules participating in a particular interaction and the messages they exchange arranged in a time sequence.

Annex C (informative): IANA registration for MBMS URLs

C.1 General

This Annex provides the MBMS URL registration information that is referenced from the IANA registry at
http://www.iana.org/ and follows the template per RFC 7595 [13], clause 7.4.

C.2 IANA Registration for Single Resource MBMS URL

Scheme name:
- mbms

Status:
- Permanent

Applications/protocols that use this scheme name:
- 3GPP file delivery over multicast-broadcast as specified in 3GPP TS 26.346 "Multimedia Broadcast/Multicast Service (MBMS)" and 3GPP TS 26.347 "MBMS URLs and APIs"

Contact:
3GPP Specifications Manager
3gppContact@etsi.org
+33 (0)492944200

Change controller:
3GPP SA WG4

References:
- 3GPP TS 26.347 "MBMS URLs and APIs"
Security Considerations:

- The security considerations of section 7 of RFC 3986 apply. Maliciously constructed or other erroneous URIs may cause the MBMS API to search for non-existent services. Currently this is defined to be a local search, and not to perform a network interaction, but if a terminal were to contact network servers in an attempt to retrieve the service description, then providing such a URI to many user-agents simultaneously could cause network or server overload.
Annex D (informative):
