Digital cellular telecommunications system (Phase 2+) (GSM);
GSM/EDGE Modulation
(3GPP TS 45.004 version 14.1.0 Release 14)
Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for ETSI members and non-members, and can be found in ETSI SR 000 314: "Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (https://ipr.etsi.org/).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Specification (TS) has been produced by ETSI 3rd Generation Partnership Project (3GPP).

The present document may refer to technical specifications or reports using their 3GPP identities, UMTS identities or GSM identities. These should be interpreted as being references to the corresponding ETSI deliverables.

The cross reference between GSM, UMTS, 3GPP and ETSI identities can be found under http://webapp.etsi.org/key/queryform.asp.

Modal verbs terminology

In the present document "shall", "shall not", "should", "should not", "may", "need not", "will", "will not", "can" and "cannot" are to be interpreted as described in clause 3.2 of the ETSI Drafting Rules (Verbal forms for the expression of provisions).

"must" and "must not" are NOT allowed in ETSI deliverables except when used in direct citation.

Foreword

This Technical Specification has been produced by the 3rd Generation Partnership Project (3GPP).

The contents of the present document are subject to continuing work within the TSG and may change following formal TSG approval. Should the TSG modify the contents of the present document, it will be re-released by the TSG with an identifying change of release date and an increase in version number as follows:

Version x.y.z

where:

x  the first digit:
   1  presented to TSG for information;
   2  presented to TSG for approval;
   3  or greater indicates TSG approved document under change control.

y  the second digit is incremented for all changes of substance, i.e. technical enhancements, corrections, updates, etc.

z  the third digit is incremented when editorial only changes have been incorporated in the document.
1 Scope

The modulator receives the bits from the encryption unit, see 3GPP TS 45.001, and produces an RF signal. The filtering of the Radio Frequency (RF) signal necessary to obtain the spectral purity is not defined, neither are the tolerances associated with the theoretical filter requirements specified. These are contained in 3GPP TS 45.005.

1.1 References

The following documents contain provisions which, through reference in this text, constitute provisions of the present document.

- References are either specific (identified by date of publication, edition number, version number, etc.) or non-specific.
- For a specific reference, subsequent revisions do not apply.
- For a non-specific reference, the latest version applies. In the case of a reference to a 3GPP document (including a GSM document), a non-specific reference implicitly refers to the latest version of that document in the same Release as the present document.

[2] 3GPP TS 45.001: “Physical Layer on the Radio Path (General Description)”.
[3] 3GPP TS 45.002: “Multiplexing and multiple access on the radio path”.
[6] 3GPP TS 44.060: “Radio Link Control/ Medium Access Control (RLC/MAC) protocol”.

</tbody>
</table>

2 Modulation format for GMSK

2.1 Modulating symbol rate

The modulating symbol rate is the normal symbol rate which is defined as \( \frac{1}{T} = \frac{1}{1625/6} \text{ ksymb/s} \) (i.e. approximately 270.833 ksymb/s), which corresponds to \( 1 \text{ 625/6 kbit/s} \) (i.e. 270.833 kbit/s). \( T \) is the normal symbol period (see 3GPP TS 45.010).
2.2 Start and stop of the burst

Before the first bit of the bursts as defined in 3GPP TS 45.002 enters the modulator, the modulator has an internal state as if a modulating bit stream consisting of consecutive ones ($d_i = 1$) had entered the differential encoder. Also after the last bit of the time slot, the modulator has an internal state as if a modulating bit stream consisting of consecutive ones ($d_i = 1$) had continued to enter the differential encoder. These bits are called dummy bits and define the start and the stop of the active and the useful part of the burst as illustrated in figure 1. Nothing is specified about the actual phase of the modulator output signal outside the useful part of the burst. In case of EC operation, the phase during the useful part of contiguous bursts, belonging to the same blind physical layer transmissions within a TDMA frame, has a fixed relation, see subclauses 2.6 and 2.7.

![Diagram of dummy bits, tail bits, and useful part](image)

**Figure 1:** Relation between active part of burst, tail bits and dummy bits. For the normal burst the useful part lasts for 147 modulating bits.

2.3 Differential encoding

Each data value $d_i = \{0,1\}$ is differentially encoded. The output of the differential encoder is:

$$\hat{d}_i = d_i \oplus d_{i-1} \quad (d_i \in \{0,1\})$$

where $\oplus$ denotes modulo 2 addition.

The modulating data value $\alpha_i$ input to the modulator is:

$$\alpha_i = 1 - 2\hat{d}_i \quad (\alpha_i \in \{-1,+1\})$$

2.4 Filtering

The modulating data values $\alpha_i$ as represented by Dirac pulses excite a linear filter with impulse response defined by:

$$g(t) = h(t) * \text{rect}\left(\frac{t}{T}\right)$$

where the function $\text{rect}(x)$ is defined by:

$$\text{rect}\left(\frac{t}{T}\right) = \frac{1}{T} \quad \text{for} \ |t| < \frac{T}{2}$$
\[
\text{rect}\left(\frac{t}{T}\right) = 0 \quad \text{otherwise}
\]

and * means convolution. \( h(t) \) is defined by:

\[
h(t) = \exp\left(-\frac{t^2}{2\sigma^2 T^2}\right) \sqrt{(2\pi) \cdot \delta T}
\]

where

\[
\sigma = \frac{\ln(2)}{2\pi BT} \quad \text{and} \quad BT = 0.3
\]

where \( B \) is the 3 dB bandwidth of the filter with impulse response \( h(t) \). This theoretical filter is associated with tolerances defined in 3GPP TS 45.005.

### 2.5 Output phase

The phase of the modulated signal is:

\[
\phi(t') = \sum_{i} \alpha_i \pi h \int_{-\infty}^{t'-iT} g(u) du
\]

where the modulating index \( h \) is ½ (maximum phase change in radians is \( \pi/2 \) per data interval).

The time reference \( t' = 0 \) is the start of the active part of the burst as shown in figure 1. This is also the start of the bit period of bit number 0 (the first tail bit) as defined in 3GPP TS 45.002.

### 2.6 Modulation

The modulated RF carrier, except for start and stop of the TDMA burst or ESAB (see 3GPP TS 45.002 [3]) may therefore be expressed as:

\[
x(t') = \sqrt{\frac{2E_c}{T}} \cdot \cos(2\pi f_0 t' + \phi(t') + \phi_0)
\]

where \( E_c \) is the energy per modulating bit, \( f_0 \) is the centre frequency and \( \phi_0 \) is a random phase and is constant during one burst or ESAB (see 3GPP TS 45.002 [3]).

In case of EC operation when using blind physical layer transmissions (see 3GPP TS 43.064 [7]) the modulated RF carrier, except for start and stop of the burst may, for each blind physical layer transmission of a burst for which phase and amplitude coherency is required (see 3GPP TS 45.005 [4]), be expressed as:

\[
x(t') = \sqrt{\frac{2E_c}{T}} \cdot \cos(2\pi f_0 (t' + t_0) + \phi(t') + \phi_{157} + \phi_0)
\]

where

- \( t_0 \) is a burst-specific time offset, constant during one burst, and is defined as the time difference between time instant \( t' = 0 \) for the current burst and \( t' = 0 \) for the first transmission of the same burst in the current TDMA frame.
- \( \phi_{157} \) is a phase shift of either 0 or \( \pi h \), and is constant during one burst.
- $\varphi_0$ is a random phase and is constant during all blind physical layer transmissions of the same burst within the same TDMA frame.

For EC-GSM_IoT, only integer timeslot lengths are allowed (see 3GPP TS 45.010 [5]). If any blind physical layer transmission is transmitted in the uplink on timeslot 0 or timeslot 4, which are 157 symbols long, all following blind physical layer transmissions of the same burst in that TDMA frame shall be shifted in phase by $\pi h$, i.e. $\varphi_{157} = \pi h$, otherwise $\varphi_{157} = 0$. For the downlink this phase shift shall not be applied, i.e. $\varphi_{157} = 0$.

### 2.7 Overlaid CDMA

In the case of Overlaid CDMA the modulated RF carrier may be expressed with an additional term compared to subclause 2.6 representing the Overlaid CDMA code:

$$ x(t') = \sqrt{\frac{2E_t}{T}} \cdot \cos(2\pi f_0 (t'+t_0) + \varphi(t') + \varphi_{157} + \varphi_0 + OC \cdot \pi) $$

where $OC$ equals 0 or 1 in accordance with the applied Overlaid CDMA code (see 3GPP TS 45.002 [3]) and is constant during one burst. For each blind physical layer transmission within a TDMA frame, $OC$ equals its respective Overlaid CDMA code element. For example for Overlaid CDMA code 0,0,1,1, $OC$ equals 0 for the first two blind physical layer transmissions and 1 for the last two blind physical layer transmissions within a TDMA frame.

**NOTE:** If the blind physical layer transmissions within a TDMA frame are continuously modulated, a phase shift of $\pi$ between two bursts can be well approximated by inverting all the bits of the second burst, including three to five guard bits preceding and following the tail bits, respectively.

### 3 Modulation format for 8PSK

#### 3.1 Modulating symbol rate

The modulating symbol rate is the normal symbol rate which is defined as $1/T = 1625/6$ ksymb/s (i.e. approximately 270.833 ksymb/s), which corresponds to $3 \times 1625/6$ kbit/s (i.e. 812.5 kbit/s). $T$ is the normal symbol period (see 3GPP TS 45.010).

#### 3.2 Symbol mapping

The modulating bits are Gray mapped in groups of three to 8PSK symbols by the rule

$$ s_j = e^{j2\pi l/8} $$

where $l$ is given by table 1.
### Table 1: Mapping between modulating bits and the 8PSK symbol parameter $l$.  

<table>
<thead>
<tr>
<th>Modulating bits $d_{3i}, d_{3i+1}, d_{3i+2}$</th>
<th>Symbol parameter $l$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(1,1,1)</td>
<td>0</td>
</tr>
<tr>
<td>(0,1,1)</td>
<td>1</td>
</tr>
<tr>
<td>(0,1,0)</td>
<td>2</td>
</tr>
<tr>
<td>(0,0,0)</td>
<td>3</td>
</tr>
<tr>
<td>(0,0,1)</td>
<td>4</td>
</tr>
<tr>
<td>(1,0,1)</td>
<td>5</td>
</tr>
<tr>
<td>(1,0,0)</td>
<td>6</td>
</tr>
<tr>
<td>(1,1,0)</td>
<td>7</td>
</tr>
</tbody>
</table>

This is illustrated in figure 2.

#### 3.3 Start and stop of the burst

Before the first bit of the bursts as defined in 3GPP TS 45.002 enters the modulator, the state of the modulator is undefined. Also after the last bit of the burst, the state of the modulator is undefined. The tail bits (see 3GPP TS 45.002) define the start and the stop of the active and the useful part of the burst as illustrated in figure 3. Nothing is specified about the actual phase of the modulator output signal outside the useful part of the burst.

![Figure 3: Relation between active part of burst and tail bits. For the normal burst the useful part lasts for 147 modulating symbols](image-url)
3.4 Symbol rotation

The 8PSK symbols are continuously rotated with $3\pi/8$ radians per symbol before pulse shaping. The rotated symbols are defined as

$$\hat{s}_i = s_i \cdot e^{j3\pi i/8}$$

3.5 Pulse shaping

The modulating 8PSK symbols $\hat{s}_i$ as represented by Dirac pulses excite a linear pulse shaping filter. This filter is a linearised GMSK pulse, i.e. the main component in a Laurent decomposition of the GMSK modulation. The impulse response is defined by:

$$c_0(t) = \begin{cases} 
\prod_{i=0}^{3} S(t + iT), & \text{for } 0 \leq t \leq 5T \\
0, & \text{else}
\end{cases}$$

where

$$S(t) = \begin{cases} 
\sin(\pi \int_0^t g(t')dt'), & \text{for } 0 \leq t \leq 4T \\
\sin(\pi t - \pi \int_0^{4T} g(t')dt'), & \text{for } 4T < t \leq 8T \\
0, & \text{else}
\end{cases}$$

and

$$g(t) = \frac{1}{\sqrt{T}} \left( Q(2\pi \cdot 0.3 \cdot \frac{t - ST/2}{T \log_2(2)}) - Q(2\pi \cdot 0.3 \cdot \frac{t - 3T/2}{T \log_2(2)}) \right)$$

and

$$Q(t) = \int_{t}^{\infty} e^{-\tau^2} d\tau.$$

The base band signal is

$$y(t') = \sum_{i} \hat{s}_i \cdot c_0(t' - iT + 2T)$$

The time reference $t' = 0$ is the start of the active part of the burst as shown in figure 3. This is also the start of the symbol period of symbol number 0 (containing the first tail bit) as defined in 3GPP TS 45.002.

3.6 Modulation

The modulated RF carrier during the useful part of the burst is therefore:

$$x(t') = \sqrt{\frac{2E_s}{T}} \Re[y(t') \cdot e^{j(2\pi f_0 t' + \phi_0)}]$$

where $E_s$ is the energy per modulating symbol, $f_0$ is the centre frequency and $\phi_0$ is a random phase and is constant during one burst.
4 Modulation format for 16QAM and 32QAM at the normal symbol rate

4.1 Modulating symbol rate

The modulating symbol rate is the normal symbol rate which is defined as $1/T = 1625/6$ ksymb/s (i.e. approximately 270.833 ksymb/s), which corresponds to $4 \times 1625/6$ kbit/s (i.e. approximately 1083.3 kbit/s) for 16QAM and to $5 \times 1625/6$ kbit/s (i.e. approximately 1354.2 kbit/s) for 32QAM. $T$ is the normal symbol period (see 3GPP TS 45.010).

4.2 Symbol mapping

The modulating bits are mapped to symbols according to Table 2 for 16QAM and Table 3 for 32QAM.

**Table 2: Mapping between modulating bits and 16QAM symbols.**

<table>
<thead>
<tr>

</tbody>
</table>

#### 4.3 Start and stop of the burst

Before the first bit of the bursts as defined in 3GPP TS 45.002 enters the modulator, the state of the modulator is undefined. Also after the last bit of the burst, the state of the modulator is undefined. The tail symbols (see 3GPP TS 45.002) define the start and the stop of the active and the useful part of the burst as illustrated in figure 4. Nothing is specified about the actual phase of the modulator output signal outside the useful part of the burst.
4.4 Symbol rotation

The symbols are continuously rotated with $\phi$ radians per symbol before pulse shaping, where $\phi = \pi/4$ and $-\pi/4$ for 16QAM and 32QAM respectively. The rotated symbols are defined as

$$\hat{s}_i = s_i \cdot e^{i\phi}$$

4.5 Pulse shaping

The modulating symbols $\hat{s}_i$ as represented by Dirac pulses excite a linear pulse shaping filter. This filter is the linearised GMSK pulse as defined in 3.5.

4.6 Modulation

The modulated RF carrier during the useful part of the burst is:

$$x(t') = \sqrt{\frac{2E_s}{T}} \Re\left[y(t') \cdot e^{j2\pi f_0 t' + \phi_0}\right]$$

where $y(t')$ is the base band signal (see 3.5), $E_s$ is the energy per modulating symbol, $f_0$ is the centre frequency and $\phi_0$ is a random phase and is constant during one burst.

5 Modulation format for QPSK, 16QAM and 32QAM at the higher symbol rate

5.1 Modulating symbol rate

The modulating symbol rate is the higher symbol rate which is defined as $1/T = 325$ ksymb/s, which corresponds to 650 kbit/s for QPSK, to 1300 kbit/s for 16QAM and to 1625 kbit/s for 32QAM. $T$ is the reduced symbol period (see 3GPP TS 45.010).
5.2 Symbol mapping

The modulating bits are mapped to symbols according to Table 4 for QPSK, Table 2 for 16QAM and Table 3 for 32QAM.

5.3 Start and stop of the burst

Before the first bit of the bursts as defined in 3GPP TS 45.002 enters the modulator, the state of the modulator is undefined. Also after the last bit of the burst, the state of the modulator is undefined. The tail symbols (see 3GPP TS 45.002) define the start and the stop of the active and the useful part of the burst as illustrated in figure 5. Nothing is specified about the actual phase of the modulator output signal outside the useful part of the burst.

5.4 Symbol rotation

The symbols are continuously rotated with $\varphi$ radians per symbol before pulse shaping, where $\varphi = 3\pi/4, \pi/4$ and $-\pi/4$ for QPSK, 16QAM and 32QAM respectively. The rotated symbols are defined as

$$\hat{s}_i = s_i \cdot e^{i\varphi}$$

5.5 Pulse shaping

The modulating symbols $\hat{s}_i$ as represented by Dirac pulses excite one of the following linear pulse shaping filters:

- A spectrally wide pulse shape $c(t)$, where $c(t)$ is the continuous time representation of a discrete time pulse shape $c_n = c((n-1)T_s)$, which is defined in Annex A, where $T_s$ is the sampling period which for the purpose of the pulse shape definition, is $7/16$, and $n = 1, 2, ..., 97$.

The base band signal is
\[ y(t') = \sum_i \delta_i \cdot c'(t' - iT + 2.5T) \]

NOTE: A closed-form expression of \(c'(t)\) is not available because the spectrally wide pulse shape was numerically optimised based on a set of discrete filter coefficients. The continuous time function can be obtained by:

- low-pass filtering the discrete time function with a pass-band of 400 kHz and a stop-band beginning at 2600 kHz and;
- truncating the duration to the time interval \([0, 6T]\).

An example for such a low-pass filter is a raised cosine filter with the impulse response
\[ r(t) = si(2\pi \cdot 2600 \text{ kHz}) \cdot \cos(2\pi \cdot 2200 \text{ kHz})/(1-(4 \cdot t \cdot 2200 \text{ kHz})^2) \]
with \(si(x) = \sin(x)/x\), resulting in
\[ c'(t) = \sum_{n=1}^{97} c_n r(t - (n-1)T_s) \text{ for } 0 \leq t \leq 6T \text{ and } c'(t) = 0 \text{ for } t < 0 \text{ or } t > 6T. \]

- A spectrally narrow pulse shape, \(c_0(t)\), which is the linearised GMSK pulse as defined in subclause 3.5 for the normal symbol period.

NOTE: The linearised GMSK pulse is not scaled to the reduced symbol period. Hence its duration in terms of the reduced symbol period is 6T.

The base band signal is
\[ y(t') = \sum_i \delta_i \cdot c_0(t' - iT + 2.5T) \]

The time reference \(t' = 0\) is the start of the active part of the burst as shown in figure 3. This is also the start of the symbol period of symbol number 0 (containing the first tail bit) as defined in 3GPP TS 45.002.

For the uplink, the pulse shape that shall be used when transmitting a burst is dependent on the parameter ‘Pulse format’ that is sent during assignment (see 3GPP TS 44.060). For the downlink the spectrally narrow pulse shape shall be used.

### 5.6 Modulation

The modulated RF carrier during the useful part of the burst is:
\[ x(t') = \sqrt{\frac{2E_s}{T}} \Re \left[ y(t') \cdot e^{j(2\pi f_0 t' + \varphi_0)} \right] \]

where \(E_s\) is the energy per modulating symbol, \(f_0\) is the centre frequency and \(\varphi_0\) is a random phase and is constant during one burst.

### 6 Modulation format for AQPSK

#### 6.1 Modulating symbol rate

The modulating symbol rate is the normal symbol rate which is defined as \(1/T = 1625/6 \text{ ksymb/s}\) (i.e. approximately 270,833 ksymb/s), which corresponds to \(2^*1625/6 \text{ kbit/s}\) (i.e. 541,666 kbit/s). \(T\) is the normal symbol period (see 3GPP TS 45.010).

#### 6.2 Symbol mapping

The modulating bits are mapped to the quaternary symbols according to Table 5.
Table 5: Mapping between modulating bits and quaternary symbols.

<table>
<thead>
<tr>
<th>Modulating bits for $a_i, b_i$</th>
<th>AQPSK symbol in polar notation $s_i$</th>
</tr>
</thead>
<tbody>
<tr>
<td>(0,0)</td>
<td>$e^{j\alpha}$</td>
</tr>
<tr>
<td>(0,1)</td>
<td>$e^{-j\alpha}$</td>
</tr>
<tr>
<td>(1,0)</td>
<td>$-e^{-j\alpha}$</td>
</tr>
<tr>
<td>(1,1)</td>
<td>$-e^{j\alpha}$</td>
</tr>
</tbody>
</table>

This is illustrated in Figure 5.

Figure 5: Mapping of modulating bits to AQPSK symbols

The ratio of power between the Q and I channels is defined as the Subchannel Power Imbalance Ratio (SCPIR).

The value of the SCPIR is given by

$$SCPIR = 20 \cdot \log_{10} \left( \tan(\alpha) \right) dB.$$  

The value of $\alpha$ shall be chosen such that $|SCPIR| \leq 10 dB$.

### 6.3 Start and stop of the burst

Before the first bit of the burst as defined in 3GPP TS 45.002 enters the modulator, the state of the modulator is undefined. Also after the last bit of the burst, the state of the modulator is undefined. The tail symbols (see 3GPP TS 45.002) define the start and the stop of the active and the useful part of the burst as illustrated in Figure 6. Nothing is specified about the actual phase of the modulator output signal outside the useful part of the burst.
6.4 Symbol rotation

The symbols are continuously rotated with $\varphi$ radians per symbol before pulse shaping, where $\varphi = \pi/2$. The rotated symbols are defined as

$$\hat{s}_i = s_i \cdot e^{j\varphi}$$

6.5 Pulse shaping

The modulating symbols $\hat{s}_i$ as represented by Dirac pulses excite the following linear pulse shaping filter:

- $c_0(t)$, which is the linearised GMSK pulse as defined in subclause 3.5 for the normal symbol period.

The base band signal is

$$y(t') = \sum_i \hat{s}_i \cdot c_0(t' - iT + 2T)$$

The time reference $t' = 0$ is the start of the active part of the burst as shown in figure 6. This is also the start of the symbol period of symbol number 0 (containing the first tail bit) as defined in 3GPP TS 45.002.

6.6 Modulation

The modulated RF carrier during the useful part of the burst is:

$$x(t') = \sqrt{\frac{2E_s}{T}} \text{Re}\left[y(t') \cdot e^{j(2\pi f_0 t' + \phi_0)}\right]$$

where $E_s$ is the energy per modulating symbol, $f_0$ is the centre frequency and $\phi_0$ is a random phase and is constant during one burst.
Annex A (normative):
Tx filter coefficients for the spectrally wide pulse shape

For an oversampling factor of 16, i.e. 5200 ksamples/s, there are 97 Tx filter coefficients \(c_1\) to \(c_{97}\) for the spectrally wide pulse shape. The coefficients are symmetric to \(c_{49}\), i.e. \(c_{49-k} = c_{49+k}\). The coefficients of \(c_1\) to \(c_{49}\) are listed:
